The born surgeon, though he probably would be the first to take advantage of this kind of instruction, can look after himself, for he can pick up what he wants anywhere; but there are not enough born surgeons to go round, and the more ordinary man must be taught the craft of surgery in exactly the same way as a carpenter or stone cutter is taught his particular craft, by learning the use of his tools under a good instructor. In one branch of medicine, dentistry, the necessity of high-class craftsmanship is well understood, and ingenious methods have been devised to teach the student the use of his hands. Dissecting would form a useful link between fundamental craftsmanship and operating first on the dead then on the living.

We are not naturally accurate, we make ourselves accurate because necessity drives us. A painter, if he is an artist, will always try to express himself before he knows anything of the craft of painting; he will force himself to learn to draw and paint, because he finds out the necessity. Perhaps my only valid excuse for daring to write this letter is that I have practised and instructed in two callings, both of which, for their fullest expression, require such infinite labour from the apprentice.

I am, Sir, yours faithfully,
HENRY TONKS.

Slade School of Fine Art, University College, Gower-street, W.C., Nov. 11th, 1929.

BROWN *v.* WHITE BREAD.

To the Editor of THE LANCET.

SIR,—Hartwell and Mottram found that their mice did not do well on an "Essex" diet, that is, a diet based on one which Dr. A. B. Hill found to be an average one for Essex agricultural labourers and their families. Miss Brad and I have been inbreeding a stock of mice for six years and we have found the mice do very well and breed very well on an Essex diet. Our diet consists of meat, 5·8; potatoes, 28·2; greens or peas or beans, 6·2; cheese, 0·8; tangerine, 2·8; sugar, 5·4; rolled oats, 0·8; milk, 8·3; white bread, 41·7. The food is got as cooked for our canteen lunch and is crumbled, shredded, and mixed together, and then minced. No water is added. We have come to regard this diet as excellent for producing fine-looking and well-breeding mice, better than what we call our "mild" diet, three kinds of grain and raw green stuff.

I am, Sir, yours faithfully,
Nov. 9th, 1929. LEONARD HILL.

INTERPRETATION OF FERTILITY TESTS.

To the Editor of THE LANCET.

SIR,—May I make two observations upon the excellent article in your Clinical Interpretation Series by Mr. Kenneth Walker last week. Incompatibility or relative fertility is often due to lack of sexual orgasm in the female with a certain male partner. Women respond with varying intensity to different males, and consequently there is a variation in quantity and quality of their sexual secretions during intercourse. This also explains why a woman will often infect one man with gonorrhœa and not others. In other words she suffers from a type of impotency.

The second point is of great medico-legal importance, particularly in cases of disputed paternity. Mr. Walker quotes the numerical calculations of spermatozoa by Comber and Sanders, and points out that conception very rarely took place when the figure was below 60 million. I would suggest some other factor was operating. Bearing in mind that usually only one spermatozoon penetrates an ovum, and that simply spraying the vulva with semen has caused pregnancy, I at least would hesitate to give a negative reply unless I found 60 million in a specimen.

I am, Sir, yours faithfully,
Harley-street, W., Nov. 9th, 1929. M. W. BROWDY.

THE HEALTH AND CONDITIONS OF WORK OF MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—Mr. Corner cannot, I think, have paid me the compliment of reading my paper, for he entirely misinterprets its purpose.

As Mr. Corner seems under a misapprehension with regard to the object of my address, which was to consider the health and mortality, not the careers, of medical students, I cannot but be doubtful as to whether the papers that he cites, his own and one by Sir Squire Sprigge, would have helped me materially. When I wrote asking for information on my subject, the Dean of St. Thomas's Hospital did not mention Mr. Corner's paper, which Mr. Corner tells me was published in the *St. Thomas's Hospital Gazette*. The Dean of St. George's Hospital similarly did not refer me to Sir Squire Sprigge's contribution regarding St. George's students. Clearly these authorities, who were in a better position than I was to be familiar with the articles referred to—*St. Thomas's Hospital Gazette* is little read outside St. Thomas's—did not regard them as being pertinent to my inquiry.

I am, Sir, yours faithfully,
E. GRAHAM LITTLE.

House of Commons, S.W., Nov. 12th, 1929.

THE DIAGNOSIS OF LARYNGEAL CANCER.

To the Editor of THE LANCET.

SIR,—Mr. Layton has evaded my question as to why my cases illustrated by lantern slides of microscopical sections "afforded a strong argument against biopsies." The cases illustrated the correction of erroneous clinical diagnoses by means of the microscopical examination of portions of tissue removed for the purpose. The assurance afforded by the unmistakable evidence of the microscope led to the prompt adoption of energetic treatment and the preservation of lives which would otherwise have inevitably been lost. Mr. Layton may have justification for his objection to microscopical biopsies, but surely not founded on those cases.

I am, Sir, yours faithfully,
London, Nov. 11th, 1929. JAMES DUNDAS-GRANT.

AVERTIN ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—I hope you will allow me to draw attention to some errors and omissions in your report of my paper on Avertin (THE LANCET, Nov. 9th, p. 979). Firstly, when speaking of the strengths of the solutions used I tried to make it clear that it is the manufacturers who now recommend a 2·5 per cent. in preference to a 3 per cent. solution on the grounds that absorption from a 2·5 per cent solution is more even and gradual but that I preferred the stronger solution for children as the smaller quantity of fluid to be injected is more readily retained by them. Secondly, the sentence beginning "fatal cases" misrepresents me, for only one death occurred in my series of 100 administrations, and I gave reasons for my belief that avertin was not responsible.

The omissions are more serious; no mention is made of the importance of testing the solution for impurities before injection, although this was emphasised. Again, no mention is made of the need for care in dosage, although a considerable part of my paper was devoted to the discussion of this essential; the result is that I am reported as saying that avertin is "a safe means of induction," whereas my statement was that it is safe if used in the doses recommended by Prof. Eichholtz.

I am, Sir, yours faithfully,
FRANCIS SHIPWAY.

York-terrace, N.W., Nov. 8th, 1929.

GENERAL MEDICAL COUNCIL ELECTION.

To the Editor of THE LANCET.

SIR,—Will you grant me the courtesy of your columns to convey to the Registered Medical Practitioners of Scotland my thanks for the renewed expression of their confidence. I shall do my best to deserve it.

I am, Sir, yours faithfully,
Edinburgh, Nov. 11th, 1929. NORMAN WALKER.

ELECTRICAL TREATMENTS IN ACUTE CONDITIONS.

To the Editor of THE LANCET.

SIR,—It is a matter for regret that most electrotherapeutists find difficulty in expressing their thoughts in recognised technical terms, and that they disregard directly appreciable or simple phenomena while in search of explanations for others. The lure of the fantastic seems to divert them from more widely accepted and plausible theories.

On reading Dr. Heald's article in your last issue (p. 974) I could not help feeling shocked at some of his statements and I am loth to let them pass unchallenged. It seems to me that, in a number of ways, the writer of the article on "Electrical Treatments in Acute Conditions" has confused causes and effects. He states that diathermy current is closely allied to the wireless wave. This is true inasmuch as a diathermy machine under requisite conditions may be made to emit electromagnetic waves of the wave-length employed in wireless. Rapidly oscillating electric fields can be made to cause ethereal disturbances and well-tuned circuits will convert these back to oscillating currents; but when diathermy apparatus is employed for electrotherapeutic purposes, the machine is used to create, in the patient's tissues, a rapidly oscillating field. It is conceivable that a small portion of electrical energy is converted into radiant energy of wireless wave-length, but it is doubtful whether those could be reconverted into electrical energy.

That heat is produced in this field is unquestionable, and that a number of phenomena attend this increase of temperature in the living tissues submitted to it cannot be doubted. All changes capable of being accelerated, whether physical, chemical, or biological, are accelerated by an increase of temperature. The viscosity of fluids is lowered, cellular activity is stimulated, and defensive processes, such as phagocytosis, antibody formation, bactericidal power, enzyme actions, &c., which generally have an optimum temperature above the normal body temperature, are stimulated. Why in the face of the extraordinary versatility of this physical agent, heat, should it be necessary to elaborate the fantastic theories which I take the liberty to quote:—

> "It has long been taught that diathermy acts only by heat, and has no specific action due to its wave-length. The very name of diathermy supports this theory. As I have said, however, diathermy currents are practically identical with ordinary wireless waves (one machine I have has a wave-length of 365 metres). This current, therefore, does not primarily belong to the heat, or infra-red, portion of the *ether scale*, but it does make itself manifest as heat after it has been *absorbed*, and to appear as such these waves must have first been absorbed and then changed to *heat waves*" (italics mine).

As it is not usual to classify currents among the electromagnetic waves or for them to be "absorbed," the last sentence is quite incoherent. Nor is it easy to understand the relevance of the sentence in brackets. Perhaps adequate understanding of such terms as "ether scale" and "heat waves" or the possibility of including oscillating currents among forms of radiant energy offer the clue to this. It matters little whether the body tissues act as a resistance to the current, or partly as leaky condensers, or whether actual ionic displacement takes place as opposed to pure electronic motion. I cannot help feeling that it is far more satisfactory to interpret the beneficial action of diathermy as the result of accelerated physiological activity following an increase of temperature.

In another paragraph Dr. Heald talks of "heat waves" given out by hot-water bottles and fomentations, and argues that diathermy currents differ from these in that "their initial structure is such that they can pass through all kinds of tissues whether conducting or non-conducting, and where they meet relatively poorly conducting tissues, such as bone, their change into heat waves is more rapid than in such vascular structures as muscles." Here one has great difficulty in making out whether he is talking of the wireless waves, supposed to be produced by the oscillating currents, or the current itself. If one was meant to understand the former, I venture to say that the different resistances of tissues would have very little influence on the amount of heat produced, unless some obscure phenomenon of cellular resonance were to interfere. To advance theories on this subject, without further evidence of this occurring, would be speculating and inviting further criticism. On the other hand, if Dr. Heald means that diathermy currents produce more heat in bones than in other tissues, he is right, always providing he does not give the current an alternative path of less resistance.

I am, Sir, yours faithfully,
Wimpole-street, W., Nov. 11th, 1929. PH. BAUWENS.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

ACCIDENTS IN MINES.

IN the House of Commons on Nov. 6th Mr. GORDON MACDONALD moved:

> "That this House deplores the heavy loss of life and the large number of non-fatal accidents in coal mines, and is of opinion that every possible step should be taken without delay to secure the fullest protection possible to those engaged in this dangerous industry."

He said that in the two years preceding the extension of working hours the rate per 1000 of fatal accidents was 1·11 in 1924 and 1·15 in 1925. In 1927—the year after the Eight Hours Act was passed—the figure was 1·25 and in 1928 it was 1·18. That showed that the Government had made things worse as regarded the number of accidents. The only hope of dealing effectively with the matter was to reduce the working day to the point at which it stood before the passing of the Eight Hours Act. In 1924 the non-fatal accidents numbered 11,937; in 1925 they were 10,622. The rate per 1000 worked out for 1924 at 158·8 and for 1925 159·3. In the two years immediately following the total was 9338 and 8347 respectively and the rates per thousand were 167·2 and 170. Between 1925 and 1928 there had been an increase of 11 per 1000 in non-serious accidents, and the same applied to serious accidents. He did not say that the increase per 1000 in the number of accidents was a direct result of the eight hours working day, but he suggested that the increased working hours was a matter which should be carefully examined in this connexion. Apart from the injuries to the body of miners caused by accidents they had to deal with the very serious menace known as nystagmus. At present there were 9775 men in this country suffering from that disease, which endangered the physical and nervous strength of every sufferer. It was about time that something was done in regard to these men. When they made a slight recovery and were able to do some light work they found themselves faced with total unemployment. The bulk of the regulations governing the life of miners to-day were made in 1911. Since that date mining life, especially underground, had been revolutionised as a result of the introduction of mechanism. The Government might consider seriously taking legislative action to deal with the situation. They might, if necessary, appoint a committee of inquiry for the purpose of consolidating all the statutory orders since 1911 and then produce an up-to-date Mines Regulation Act.

Mr. ROWSON seconded the motion.

Dr. ETHEL BENTHAM said there was no doubt about the enormous incidence of accidents, both fatal and otherwise, on the mining community. She was not an expert in the management of mines, but she had found during her fairly long experience that in many trades piece rates were responsible, not only for accidents, but for ill-health among the workers as well as for a great deal of indifferent work. The workers in every trade with which she was conversant—and she knew a good deal about the conditions in many of them—always said that accidents occurred late in the working day. They ought to consider very carefully the effects of over-long hours in such a laborious, difficult and dangerous trade as mining. She thought that most members of the medical profession—she could not speak for the whole—agreed that it was the posture and the lighting conjointly which were the cause of nystagmus, and it seemed to her that it would be possible by concerted action to get really disinterested evidence on that matter and to take measures to put an end to a disease which was quite preventable if they were ready to consider the lives of men, women and children, and the national advantage of good health instead of the narrow financial aspect of the matter which precluded sufficient money being spent on the prevention of the disease and on experiments with a view to such prevention.

The Government's Reply.

Mr. BEN TURNER, Secretary for the Mines Department, replying for the Government, said that the recorded accidents in 1928 were less than in the years before, but he had no such comfort to offer for this year. Up to 1929 the numbers were the lowest since 1860, but during the first nine months of this year they had gone back to the old rate of over 1000 persons killed each year. It was also certain that there were many unrecorded accidents. It was true that the death-rate in our pits was less than in America and Germany. That, however, was little comfort to those who lost their breadwinner, and all parties in the State were anxious, if possible, to assist in the reduction of these accidents. He wondered sometimes if the unsettled economic and other conditions in the coalfields had added to the heavy loss of life and limb. He was quite certain that there had been no slackness in the Mines Department with regard to protective measures. The rate, however, was so terrible that every effort must be made to bring about a great reduction. The present strength of the mining inspectorate was 106, including eight special inspectors who devoted the whole of their time to the inspection of pit ponies. The number of mines in 1922 was 2911 and the employees 1,163,754. Last year the number of mines was 2530 and the number of employees 951,000. In 1922 the number of inspections was 18,911; last year it was 21,718. The average number of inspections of every mine per year was 7·2 underground and 1·5 on the surface. He was certain that the new electrical development in mines called for more skilled electrical inspectors. Since 1912, when 600,000 horse power was being applied to pits, the amount had grown to 1,750,000 horse power. There was a great risk in the use of this new agency, and it required attention. To relieve the situation he hoped to appoint four additional electrical inspectors of mines. The difficulties in the way of revising legislation for the mines were twofold. In the first place, the various sections of the industry were all too preoccupied with labour and economic conditions to give it the detailed attention and constructive criticism which the Department needed. In the second place, the Government were so fully occupied with prospective legislation in this and other matters that it was impossible to overcome delay. In connexion with the code of regulations for first-aid and ambulance work he thought that delay had been caused by the procedure which was not as speedy as it should be. The practice had been to send the draft regulations to the Mining Association; then they came back to the Department, which sent them to the Miners' Federation. He saw no reason why the two sides of the industry should not meet and decide upon the best regulations instead of passing a draft backwards and forwards as had been done hitherto. Many accidents could be avoided with more care and expenditure—care on the part of the management, the officials and the men, and expenditure on the part of the owners. Accidents arising from falls of roof and from haulage were the heaviest in each week's return, and this had caused the Mines Department, through the Mines Research Board, to appoint a highly qualified specialist to organise and superintend further experimental work on these subjects and generally to assist the Safety in Mines Research Board in regard to the important mechanical problems in mines. The Department was doing much in the direction of propaganda. He hoped also that science would succeed in producing a lamp giving a safe light with a bigger candle power, which would preserve the miner's eyesight and help to make his production better. In conclusion Mr. Turner assured the House that all the suggestions put forward in the debate would receive careful consideration with a view to the promotion of safety and comfort for men in the coal pits.

The motion was agreed to.

HOUSING BILL.

On Monday, Nov. 11th, Sir R. GOWER presented a Bill to make better provision for the improvement of unhealthy areas; to provide adequate compensation for business disturbance; and to make certain consequential amendments to the Housing Act, 1925.

ILLEGITIMATE CHILDREN IN SCOTLAND.

On Nov. 12th the Duchess of ATHOLL obtained leave to bring in a Bill to amend the law regarding the duration and recovery of aliment for, and the custody of, illegitimate children in Scotland. She explained that the Bill would make the father liable for aliment until the child was 16. The mother was also given power to make application for the expenses of her confinement as well as for aliment within three months of her expected confinement, although if the case were defended by the father the decree could not become operative until after the birth of the child.

Among the backers of the Bill was Major ELLIOT.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 6TH.

Rheumatic Diseases and Pulmonary Tuberculosis in the Navy.

Dr. VERNON DAVIES asked the First Lord of the Admiralty if he was aware that in 1927, out of a total of 20 men invalided for rheumatic fever, 17 had served for less than two years and that out of a total of 79 men invalided for organic heart disease 40 had served for less than two years; and if he could offer any explanation for this high incidence of rheumatic diseases.—Mr. ALEXANDER replied: The answer to the first part of the question is in the affirmative. It is not considered that the incidence of rheumatic diseases is unduly high when consideration is given to the early age at which recruits are received into the Navy.

Dr. VERNON DAVIES also asked how many of the 159 men invalided from the Service in 1927 for pulmonary tuberculosis were granted disability pensions; in how many cases was the disease held to be attributable to the conditions of service; and how these numbers compared with those of the previous three years, expressed as a percentage of the number pensioned to the total number of cases.—Mr. ALEXANDER replied: The number of men invalided in 1927 for tuberculosis was 180, and pensions on the attributable scale were granted in 18 cases, or 10 per cent. of the total. This compares with 3 per cent. in 1926, 1 per cent. in 1925, and 3 per cent. in 1924. In a considerable number of cases pensions on the non-attributable scale were granted where the men had sufficient service to qualify.

Dr. DAVIES: Will the right hon. gentleman observe that the percentage of pensions granted has increased rapidly this year, possibly to the too great restrictions on previous years, and would he be prepared to look over some of the back cases to see if the present conditions on which pensions are granted are applicable to cases which have been previously refused.

Mr. ALEXANDER: I shall be glad to consider any representations of a specific character made to me. It is obviously difficult to go back on decisions which have been made under regulations which existed at that time, but I will consider it.

Mr. HORE-BELISHA: While the figures show an improvement under the revised rules, is not the necessity for an appeal tribunal still apparent?

Mr. ALEXANDER: As far as I have been able to look into the matter there is a considerable improvement in the method in which these cases are dealt with, but I have had no strong case put to me yet for an appeal tribunal, and, in fact, I am not at all sure that in the regular Service cases an appeal tribunal would always be to the advantage of the men. I hope that the hon. Member will consider that.

Vaccination of Naval Personnel.

Mr. MOSES asked the First Lord of the Admiralty how long it had been the practice to carry out quinquennial revaccination, as necessary of all personnel in the Navy; whether such revaccinations were compulsory; and whether he proposed to make any changes in the Navy regulations relating to the vaccination of naval recruits and dockyard apprentices under the age of 19 years who had not previously been vaccinated, in view of recent cases among the civil population of post-vaccinal encephalitis.—Mr. ALEXANDER replied: It has been the practice to carry out quinquennial revaccination of personnel of the Royal Navy when going abroad, for many years. An order was [illegible] on Sept. 7th, 1928, that revaccination of active [illegible] personnel should be carried out every five years (A[illegible] Fleet Order, 2210/28). No punishment or [illegible] incurred for declining revaccination on cons[illegible] other grounds, but precautions are taken to pr[illegible] revaccinated from becoming a danger to the Service by landing in ports where there is danger of contracting small-pox (King's Regulations and Admiralty Instructions 1417/12). It is not proposed at present to make any changes in the Navy regulations relating to the vaccination of Naval recruits, in view of the fact that these young men are likely to be exposed to the danger of infection by the severe Oriental type of small-pox as soon as they go to sea. The regulations relating to the vaccination of dockyard apprentices are under consideration.

Civil Service and Scientific Research.

Lieut.-Colonel Fremantle asked the Prime Minister if it was the intention of H.M. Government, in appointing the Royal Commission on the Civil Services, to review the status and functions of the large body of scientific and technical experts engaged in the Civil Services, with a view to the furtherance of scientific knowledge, methods, and research of those services; and if, seeing that there was no representative of science nor anyone engaged in the application of science to the needs of the community, he would consider the addition to the Royal Commission of a due proportion of such representatives.—Mr. Snowden, Chancellor of the Exchequer, replied: The Royal Commission has been appointed to inquire into and report on the structure and organisation of the Civil Service, conditions of employment of Civil Servants, and conditions of retirement from the Civil Service. Its terms of reference have been widely drawn and it will be for the Commission itself to determine the extent to which the various subjects within the scope of the reference can profitably be reviewed. I am satisfied that the Commission as now constituted is well adapted to the purposes of the inquiry and I am not prepared to enlarge its numbers.

Colonial Veterinary Scholarships.

Mr. Ormsby-Gore asked the Under-Secretary for the Colonies whether the proposed school of tropical veterinary medicine, recommended by Lord Lovat's Committee, would now be established; and what steps were being taken to improve the recruitment and training of veterinary officers for service under Colonial Governments.—Mr. Lunn, Parliamentary Under-Secretary for the Colonies, replied: A decision on the recommendation of Lord Lovat's Committee on the Colonial Veterinary Services for the establishment of a school of tropical veterinary science was deferred until the Report of the Departmental Committee on the reconstruction of the Royal Veterinary College at Camden Town was available. This report has now been issued, and the question will be further considered in the light of the recommendations contained in it. It is hoped that it will be possible to bring the proposed Colonial Veterinary Scholarship Scheme into operation next year. All the Colonial Governments which were asked to contribute towards the expenditure involved have agreed to do so, and the Colonial Development Advisory Committee are now considering an application for a grant from the Colonial Development Fund to meet the one-third of the annual cost of the scholarships which was the portion that Lord Lovat's Committee recommended should be provided from United Kingdom funds.

Motorists and Third-party Insurance.

Sir Gervais Rentoul asked the Minister of Transport whether he was prepared to introduce legislation for the compulsory third-party insurance of all motor vehicles.—Mr. Herbert Morrison replied: The desirability of requiring that the driver of a motor vehicle should obtain cover against any legal liability that may attach to him in respect of the death of, or bodily injury to, another person will be most carefully borne in mind in connexion with any Road Traffic Bill which I may be in a position to present to Parliament.

Stationary Cars and Road Accidents.

Sir Alfred Knox asked the Minister of Transport if he would, in order to prevent a frequent cause of accidents, insert in the Transport Bill the provision that cars drawing up at the side of the road after lighting-up time must be pointed in the same direction as the traffic on that side.—Mr. H. Morrison replied: I have under consideration the inclusion in any legislation that may be introduced to deal with road traffic of a provision making it an offence to leave a motor vehicle in a position dangerous to other traffic using the road. In the case of a well-lighted street a general provision of the nature suggested by the hon. Member might cause unnecessary inconvenience, and even danger, owing to the necessity of reversing vehicles in order that they might point in the proper direction.

Proposed Extension of Milk and Dairies Order.

Mr. Lawther asked the Minister of Health if he would take the necessary steps to extend the Milk and Dairies Order, 1926, to the housing of calves and young cattle, as it was held that this might help towards preventing the spread of tuberculosis.—Miss Lawrence, Parliamentary Secretary to the Ministry of Health, replied: Although my right hon. friend agrees as to the importance of the proper housing of calves and young cattle, it seems to him that the safeguarding of the health of such animals is too remote from the objects of the Milk and Dairies Order to justify him in extending the provisions of that Order in the manner suggested.

Insurance Committees and Health Lectures.

Dr. Morgan asked the Minister of Health how many insurance committees had taken advantage of the provisions of the National Health Insurance Acts and instituted lectures on health and disease prevention for the insured persons in their district; how many such lectures had been given this year and at what cost; and whether any steps were proposed to remind insurance committees of their obligations in this respect.—Mr. Greenwood replied: I am not in possession of any precise figures on the points raised in the first two parts of the question; but I am aware that certain committees have undertaken work of this character. It is not obligatory upon committees to do so, and I think they are already fully acquainted with their statutory powers.

Care and Management of Infants.

Dr. Hastings asked the Minister of Health whether he would consider the presentation of a booklet through the local authorities on the care and management of infants to the parents of every child at the time that its birth was registered.—Mr. Greenwood replied: It is the common practice for local authorities to arrange for the distribution of booklets of this kind to parents by health visitors and at infant welfare centres, and I do not therefore consider it necessary to take the action suggested by my hon. friend.

Leaflets on Treatment of Disease.

Dr. Hastings asked the Minister of Health whether his attention had been called to the amount of disease which was preventable or readily curable if treated in its earliest stages; and whether he would consider the advisability of the provision of leaflets dealing with human disease, similar in nature to the leaflets provided by the Ministry of Agriculture regarding the diseases of animals and plants.—Mr. Greenwood replied: I am aware of the facts referred to in the first part of the question. My Department have, from time to time, issued memoranda dealing with the prevention and treatment of various diseases, and further memoranda of the same character will be issued as occasion requires. These memoranda are on sale to the public, but they are primarily designed for the information of local authorities and their officers, and in some cases may conveniently form the basis for the popular leaflets or public announcements issued by such authorities.

Vacancies for Colonial Veterinary Officers.

Mr. Ormsby-Gore asked the Under-Secretary of State for the Colonies if he would state how many unfilled vacancies now existed for veterinary officers and veterinary research officers in the Colonies, Protectorates, and Mandated Territories.—Mr. Lunn replied: Apart from the consequential vacancies which will be caused by promotions now under consideration there exists at the present time one vacancy for a veterinary officer.

Pensions of Indian Medical Officers.

Mr. Wedgwood Benn, Secretary of State for India, in reply to Major Graham Pole, stated that the number of officers of the Indian Medical Service who drew pensions through the India Office chargeable to Indian revenues during the year ended March 31st, 1929, was 551, and the amount paid during the year in respect of these pensions was £310,960.

THURSDAY, NOV. 7TH.

Cancer among Industrial Workers.

Mr. Philip Oliver asked the Home Secretary whether he had yet been able to take any and, if so, what steps to facilitate the investigation at present being carried out by the London Cancer Hospital into the incidence of the disease of cancer of the bladder among workers in aniline factories.—Mr. Clynes replied: Yes, Sir. I am arranging for the coöperation of the Medical Inspectorate of the Factory Department in the investigation of the industrial history of cases of this disease; and I am also consulting the Registrar-General on the question of facilitating the supply of the statistical information required.

Escape of a Mental Patient.

Mr. Lang asked the Home Secretary if his attention had been drawn to the escape from Devizes Mental Hospital of a patient named Littleton Watson; if he was aware that this patient was transferred to Devizes from Broadmoor criminal lunatic asylum a year ago; and if he would state the conditions under which such transfers were made.—Mr. Clynes replied: I have seen a newspaper report. The escape of a patient who is not a criminal lunatic would not be reported officially to me. The patient in question, while under sentences for stealing and false pretences, was certified insane and removed to Broadmoor, as a criminal lunatic. When his sentences expired in October, 1928, he ceased to be a criminal lunatic; but as he was still insane, he was recertified under the ordinary lunacy law and received into the Devizes Mental Hospital. This is the course prescribed by statute.

Experiments on Living Animals.

Mr. Freeman asked the Home Secretary if he would give instructions that a record be kept of the kind of animals used for each experiment in vivisection, the total period during which each animal was experimented upon, and the actual time during which it suffered any kind of pain; and that this information be published in future reports.—Mr. Clynes replied: No, Sir. I do not think that the information suggested, even if it were obtainable, would serve any useful purpose. So far as the question of pain is concerned, I would remind my hon. friend that stringent conditions are imposed in all cases in which the experiment is performed without anæsthesia or the animal is allowed to come out of the anæsthesia.

Health Conditions in Artificial Silk Works.

Mr. Kelly asked the Home Secretary what action had been taken to improve the health conditions in the spinning rooms of artificial silk factories, particularly in the matter of eye injury and lung trouble; and if any prosecution had taken place against firms in this industry during the last six months.—Mr. Clynes replied: The matter has continued to receive the close attention of the inspectorate, and the further conference which I mentioned in my reply to my hon. friend on July 25th last was held last month. It was agreed that the remedy for the special trouble arising in the spinning rooms is to secure efficient ventilation, and the inspectors and occupiers are concentrating on this. In many cases improvements have been effected with beneficial results. The conditions in all these works will continue to receive close supervision. One prosecution has taken place during the last six months, the offences being failure to ventilate the churns and failure to notify cases of poisoning by carbon bisulphide. Substantial penalties were imposed.

Supply of Milk at Maternity Centres.

Mr. Fison asked the Minister of Health whether any applications had been made by local authorities for approval of additional expenditure for providing increased allowances for milk at maternity centres; whether such applications had been granted; and what was the amount of such additional expenditure approved.—Mr. Greenwood replied: Sixteen such applications have been received since June last up to the present date, of which ten have been wholly granted and one in part. The remaining five applications are under consideration. The additional expenditure already approved amounts to £1513, while the total amount under consideration is £1973.

Nursery Schools.

Dr. Hastings asked the President of the Board of Education how many of the 20 existing and 15 contemplated nursery schools were open-air schools; and whether he proposed to sanction any further nursery schools not of the open-air type.—Sir Charles Trevelyan replied: Of the 29 existing nursery schools, 28 are open-air schools and nearly all the others have good open-air facilities. The importance of securing the provision of a largely increased number of nursery schools is so great that some latitude must be allowed, as, for example, where it is proposed to adapt an existing building for the purpose, but the majority of the new schools will be of the open-air type.

Public Cleansing in London.

Major Kindersley asked the Minister of Health whether the Departmental Committee appointed to consider the Report of an investigation into the public cleansing service in the administrative county of London had yet made its Report; and whether that Report would be published.—Mr. Greenwood replied: The work of the Departmental Committee has been delayed by the unfortunate death of its chairman, Sir John Gatti, to whose public services, though I differed from him on many matters, I should like to pay my tribute. A new chairman is to be appointed, and I hope that the Committee will find it possible to make an early Report, which will pave the way to dealing with this pressing problem on effective and comprehensive lines. I see at present no reason why their Report should not be published. I can assure the House that the Government are impressed with the necessity for action, and I propose to confer with the Committee at an early date. I do not think that it would help matters to add to the Committee representatives of areas in which dumps are situated. I understand that the Committee have already considered a large part of their problem and have visited some of the dumps.

Non-Pulmonary Tuberculosis.

Dr. Hastings asked the Minister of Health the number of deaths from tuberculosis of other organs than the lung that occurred in 1928; and if any estimate had been made of the number of these deaths that resulted from infection by tuberculous milk.—Mr. Greenwood replied: Of the registered deaths in England and Wales in 1928 classified to tuberculosis, 6834 were assigned to forms of the disease other than pulmonary tuberculosis. I am advised that there is no information available on which to base any reliable estimate of the number of these deaths which were due to infection by tuberculous milk.

Derating and Voluntary Hospitals.

Mr. Wardlaw-Milne asked the Minister of Health whether it was the intention of the Government to introduce legislation extending the benefits of derating to the voluntary hospitals.—Mr. Greenwood replied: It is not at present the intention to introduce such legislation. It would not be practicable to propose the total or partial exemption of hospitals from rating without at the same time considering the claims for similar exemption of other charitable and public institutions.

Lunacy Law Reform.

Viscount Elmley asked the Minister of Health whether he intended to revise the Lunacy Laws; and, if so, when the proposals would be brought forward.—Mr. Greenwood replied: I hope that it may be practicable in the near future to introduce a Bill to effect certain improvements in lunacy law and administration.

Government and Slum Clearance.

Mr. Albery asked the Minister of Health whether he anticipated that the Government's scheme for slum clearance was likely to be in operation within the next 12 months.—Mr. Greenwood replied: Yes, Sir.

Lieut.-Commander Kenworthy asked the Minister of Health the total number of slum clearance schemes carried out during the years 1925 and 1928 inclusive; and what was the total number of persons rehoused under these schemes.—Mr. Greenwood replied: In the period from 1925 to 1928 work was in progress on 118 slum schemes, some of which had been started prior to 1925. The total number of people to be rehoused in connexion with these schemes was 71,418. In the case of 61 schemes the work of rehousing was completed during the period and provided accommodation for 20,746 persons.

Dr. Morgan asked the Minister of Health if he was aware that many persons in the south-east of London were being summoned or being prosecuted for overcrowding; and whether, in view of the prevailing conditions, over which these poor people had no control, he would seriously consider the advisability of issuing a circular letter to metropolitan local authorities requesting them to delay any such proceedings pending the introduction of his promised Slum Clearance Bill.—Mr. Greenwood replied: My hon. friend has brought some particulars to my notice. I have no power to give directions to the local authorities to refrain from action in cases which they consider they should bring before the courts.

Medical Services in Naval and Military Forces.

Dr. Vernon Davies asked the Secretary to the Treasury what progress had been made by the joint medical services committee of the Navy, Army, and Air Force in establishing a common system of costing with regard to hospitals.—Mr. Pethick-Lawrence replied: The experiments which have been tried for the past two and a half years are still in progress; but it has not yet been found possible to devise a common form for use in all the Services which will give satisfactory results.

Pulmonary Tuberculosis in the Services.

Dr. Vernon Davies asked the Secretary to the Treasury if the joint medical committee of the three Service departments and the Ministry of Pensions appointed to inquire into the relationship between conditions of Service life and pulmonary tuberculosis had come to any decision; if any report had been submitted; and, if so, if it would be available for the information of the House.—Mr. Ammon replied: The committee have reported, and as a result of certain recommendations made by them various steps are being taken by the Departments concerned. The answer to the last part of the question is in the negative.

Hysteria in Dogs.

Colonel Clifton Brown asked the Minister of Agriculture if he was aware that the comparatively new disease of hysteria was seriously affecting sheep-dogs and other dogs in this country; and what steps his department was taking to investigate the cause of this ailment and to find a cure.—Dr. ADDISON, Parliamentary Secretary to the Ministry of Agriculture, replied: I am aware of the occurrence of hysteria among dogs in this country, and although no cases in sheep-dogs have been brought to my notice, they are probably susceptible to the condition. Research into the disease is in progress at the Royal Veterinary College.

The Royal Veterinary College.

Captain CROOKSHANK asked the Minister of Agriculture if he could make any statement regarding the future of the Royal Veterinary College.—Dr. ADDISON replied: My right hon. friend has received the Report of the Committee which was appointed by his predecessor to consider the whole problem of the reconstruction of the Royal Veterinary College. The Report raises important and difficult questions which are now receiving his careful consideration, and a further statement on the subject will be made in due course.

Sounding Motor Horns at Night.

Colonel HOWARD-BURY asked the Minister of Transport whether he was aware that in Paris during certain hours of the night no motor horns were allowed to be sounded; and whether he would put in force a similar order in the London metropolitan area.—Mr. H. MORRISON replied: Although traffic conditions in London differ materially from those prevailing in Paris, I am having inquiries made with a view to ascertaining whether the principle adopted in Paris of prohibiting the sounding of motor horns during certain hours of the night in certain parts of the city would be suitable for experimental trials in some portion of the metropolitan area.

Voluntary Hospitals and Recovery of Expenses.

Major EDMONDSON asked the Minister of Transport whether his attention had been called to the position of voluntary hospitals with regard to their right to recover expenses in cases where the personal damage suffered by patients had been assured against; and whether he was prepared to take steps to introduce legislation, if necessary, to remedy the present position.—Mr. H. MORRISON replied: I am aware that the voluntary hospitals incur considerable expenditure in the treatment of motor accident cases, but I do not think that it would be practicable or desirable to provide that they should have a special legal claim to a proportion of insurance moneys in those cases where the injured person is compensated out of such moneys.

MONDAY, NOV. 11TH.

The Tuberculosis Order, 1925.

Mr. LAWTHER asked the Minister of Agriculture if he would give the figures of the number of animals slaughtered under the Tuberculosis Order, 1925, in the counties of Northumberland, Durham, Cumberland, and the North Riding of Yorkshire for the year ending December, 1928; and if he was satisfied that proper precautions existed to prevent those carcasses being used for human consumption.—Mr. BUXTON replied: The number of animals slaughtered in the counties named during 1928 under the Tuberculosis Order of 1925 was: Northumberland, 92; Durham, 210; Cumberland, 152; and North Riding, 320. The carcasses of animals slaughtered, for which compensation is paid to the owner, become the property of the local authority, and the Order of 1925 (No. 2) provides that no parts of such carcasses shall be removed for consumption without the written permission of the medical officer of health or other competent officer of the sanitary authority. I am therefore satisfied that the proper precautions exist.

Grants for Maternity and Child Welfare.

Lieut.-Colonel HENEAGE asked the Minister of Health what grant he proposed to make towards maternity and child welfare services.—Miss LAWRENCE, Parliamentary Secretary to the Ministry of Health, replied: It is estimated that the total grant payable during the present financial year in respect of these services will be about £1,170,000, as compared with £1,071,500, the total grant paid last year.

Asbestos Workers and Workmen's Compensation.

Mr. STAMFORD asked the Home Secretary whether he had received a report of the coroner's inquest on Abraham Jowett, a charge hand at Messrs. J. W. Roberts' asbestos works at Armley, Leeds, whose death was certified as being due to acute lobar pneumonia, contributed to by fibrosis due to asbestosis; and whether, in view of the risks to which workers in asbestos were exposed, he intended to schedule the disease under the Workmen's Compensation Acts.—Mr. SHORT, Under-Secretary to the Home Office, replied: Yes, Sir. My right hon. friend has received a report on this case from the inspector who attended the inquest. The risks to which workers in asbestos are exposed have been the subject of a comprehensive inquiry by the Factory Department, and my right hon. friend hopes to be in a position very shortly to consider what further precautions are necessary for the protection of the workers. The question of compensation will be considered at the same time. At the present moment he cannot make any statement on the subject.

Noxious Fumes from Cement Works.

Mr. MILLS asked the Minister of Health if he had received complaints of noxious and vegetable-destroying fumes from cement works on the banks of the River Thames; and, if so, what action was contemplated.—Miss LAWRENCE replied: Complaints have been received regarding the emission of dust. An inspector of my department has made investigations. In one case, steps have been taken to reduce the emission and the matter is continuing to receive attention. In the other case, the inspector reported that he was satisfied as to the result of the steps which had been taken.

Mr. MILLS asked the Home Secretary the measures taken to prevent nuisances by wasteful fumes from cement factories; and the comparative waste as between German works and British works.—Miss LAWRENCE replied: The emission of fumes is usually kept well in hand; the emission of dust gives more trouble. A good deal has been done and experiments are being conducted for dealing more effectively with the problem. Inspectors of my Department are in close touch with what is being done. I cannot at present say how works in this country compare with those in Germany.

Wards at Broadmoor Asylum.

Mr. OLIVER BALDWIN asked the Home Secretary whether he was aware that at Broadmoor Criminal Lunatic Asylum there was a special ward where prisoners of the richer classes were segregated; and, if so, whether he would discontinue this method of class distinction.—Mr. CLYNES replied: There is no such special ward at the asylum.

Blind Persons in England and Wales.

Mr. CLYNES, Home Secretary, informed Mr. KELLY that on March 31st last the number of blind men and women registered under the Blind Persons Act, 1920, in England and Wales was 48,108.

TUESDAY, NOV. 12TH.

Properties in Insanitary Areas.

Sir ROBERT GOWER asked the Minister of Health the number of persons who owned properties in the respective areas represented by local authorities to be insanitary, schemes relating to which had been submitted to him and awaited his approval, and the number of persons owning businesses in such areas respectively.—Mr. GREENWOOD replied: The following statement gives the information desired:—

Local authority.	Scheme.	Persons owning properties in the area and lessees of such properties.	Persons carrying on businesses in the area.
Metropolitan Borough Councils—			
Bethnal Green ..	Digby Street.	13	4
Bermondsey	Rotherhithe Street (West)	21	21
Wandsworth ..	Wandsworth Plain.	35	28
County Borough Councils—			
Bristol	Dings Area.	42	13
Exeter	No. 4 area reconstruction scheme.	5	6
Ipswich	Currier Lane, &c.	55	12
West Bromwich ..	Cooper Hill Street, &c.	32	None so far as is known at present.
Borough Council—			
Wisbech	Carpenter's Arms Yard, &c.	17	5
Urban District Council—			
Knaresborough ..	Beech Hill.	6	3

Slum Clearance Schemes.

Sir ROBERT GOWER asked the Minister of Health what schemes relating to alleged insanitary areas had been submitted for his approval by local authorities during the past five months; and what his decision in each case, respectively had been.—Mr. GREENWOOD replied: During the last five months schemes of this kind have been submitted by the corporations of Bethnal Green, Bristol, Wandsworth, and Wisbech. These schemes are still under consideration.

Medical Examination of Young Mining Workers.

DR. VERNON DAVIES asked the Secretary for Mines if he proposed to take steps to ensure that all young persons under 18 years of age entering the mining industry should be medically examined for fitness before starting work.—Mr. BEN TURNER replied: I understand that medical examination of young persons is one of the matters now under consideration in connexion with a new Factories Bill. When this Bill has become law I will consider whether any change is necessary in mining legislation to bring it into conformity with factory legislation in this respect.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the Final Examination held from Oct. 7th to 30th the following candidates were approved in the undermentioned subjects, but are not eligible for diplomas:—

Medicine.—A. H. Baker, Manchester; J. C. Banerjee, Guy's; A. Barber, St. Bart.'s; K. C. Bhattacharyya, St. Thomas's; R. O. Brooks, Manchester; D. S. Chowdhary, London; R. E. S. Dalliwall, Cambridge and St. Bart.'s; E. Dikshitulu, Madras and Charing Cross; Sheila J. Ferguson, King's Coll.; E. C. I. Foot, Sheffield and St. Bart.'s; J. F. Galpine, Leeds; R. K. Goyal, London; Charlotte Gray, Univ. Coll.; R. S. Harrison, Guy's; Aureval Heaton, Royal Free; Katherine M. Heberlet, Univ. Coll.; Gladys M. Herbert, St. Mary's; G. L. Johnson, Columbia; E. O. Lakey, Univ. Coll.; P. A. E. Lansel, Middlesex; A. Liberis, St. Bart.'s; K. M. Macleod, Edinburgh; J. S. MacVine, St. Bart.'s; R. S. Mann, Univ. Coll.; E. K. Menon, Birmingham; B. B. Nanavatty, Royal Free; F. J. Napier, Guy's; G. L. Ormerod, Cambridge and St. Thomas's; C. H. Paull, Bristol; S. L. Rikhye, London; S. L. Robert, Birmingham; B. P. Robinson, Manchester; L. K. Robson, Guy's; J. Ross and H. K. Said, Charing Cross; J. Sakula, Middlesex; R. L. Sethi, London; Edna F. Sheridan, King's Coll.; H. Silverstein, St. Bart.'s; G. H. G. Southwell-Sander, St. Thomas's; R. G. Sowter, Guy's; Ada M. W. Stewart, Univ. Coll.; T. S. Stone and K. T. Tasker, London; P. H. Taylor, King's Coll.; Rose E. Williams, Royal Free; R. A. Wilmshurst, St. Thomas's; G. R. H. Wrangham, St. Mary's; and F. C. A. Wright, King's Coll.

Midwifery.—G. L. Alcock, St. Thomas's; Katharine M. Allen, King's Coll.; S. Amir-ud-din, Lahore; W. T. Andrews, St. Thomas's; Lily Arratoon, Royal Free; P. B. Ascroft, Middlesex; W. I. Bain, St. Thomas's; A. H. Baker, Manchester; W. L. H. L. Bell, St. George's; J. N. Bhada, Univ. Coll.; F. K. Boston, St. Bart.'s; A. D. Bourne, St. Mary's; A. E. Bowling, Leeds; Mabel Brewster, Royal Free; W. J. Burgess, St. Bart.'s; M. L. Bynoe, King's Coll.; E. C. Campbell and H. Canwarden, St. Mary's; L. Charney and D. N. Chatterji, London; W. F. Church, St. Bart.'s; D. O. Clark, St. Thomas's; Charlotte A. G. Conway, Royal Free; J. S. Cotman, St. Mary's; W. C. Creedee, St. George's; H. D. Cronyn, St. Mary's; H. J. Croot, Guy's; R. M. S. Cross and R. E. S. Dalliwall, St. Bart.'s; Elizabeth T. Davies, Westminster; H. L. G. Davies, St. Bart.'s; V. Dellal, Manchester; D. Divine, Guy's; S. Durham, London; J. M. Durr, Guy's; J. J. Eapen, Madras; Sheila J. Ferguson, King's Coll.; Doreen P. Firmin, Westminster; J. P. Flanagan, Liverpool; A. A. G. Flemming, Cambridge and Bristol; P. Frankenberg, St. Bart's; K. Ghosh, Royal Free; E. J. Goldsmith, St. Thomas's; Rebecca Goldstein, Univ. Coll.; R. W. Graham-Campbell, St. Bart.'s; E. R. Greathead, London; Sheila M. Harper, Liverpool; J. O. Harrison, St. Bart.'s; R. S. Harrison, Guy's; J. E. M. Harrison and R. M. Harvey, London; Katherine M. Heberlet, Univ. Coll.; J. R. Heming, St. Thomas's; J. E. R. Heppolette, St. Mary's; L. Hershfield, Middlesex; J. R. Hindmarsh, Durham; Constance M. Hoare, King's Coll.; R. S. Hodge and Laura M. Hollingworth, Univ. Coll.; S. W. Holmes, St. Mary's; D. W. Hoodless, Charing Cross; H. R. Hovahn, King's Coll.; Eugenie C. Illingworth, Leeds; B. Isaac, St. Mary's; H. B. Jackson, Middlesex; W. J. Johnson, Guys'; M. M. St. G. Johnstone and G. L. Jones, St. Thomas's; I. G. Jones, Univ. Coll.; Alison F. Z. Judd, Royal Free; F. B. Kantzer, Chicago; J. D. Kershaw, Univ. Coll.; J. S. Knox, St. Bart.'s; F. P. L. Lander, Middlesex; G. F. Langley, Bristol; Annie Lawson, Royal Free; S. R. Ledger, King's Coll.; D. H. Le Good, St. Thomas's; G. S. R. Little, St. Bart.'s; L. Lodge, London; J. Loofe, Leeds; V. J. Lopez, St. Mary's; S. H. Lubner, London; Marjorie N. Lunn, Royal Free; G. D. McLean, St. Thomas's; K. M. Macleod, Edinburgh; F. G. Maitland, St. Thomas's; H. S. A. Malik, Bombay; R. W. Malim and C. E. P. Markby, St. Thomas's; J. H. G. Mason, Middlesex; Ruth Milne, Royal Free; W. A. Mirza, Lucknow; C. J. Morgan, St. Bart.'s; H. C. Muirhead and F. J. Napier, Guy's; L. B. Neel, St. George's; Ethelwyn M. Newham, Royal Free; A. M. Nodine, Middlesex; C. L. Oakley, Univ. Coll.; T. C. Outred, Guy's; M. Owen, Univ. Coll.; C. E. S. Oxley, St. Thomas's; A. P. M. Page, St. Bart.'s; G. H. Pearce, Univ. Coll.; R. B. Peckham, Guy's; A. Phillips and M. Phillips, London; F. E. Pilkington, King's Coll.; A. C. Price, Guy's; Ruth Pumphrey, Univ. Coll.; S. Ramanathan, King's Coll.; E. H. Rink, Guy's; S. L. Robert, Bombay and Birmingham; H. E. W. Roberton, St. Bart.'s; J. M. Robertson, Guy's; Victoria M. Robinson, King's Coll.; Helen E. Rodway, Royal Free; J. D. Rose, Durham; J. Ross, Charing Cross; Ruth Sandeman, Univ. Coll.; F. M. Sandford, St. Thomas's; M. H. Shah, Lahore; Violet R. Sharp and Rosalie Shoenberg, Royal Free; M. Shorvon, King's Coll.; S. Silman, Leeds; H. Singh, Lahore; Margaret Skelton, Univ. Coll.; W. L. Sleight, Bristol; W. M. Smith and B. Southwell, Guy's; N. Stevens, St. Thomas's; Marjorie V. N. Sudds, Royal Free; A. L. Thomas, Guy's; Edith G. N. Thomas, Charing Cross; A. W. Valsey, D. S. Valentine, and J. N. Vasudeva, St. Thomas's; G. M. Vatsalya, Royal Free; W. N. P. Wakeley, King's Coll.; Doris E. C. Walker, Univ. Coll.; Margaret M. White, Royal Free; G. W. Whittall, St. Thomas's; A. B. Williamson, Durham; Mary Wills, Royal Free; H. A. M. Wintle, St. Thomas's; F. S. Winter, St. George's; W. Woolley, Bristol; and C. Wright, Univ. Coll.

Surgery.—R. W. F. Alles and P. B. Ascroft, Middlesex; A. K. Basu, Univ. Coll.; D. A. Beattie, St. Bart.'s; F. R. Beetham, Leeds; D. H. Bolton, St. Thomas's; A. E. Bowling, Leeds; Julia A. Boyd, Royal Free; B. H. Bramwell and R. O. Brooks, Manchester; L. V. O. Brown, Guy's; C. C. Bryson, Middlesex; W. J. Burgess, St. Bart.'s; E. C. Campbell, St. Mary's; F. W. Chippindale, Guy's; S. N. Chopra, Edinburgh; W. F. Church, St. Bart.'s; H. J. Croot, Guy's; H. L. G. Davies, Cardiff and St. Bart.'s; T. J. Davies, Univ. Coll.; C. M. Dell, St. Thomas's; C. G. S. De Silva, Guy's; A. L. Devi, Royal Free; M. B. Dixit, St. Thomas's; P. G. Dowdell and D. G. Evans, Univ. Coll.; R. H. Franklin and A. J. Gibbs, St. Thomas's; Rebecca Goldstein, Univ. Coll.; R. T. S. Goodchild, London; A. H. Grace, St. Bart.'s; B. Halfpenny, Middlesex; H. C. Haige and H. C. Harley, St. Mary's; D. Hay, St. Bart.'s; J. Henry, Leeds; R. Herring, St. Mary's; R. S. Hodge, Univ. Coll.; S. W. Holmes, St. Mary's; Ethel E. Hopper, Charing Cross; G. L. Jones, St. Thomas's; H. J. Knight, St. Mary's; G. F. Langley, Bristol; L. J. Lannaman, St. Bart.'s; Grace Law, King's Coll.; V. J. Lopez, Madras and St. Mary's; S. McDonald, Cambridge and Durham; J. D. McVean, Manchester; B. R. Medlycott, Guy's; H. C. Mehta, Middlesex; P. D. Mottet, Univ. Coll.; F. Murray, London; A. M. Nodine, Middlesex; C. L. Oakley, Univ. Coll.; H. N. Palmer, King's Coll.; G. A. Y. Parker, St. Bart.'s; C. F. L. Patterson, St. George's; D. D. Payne, St. Thomas's; L. D. Pringle Guy's; Ruth Pumphrey, Univ. Coll.; T. P. V. Rao, St. Thomas's; P. V. Reading, Guy's; J. M. Reese, St. Mary's; J. I. Rerrie, St. Bart.'s; Colleen Rice, Charing Cross; B. P. Robinson, Manchester; J. D. Rose, Durham; K. M. Ross, St. Bart.'s; J. F. Sandow, Middlesex; J. D. Scott, St. Bart.'s; J. M. Searle, London; Phyllis F. L. Simon, Royal Free; R. H. B. Snow, St. Thomas's; J. K. Stanger, Durham; F. H. Stevenson, Guy's; G. E. M. Turner, Middlesex; J. N. Vasudeva, Punjab and St. Thomas's; Doris E. C. Walker, Univ. Coll.; S. Weinstein, London; A. J. Whitaker, Univ. Coll.; Margaret M. White, Royal Free; G. W. Whittall, St. Thomas's; E. G. Wilkins, Middlesex; R. C. Williams, St. Thomas's; and T. G. Williams, Middlesex.

Pathology.—A. N. Barker, St. Thomas's; K. Baxter, Manchester; W. L. H. L. Bell, St. George's; S. Bochenek, St. Bart.'s; Kathleen M. Bodkin, Birmingham; P. Brown, London; J. Carlton, Guy's; W. F. Church; St. Bart.'s; D. O. Clark, St. Thomas's; H. Coorland, St. Bart.'s; W. C. Creedee, St. George's; R. E. M. Fawcett, St. Bart.'s; D. R. Goodfellow, Manchester; A. H. Grace, St. Bart.'s; Charlotte Gray, Univ. Coll.; C. J. K. Hamilton, Liverpool; B. Isaac, St. Mary's; H. B. Jackson, Middlesex; R. H. Leaver, St. Bart.'s; J. O. McCarter, Manchester; K. I. Nicholls, Bristol; C. L. Oakley, Univ. Coll.; A. P. M. Page, St. Bart.'s; A. Phillips, London; N. S. Plummer, Guy's; H. Ramsay, Middlesex; Louise Rees, Charing Cross; J. M. Robertson, Guy's; M. W. Robinson, Manchester; T. G. Robinson and B. Southwell; Guy's; T. Standring, King's Coll.; R. Stanley, St. Thomas's; J. G. Stewart, Westminster, K. S. Thompson, London; A. W. Valsey, St. Thomas's; O. T. Wade, Leeds; W. N. P. Wakeley, King's Coll.; A. J. White, Middlesex; G. P. B. Whitwell, Guy's; and Edna M. Wilson, Charing Cross.

OLD EPSOMIAN CLUB.—The annual general meeting of this club will be held at the Hotel Great Central, Marylebone, N.W., at 6.30 P.M. on Thursday, Dec. 12th, and will be followed by the annual dinner at 7.15 for 7.30. The chair will be taken by Brigadier-General G. T. Mair, and all Old Epsomians, whether members of the club or not, are invited to be present on this occasion. Attention is directed to the change of restaurant on this particular occasion.

MEDICO-LEGAL SOCIETY.—A meeting of this Society will be held at 11, Chandos-street, Cavendish-square, W., on Thursday, Nov. 28th, at 8.30 P.M. when Mr. F. Llewellyn Jones, M.P., will read a paper on the League of Nations and the International Control of Dangerous Drugs.

As already announced, the annual dinner will be held at the Holborn Restaurant, London, W.C., at 7.15 P.M., on Friday, Dec. 13th, with the President, Lord Riddell, in the chair.

Royal College of Physicians of Edinburgh.—A quarterly meeting of the College was held on Nov. 5th with Dr. R. A. Fleming, the President, in the chair.

Dr. William Thomson Munro was introduced and took his seat as a Fellow. Dr. Roy Mackenzie Stewart and Dr. William Malcolm McAlister were elected to the Fellowship.

The Hill Pattison-Struthers Bursary in Anatomy and Physiology was awarded to James Alexander Crawford, and the Hill Pattison-Struthers Bursary in Clinical Medicine to Dr. William Veitch Anderson. The Wood Bursary was awarded to John Macgill Drover.

Royal Faculty of Physicians and Surgeons of Glasgow.—At the annual meeting on Nov. 4th Dr. John F. Fergus was elected President in succession to Mr. G. H. Edington. The other office-bearers appointed are:—Visitor: Mr. R. Barclay Ness. Hon. treasurer: Dr. J. H. Macdonald. Hon. librarian: Dr. E. H. L. Oliphant. The representative on the General Medical Council is Mr. Edington, and the councillors are Prof. J. M. Munro Kerr, Mr. Thomas Kay, Mr. John Patrick, Dr. R. M. Buchanan, Mr. J. Galbraith Connal, Prof. C. C. Douglas, Dr. John Gracie, Prof. Andrew Allison, Dr. J. Souttar McKendrick, and Mr. W. Ferguson Mackenzie. It may be noted that Dr. J. F. Fergus's father and his brother, the late Mr. Freeland Fergus, served as Presidents of the Faculty.

In leaving office as President Mr. Edington presented to the Faculty an interesting memorial of their founder, Mr. Peter Lowe.

The gift took the form of the first edition of Lowe's "Whole Course of Chirurgerie," published by Thomas Purfoot, London, in 1597. The library already contained copies of the second, third, and fourth editions of Lowe's "Chirurgerie," and, with this presentation, it now possesses a complete set of all the works and editions of Peter Lowe.

Copies of the first edition of this book are extremely rare. One is known to be in the Radcliffe Library, Oxford; another was in the library of the Royal Medical and Chirurgical Society of London; and a third copy is in the possession of the Royal College of Physicians of Edinburgh. The destination of a fourth copy, sold in London in October, 1924, for £120, is unknown. The copy presented to the Faculty Library by Mr. Edington is slightly imperfect, lacking some few of the end pages. Otherwise it is in very good condition.

The Faculty accepted the interesting gift with enthusiasm, and cordially thanked the donor.

Glasgow University Club of London.—This club will dine at the Trocadero Restaurant, Piccadilly-circus, on Friday, Nov. 29th, with Prof. F. O. Bower, F.R.S., President-elect of the British Association, in the chair, and Sir Donald MacAlister, Chancellor of the University, as the principal guest. Any Glasgow University men who, though not members of the club, desire to be present are requested to communicate with the hon. secretaries, 62, Harley House, N.W. 1.

Decorations and Distinctions.—The King has given Royal licence and authority to Dr. Herbert Chavasse Squires to wear the Insignia of the Order of the Nile (Third Class) conferred upon him by the King of Egypt in recognition of valuable services rendered by him. Dr. D. J. Mackintosh, C.B., M.V.O., has been made a Deputy Lieutenant of the County and City of Glasgow. Dr. James Cran has been appointed an Unofficial Member of the Legislative Council of the Colony of British Honduras.

Joint Tuberculosis Council.— A post-graduate course in relation to tuberculosis is to be held in the X Ray Department of the Hospital for Diseases of the Chest, Brompton, London, S.W., from Monday to Saturday, Nov. 25th–30th, conducted by Dr. Stanley Melville and members of the staff. The course will consist largely of demonstrations on screening, with lectures on technique, the surgical aspect of tuberculosis and dental radiography. Arrangements are being made for refresher work in out-patient department or wards, and a visit to a factory to see the latest things in X ray apparatus. Application to the hon. sec. of the Council at 1, Gordon-square, London, W.C. 1.

College of Physicians of Philadelphia: *Alvarenga Prize.*—The next award of this prize, amounting to about three hundred dollars, will be made on July 14th, 1930. Essays upon any subject in medicine will be considered provided that they have not appeared in print in any form, and have not been presented elsewhere in competition for a prize. They must be in prescribed form and must be received by the secretary of the College by May 1st. The Alvarenga prize for 1929 has been awarded to Dr. George M. Darrance, of Philadelphia, for an essay on Congenital Insufficiency of the Palate.

Hospital Costs at Nottingham.—During the *first six months of the present year the average weekly cost* of each in-patient at Nottingham General Hospital was £2 14*s.* 10½*d.*, and the total cost per patient £7 8*s.* 5*d.* The average cost per bed occupied amounted to £71 6*s.* 0½*d.*; the average stay was 18·8 days.

New Hospital at Nottingham.—On Nov. 5th Princess Helena Victoria visited Nottingham and opened the new women's hospital, which has cost about £40,000, and will take the place of two older and smaller institutions. Accommodation is provided for 60 beds, and the new wing, which is shortly to be undertaken at a cost of about £12,000, will provide another 40 beds. The hospital has been opened free of debt.

Voluntary Hospital Patients in Poor-law Infirmaries.—The governors of the Royal Hospital, Wolverhampton, have arranged with the Wolverhampton board of guardians that patients recommended by its honorary staff shall, in given circumstances, be received for treatment in the New Cross Poor-law Hospital. This course has become desirable owing to the inability of the Royal Hospital to meet pressing needs. The guardians will be paid an agreed sum where patients or their dependents have contributed for a reasonable time to the funds of Wolverhampton Hospital.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Nov. 19th.—5.30 P.M., General Meeting of Fellows. *Ballot for election to the Fellowship.* 8 P.M., Pathology. Communications:—Dr. G. S. Wilson: The Isolation of *Brucella abortus* from a Human case of Undulant Fever. Dr. C. R. Harington: The Chemistry of the Thyroid. Demonstrations:—Dr. W. G. Barnard: Three Specimens of Ependymoma. Fellows and Members of other sections are cordially invited to attend this meeting.

Thursday.—5 P.M., Dermatology (Cases at 4 P.M.). Dr. H. W. Barber: Case for Diagnosis. Dr. H. W. Barber: ? Lupus Erythematosus of the Oral Mucous Membrane. Dr. G. B. Dowling: Norwegian Scabies: Pityriasis Lichenoides et Varioliformis Acuta. Dr. W. J. O'Donovan: Lichen Spinulosus. Dr. A. C. Roxburgh: Pityriasis Lichenoides et Varioliformis Acuta (with section).—Other cases will be shown.—Annual Dinner of the Society. May Fair Hotel, Berkeley-square, London, W., at 7.30 for 8 P.M.

Friday.—5 P.M., Disease in Children (Cases at 4.30 P.M.). Cases will be shown. 8 P.M., Epidemiology and Tropical Diseases. Special Discussion on Brucella Infections in Man and Animals. Openers: Dr. W. Dalrymple-Champneys (Epidemiology), Dr. J. T. Duncan (Tropical). Other speakers will also take part.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Thursday, Nov. 21st.—8.15 P.M. A Laboratory Meeting will be held at the London School of Hygiene and Tropical Medicine, Keppel-street, Gower-street, when the following amongst others will give Demonstrations: Drs. Andrew Balfour, W. Broughton Alcock, C. A. Hoare, E. Hindle and A. C. Stevenson, Colonel S. P. James, Messrs. H. S. Leeson, M. E. MacGregor, J. F. Marshall and J. Staley, Drs. A. Robertson, J. W. Scharff, A. L. Sheather and A. C. Stevenson, H. M. Shelley, Miss E. Sikes, Prof. Warrington Yorke, Dr. C. M. Wenyon, V. B. Wigglesworth.

CHELSEA CLINICAL SOCIETY.

Tuesday, Nov. 19th.—7.30 P.M., Dinner at Hotel Rembrant, Thurloe-place, S.W., followed by discussion on Treatment of Climacteric. Opened by Dr. F. J. McCann.

LONDON CLINICAL SOCIETY.

Tuesday, Nov. 19th.—8.45 P.M. (at the London Temperance Hospital), Meeting. Cases at 8.30 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Nov. 18th., to Saturday, Nov. 23rd.—Medical Society of London, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., lecture by Mr. A. E. Mortimer Woolf: Hæmorrhoids. No fee. Two lectures, especially suitable for M.R.C.P. candidates.—Tues., 8.30 P.M., Dr. Langdon Brown: Recent Advances in Endocrinology. Fri., 8.30 P.M., Sir William Willcox: Some Points in Connexion with the Toxic Effects of Lead, Arsenic, Morphine, Cocaine.—Prince of Wales's General Hospital, Tottenham, N. Mon., 2.15 P.M., Ward Round by Dr. A. J. Whiting. No fee.—Royal Eye Hospital, Southwark, S.E. Wed., 3 P.M., demonstration by Mr. A. D. Griffith. No fee.—London Lock Hospital, 91, Dean-street, W. Post-graduate course in venereal disease. Daily, every afternoon and evening, for two weeks.—Royal National Orthopædic Hospital, 234, Great Portland-street, W. Intensive course for two weeks.—West End Hospital for Nervous Diseases, 73, Welbeck-street, W. Lecture-demonstrations, illustrated by cases, daily at 5 P.M. Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

Monday, Nov. 18th.—10 A.M., Dr Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Wards.

Tuesday.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw, Medical Out-patients. 2.30 P.M., *Sir Henry Simson: Gynæcological Operations.*

Wednesday.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. Dr. Scott Pinchin: Medical Out-patients.

Thursday.—11.30 A.M., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

Friday.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Shaw: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.

Saturday.—9 A.M., Mr. Vlasto: Throat, Nose and Ear Operations. 9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Children's Department.

Daily, 10 A.M. to 5 P.M., Medical, Surgical and Special Out-patients, Operations, Ward Visits, Anæsthetic Courses.

SOUTH-WEST LONDON POST-GRADUATE SOCIETY, St. James's Hospital, Ouseley-road, Balham, S.W.

Wednesday, Nov. 20th.—4 P.M., Mr. Norman Haire: Contraception Technique.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday, Nov. 18th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

Tuesday.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

Wednesday.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

Thursday.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics, Operations.

Friday.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations. 4.30 P.M.: Demonstration on Practical Neurology by Dr. L. R. Yealland.

NATIONAL HOSPITAL, Queen-square, W.C.

Monday, Nov. 18th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Collier: Muscular Atrophies.

Tuesday.—2 P.M., Dr. Walshe: Out-patient Clinic. —3.30 P.M., Mr. Armour: Surgery of Compression Paraplegia.

Thursday.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Walshe: Vascular Lesions of Nervous System.

Friday.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: Clinical Lecture.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

Wednesday, Nov. 20th.—4.30 P.M., Mr. Claude Mills: Some Interesting Urological Cases.

KING'S COLLEGE FOR HOUSEHOLD AND SOCIAL SCIENCE, Campden Hill-road, W.

Friday, Nov. 22nd.—5 P.M., Prof. V. H. Mottram: Human Nutrition. (Last of six lectures.)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Monday, Nov. 18th.—5 P.M., Prof. Leonard Hill: Clothing and Climate.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL Gray's Inn-road.

Friday, Nov. 22nd.—4 P.M., Mr. J. D. McLaggan: The Treatment of Chronic Suppurative Otitis Media.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.

Thursday, Nov. 21st.—6 P.M., Mr. John Everidge: Hæmaturia: Its Diagnosis and Significance.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

Tuesday, Nov. 19th.—3.15 P.M., Mr. W. B. Gabriel: The Treatment of Acute Suppuration.

BRITISH SCIENCE GUILD.

Tuesday, Nov. 19th.—4.30 P.M. (in the Goldsmiths' Hall, Foster-lane, E.C.), Sir Walter M. Fletcher: Medical Research: the Tree and the Fruit.

PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, W.

Friday, Nov. 22nd.—6 P.M. (at the Medical Society of London, 11, Chandos-street, W.), Dr. E. G. Howe: Infant, Youthful, Adolescent, and Adult Life.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

Wednesday, Nov. 20th.—4 P.M., Mr. Malcolm Donaldson: Early Diagnosis and Treatment of Malignant Disease.

CHADWICK PUBLIC LECTURES.

Friday, Nov. 22nd.—5.15 P.M. (at the Royal Society of Arts, John-street, Adelphi), Prof. A. E. Boycott: The Causes of Cancer.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

Tuesday, Nov. 19.—5 P.M., Dr. J. A. Drake: Leprosy.

Thursday.—5 P.M., Dr. A. Whitfield: Tuberculosis Cutis (1).

ANCOATS HOSPITAL, Mill-street, Manchester.

Thursday, Nov. 21st.—4.15 P.M., Mr. P. McEvedy: Treatment of Hæmorrhoids.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

Friday, Nov. 22nd.—3.30 P.M., Mr. Mackie: Ophthalmic States related to Gastro-Intestinal Disorders.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, Nov. 19.—4.15 P.M., Mr. W. R. Douglas: Some Recent Advances in the Surgery of Cancer.

Friday.—4.15 P.M., Dr. R. Ellis: How the Electrocardiograph helps in Diagnosis and Treatment.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

Wednesday, Nov. 20th.—4.15 P.M. (in the Western Infirmary), Mr. Roy F. Young: Demonstration of Surgical Cases.

Appointments.

Bell, J. H., M.B., Ch.B. Edin., has been appointed Casualty House Surgeon at the Salford Royal Hospital.

Duggan, Norman, M.B., Ch.B. Manch., F.R.C.S. Eng., Honorary Surgeon to Worcester General Infirmary.

Gleave, H. H., M.B., Ch.B. Leeds., Senior Lecturer in Pathology in the University of Liverpool.

Lindsay, Elizabeth M., M.B., Ch.B. Edin., Medical Officer of the Parish of Creich and Superintendent of Swordale Institution, Bonar-Bridge, Scotland.

Paton, R. Y., M.B., B.Chir. Camb., Assistant Surgeon, Royal National Orthopædic Hospital.

Roberts, J. T. C., M.B., Ch.B. Liverp., Assistant Medical Officer of Health, Lewisham.

Saunders, M. J., L.R.C.P. & S.I., *Certifying Surgeon* under the Factory and Workshop Acts for the Portland District of Dorset.

Struthers, J. A., M.R.C.P. Lond., D.P.H., Physician to the Willesden General Hospital.

Vacancies.

For further information refer to the advertisement columns.

Altrincham General Hospital.—H.S. At rate of £125.

Barnsley, Beckett Hospital and Dispensary.—H.P. £140.

Barry Surgical Hospital.—H.S. At rate of £200.

Birmingham City Babies' Hospital.—Res. M.O. At rate of £150.

Birmingham, Dudley-road Hospital.—Surgeon. £700.

Birmingham Royal Cripples Hospital.—H.S. At rate of £200.

Blackburn and East Lancashire Royal Infirmary.—Fourth H.S. £130.

Bolton Infirmary and Dispensary.—H.S. £150. Also Asst. H.S. £100.

Brighton, Royal Sussex County Hospital.—Hon. Surg. Clin. Asst. Also H.S. and Cas. H.S. £150 and £120 respectively.

Bristol, Stoke Park Colony.—Director of Medical Services. £1200.

Brookfield Orthopædic Hospital, Hale End, Woodford Green.—Anæsthetist. 1 guinea per attendance.

Cardiff, King Edward VII. Welsh National Memorial Association.—Area Asst. Tuber. Physician. £600.

Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100. Also Registrar. £50.

Chester Royal Infirmary.—Two H.S.'s. Each £150.

City of London Hospital for Diseases of Heart, &c., Victoria Park, E.—Res. M.O. £250. Also H.P. At rate of £100.

City of London Maternity Hospital, City-road, E.C.—Asst. Res. M.O. At rate of £80.

Colonial Medical Service.—M.O.'S. East Africa, £600. Malaya, $500 per month.

Dreadnought Hospital, Greenwich.—H.P. and H.S. At rate of £110.

Ealing Borough.—Asst. M.O.H. £600.

East London Hospital for Children, &c., Shadwell, E.—Surgeon to Nose, Throat, and Ear Dept.

Epsom, Surrey, The Manor.—Res. Med. Supt. £671.

Essex County Sanatorium, Black Notley, near Braintree.—Res. M.O. £650.

Evelina Hospital for Children, Southwark, S.E.—Hon. Surgeon to Out-Patients. Also H.S. At rate of £120.

Glasgow, Royal Hospital for Sick Children.—Two H.S.'s.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P. At rate of £135.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—Cas. M.O. and Cas. Surg. O. Each at rate of £100.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. and H.P. Each at rate of £100. Also Part-Time Jun. Cas. O. At rate of £150.

Ipswich, Heathfields Infirmary, &c.—Asst. Res. M.O. £250.

Leeds Jewish Herzl-Moser Hospital.—Res. M.O. £100.

Lincoln, Bracebridge Mental Hospital.—Third Asst. M.O. £350.

Manchester, Salford Royal Hospital.—H.P. At rate of £125.

Metropolitan Ear, Nose and Throat Hospital, Fitzroy-square, W.—H.S. £150.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Sen. Res. M.O. Also Jun. Res. M.O. At rate of £140 and £100 respectively.

Mothers' Hospital, Clapton, E.—Hon. Asst. Obstet. S.
Nairobi Municipal Council.—M.O.H. £1100.
National Hospital, Queen-square, W.C.—Res. M.O. £200.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Two Hon. Asst. S.'s.
Northwood, Mount Vernon Hospital.—H.S. for Cancer Section. £200.
Perth Infirmary.—Jun. H.S. £75.
Plymouth, South Devon and East Cornwall Hospital.—Res. Surg.O. Also H.S. At rate of £150 and £100 respectively.
Prince of Wales's General Hospital, Tottenham, N.—Hon. Clin. Assts.
Rochdale Infirmary and Dispensary.—Jun. H.S. £175.
Rochford, Poor-law Hospital.—Jun. Asst. M.O. At rate of £225.
Royal College of St. Katharine, Poplar, E., Maternity and Child Welfare Centre.—Asst. M.O. £1 11s. 6d. per session.
Royal College of Surgeons of England.—Examiner in Dental Surgery.
Royal Free Hospital, Gray's Inn-road, W.C.—H.S.'s, H.P.'s, &c. Each £150. Second H.P. and Obstet. Dist. Asst. £100. Surg. Reg. £200. Half-time Gynæcological Reg. and Med. Reg. Each £100.
St. Mary's Hospital, W.—Med. Reg. to Out-patients. £200.
St. Thomas's Hospital, S.E.—Two Surg. Reg.'s. Also Med. Reg. for Children's Dept. Each £250.
Sheffield, Jessop Hospital for Women.—Asst. H.S. At rate of £100.
South London Hospital for Women, South Side, Clapham Common, S.W.—Clin. Assts.
Southampton, Royal South Hants and Southampton Hospital.—Asst. H.S. and Res. Anæsthetist. At rate of £140.
South Eastern Hospital for Children, Sydenham, S.E.—Res. M.O. At rate of £75.
Stamford, Rutland and General Infirmary.—H.S. At rate of £200–£250.
Surrey County Council.—Asst. M.O. £600.
Tilbury Hospital, Essex.—Med. Supt. £250. Also H.S. At rate of £150.
University College Hospital, Gower-street, W.C.—Hon. Anæs.
Warrington Infirmary and Dispensary.—Jun. H.S. £175.
West London Hospital, Hammersmith-road, W.—H.P., H.S. Aural and Ophth. H.S. and Asst. Cas. O. Each at rate of £100. Also Asst. Surgeon Dentist.
Windermere, Ethel Hedley Hospital for Crippled Children.—Res. H.S. At rate of £150.
Windsor, King Edward VII. Hospital.—Two H.S.'s. Each £100.
Worcester City Council.—M.O.H. £900.
The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Shefford (Beds), Eckington (Derbyshire), Wadebridge (Cornwall), Calvert (Bucks), and Llanfyllin (Montgomery).

Births, Marriages, and Deaths.

BIRTHS.

CRAIG.—On Nov. 6th, at Cheadle Hulme, the wife of Dr. Nicholas Craig, of a daughter.
FLOWER.—On Nov. 7th, the wife of Dr. Norman Flower, Yeovil, of a son.
HOLMES.—On Nov. 4th, at Hoghton-street, Southport, the wife of John Holmes, M.B., M.R.C.P., of a son.
HORSBURGH.—On Nov. 3rd, at Lyndhurst, Manor Court-road, Nuneaton, the wife of Dr. P. G. Horsburgh, of a son.

MARRIAGES.

RICHARDS—HODGKINSON.—On Oct. 5th, at Shiraz, Persia the Rev. J. R. Richards to Katharine Mary Hodgkinson, M.B., B.Ch., only daughter of Mr. and Mrs. W. E. Hodgkinson, Inglewood St. Michael's, Tenterden, Kent.

DEATHS.

FALKINER.—On Oct. 30th, at Dublin, Ninian McIntire Falkiner, M.D., F.R.C.P.I., late of Tyone, Healthfield-road, Terenure, County Dublin.
GILES.—On Nov. 4th, at Floraire, Torquay, Frederick William Giles, M.R.C.S., M.B.
GREENWOOD.—On Nov. 7th, at Hanover House, Regent's Park, Edwin Climson Greenwood, O.B.E., M.R.C.S., L.R.C.P., Medical Superintendent to St. John and Elizabeth Hospital.
SEALEY.—On Nov. 3rd, at Arundel-road, Tunbridge Wells, Francis Marmaduke Sealey, J.P., M.R.C.S., L.R.C.P., in his 71st year.
SWINHOE.—On Nov. 10th, suddenly, at The Close, Swindon, George Rodway Swinhoe, M.R.C.S., aged 61.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices o Births, Marriages, and Deaths.

BRITISH HOSPITALS ASSOCIATION.—This association has just been registered as a company limited by guarantee, not having a share capital, to acquire the undertaking and such of the assets and liabilities of the British Hospitals Association as may lawfully be acquired. The management is vested in a Council, the first members of which include Sir Arthur Stanley, Lord Knutsford, and Lord Stanmore. The hon. sec. is Mr. R. H. P. Orde, and the registered office, 32, Gordon-square, W.C.

Notes, Comments, and Abstracts.

RACIAL STUDY IN SCOTLAND.

IN a presidential address to the Aberdeen Medico-Chirurgical Society on Oct. 31st Prof. Alexander Low pointed out that while undoubtedly hygiene and better nutrition were important factors making for better health, attention should also be paid to racial inheritance. In Scotland much less displacement of population by invasion had taken place than was commonly supposed, and racial types could be traced in varying proportions in different parts of the modern population. Thus the study of racial strain was a matter of practical importance.

The present inhabitants of Scotland, said Prof. Low, included a primitive substratum from palæolithic days, together with representatives from the Nordic, Mediterranean and Alpine races. The tall, fair, long-headed Nordic was more suited to rural than urban conditions, and there was evidence (E. G. Bowen) that in towns he was especially liable to diseases, such as tuberculosis, when depressed into industrial poverty. The broad-headed Alpine was an element that entered largely into the make-up of the people in the north-east of Scotland and was characterised by patience, thrift, and caution. The short, dark, long-headed Mediterranean type was found in the poorer quarters of the large cities—for example, in Glasgow—where they seemed to resist disease caused by overcrowding. In Glasgow the infant mortality had shown a uniform fall, and it was argued that the large proportion of immigrant Irish and Jews had added vigour to the native stock; but the suggestion was put forward that in Glasgow there was a large Mediterranean element in the population and that this dark strain encountered the adverse conditions of city life more successfully than the Nordic.

In attempting to record developmental changes and their correlation, if any, with different race types, Prof. Low had come to the conclusion that growth-promoting internal stimuli differed in different races. Some seven years ago with the coöperation of Prof. R. G. McKerron at the Aberdeen Maternity Hospital and Dr. James A. Stephen of the Child Welfare Centre, he had begun to follow up growth in infants and had been led to study how far and in what way racial type affected development.

Knowledge of the physical characteristics of the preschool child had previously been based on single measurements of groups of infants, and there was thus no way of estimating the degree of variation in the same child from year to year. To follow the growth of individual children was slow and laborious, and though for the past seven years many had been under observation the work was still far from complete. About 1000 infants had been examined at birth and so far as possible re-examined yearly.

In the Aberdeen infants examined the average birthweight of the male infant was 3458 g. (7·625 lb.) and of the female 3444 g. (7·59 lb.). Thus there was little difference between the average weights of the two sexes, but infants born in Aberdeen were from six to eight ounces heavier at birth than those born in other towns in Great Britain. The average birth-length of males was 49·2 cm. (19·3 inches) and of females 48·7 cm. (19·18 inches), about one inch less than the usually accepted average birth-length. The average weight of the same group of infants at 12 months was 9240 g. (20·37 lb.) for males and 8306 g. (18·312 lb.) for females, and the average lengths at 12 months for males was 72·0 cm. (28⅜ inches) and females 70·1 cm. (27⅝ inches).

THE INDICTMENT OF CERTAIN INDIAN CUSTOMS.

OF the large crop of books and newspaper articles which followed the publication in 1927 of "Mother India" the great majority have already been consigned to oblivion, but some of them came from sources which it is impossible to disregard, and Mr. Field has performed a useful service in summarising the case for and against Miss Mayo's indictment of some Indian customs.[1] He is particularly well qualified for this task, since he was at one time working in close association with Miss Mayo, and has had access to documents in her possession.

In such a mass of evidence as was accumulated by Miss Mayo it was inevitable that some inaccuracies should occur, but with remarkably few exceptions her statements are substantiated. This, indeed, one would expect from her previous record which is detailed by Mr. Field and shows that "Mother India" was by no means her first adventure in the field of social research. Her book met with a hostile reception from the Indian press as a whole, but criticisms were not all unfavourable. It is a curious fact that the most striking evidence in favour of Miss Mayo's work comes indirectly from the great Hindu mystic Mohandas Karamchand Gandhi himself, although in an article in his own paper he attacked it with vigour. The Hindu customs arraigned by Miss Mayo are the very ones which Mr. Gandhi himself deplores

---

[1] After Mother India. By Harry H. Field. London: Jonathan Cape. 1929. Pp. 299. 7s. 6d.

It has been said that Miss Mayo's book is untrue to facts and unjust to the people of India. The book certainly came as a shock to many European friends of India, as well as to Indians themselves, and it may fairly be argued that to enter the country through a temple of Kali, and to concentrate on social abuses throughout, is not to see it whole. To this Miss Mayo replies that she does not claim to give a complete picture of Indian life, nor pretend to dwell upon the virtues and accomplishments of the Indian people. The great question, after all, is what are the results of Miss Mayo's outspoken criticisms. Some of these are already not far to seek, although, as Mr. Field says, it will probably be decades before a comprehensive estimate can be made. For the present, however, they are sufficiently well summed up in a paragraph from the *Statesman* (Calcutta) of April 11th, 1929, which runs as follows :—

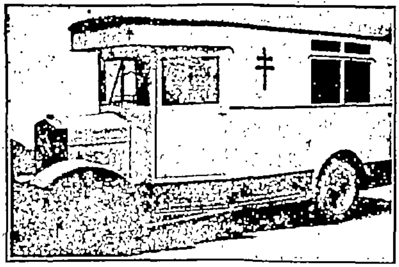
> "We believe that with all its faults of over-statement and exaggeration Miss Mayo's first book ("Mother India") did definite and traceable service. It provoked a vast torrent of indignation, but it gave strength to all the reformers who are endeavouring to change conditions in India. It shocked people out of complacency. Indians saw how they were presented to western eyes. . . . Nobody could longer blind himself to the fact that child marriage, the prevention of the remarriage of widows, the treatment of the outcaste and cruelty to animals outraged the western peoples. . . . Reform must come from within. Happily, there is evidence on all hands that Indian opinion is changing and that the new movement is finding leaders. When it has triumphed, India itself will be able to take a more charitable view of those who first uttered the thoughts of the West."

New legislation on the subject of the age of marriage has recently borne testimony to the influence which "Mother India" has brought to bear on social problems, for it can hardly be contested that the wave of feeling on this question was partly due to Miss Mayo's book.

AN ANTI-TUBERCULOSIS MOTOR VAN.

THE Fiat Motor Car Company of Turin has presented to the Red Cross Society at Rome a travelling dispensary equipped with the latest appliances of medical science for the campaign against tuberculosis. It is intended that vehicles of this type should carry the campaign into rural districts and remote mountain villages devoid of doctors and hospitals. The running cost is said to be low, for about 20 visits can be made in a radius of 20 miles or so during the day at a cost of about two shillings per consultation. The equipment, supplied by the Itan Company of Milan, comprises a complete X ray installation, microscope table, apparatus for analysis and sterilisation, as well as a projector to illustrate popular lectures on health and prophylaxis. The whole is mounted on an all-metal body motor chassis, where it can be used with the same efficiency and safety as in hospital. To avoid the diffusion of radiation, the tube is properly protected and an "antix" rubber protector screens off secondary rays. All parts of the installation which come into contact with the patient are covered with easily changeable or disinfectable paper and celluloid screens. Apparatus carrying high tension current is insulated from surrounding objects, and all metal parts are earthed. The generator, which is outside the dispensary, alongside the chauffeur, furnishes sufficient current for an X ray photograph of the thorax to be taken in a fraction of a second. The stores for photographic plates and slides are fitted with safety locks, so that should the controller forget to close them an electrical device rectifies the omission. During an X ray examination the dispensary is lit by a special filtered ray lamp which, while not interfering with the clearness of the image on the screen, does not leave the patient in the dark. The X ray apparatus can be carried into the patient's bedroom in case he is unable to leave the house. We are told that inquiries for motor vehicles of this type have been received from America, Belgium, and especially the Balkan countries.

FIG. 1.



The motor van bearing the combined red-cross anti-tuberculosis symbol.

FIG. 2.

The interior of the van with a consultation in progress.

A HOSPITAL FANCY.

AN account of the hospital of the future, as imagined by one who evidently derides many scientific "improvements" of to-day, is amusingly provided in the current number of the *St. George's Hospital Gazette*. The leading member of the staff is the "head electrical expert and master of mechanics," known as H. E. Next to him come in order electroradiological therapeutists, biochemicosanguinologists, uroproctologists, proctourologists, aurorhinists, rhinoaurists, bacteriopathological experts, electromechanicians, one physician and one surgeon! There is no dentist on the staff, for no patient is admitted to the hospital who still retains any teeth, because of the possible infection from these. The routine preparation of the stranger who desires to visit the hospital takes seven days, so thoroughly imbued are the authorities of the institution with the principles of scientific preventive medicine. Inside the hospital all use of the feet is abandoned, transport being entirely by electric propulsion or by aeronautics. In the operating theatre the table suddenly appeared under no apparent motive power and rolled itself into the middle of the theatre. A remarkable rumble heralded the arrival of the unconscious patient who was wafted on to the operating table. This, worked from without, executed a remarkable series of convulsive jerks till the patient was in the position required by the uroproctologist about to operate. He glided in on and was removed from a small electric trolley and was suspended at the convenient height in proximity with the patient's exposed anal area. This was rapidly prepared by aero-sterilisation, and the accompanying din put a premature end to the observer's visit. The imaginary hospital appears to be placed in America, but the writer's attitude and initials, J. B., are suggestive of John Bull.

THE PREVENTIVE MEDICINE OF DIVORCE.

WHILE some are disposed to believe in haste that marriage is an outgrown institution, others, equally aware of the growing divorce lists, are sure that sick marriages may often be cured and still more often the sickness be prevented. Physicians in many lands have been offering their services in the solution of this human and social problem. In June last the French Congress of Legal Medicine discussed the value of the medical pre-nuptial certificate.[1] The object envisaged was not merely to detect venereal disease but also other forms of contagious disease, hereditary defects, and early stages of such diseases as tuberculosis which are liable to make more rapid progress under the strain of marriage and pregnancy. The objections raised to the institution of this certificate were directed only against its compulsory features and not against the essential proposal that medical examination before marriage is to be encouraged. In Germany the Berlin-Steglitz section of the National Association of Red Cross Women has established a "matrimonial consultation service" to help married couples to overcome or to avoid the difficulties that arise in the course of married life.[2] Although this service is directed by a psychologist who is not a graduate in medicine, it is explained that the service works in close coöperation with the public health service. At the third international congress of the World League for Sexual Reform, held last month in London, a paper by Dr. Abraham Stone, of New York, was read in absentia. The writer pointed out that there is even a statistical correlation between premarital examination and happiness in the future married life. The importance of this procedure is again emphasised in a paper published still more recently.[3] "The preventive medicine of divorce," writes Dr. Earp, "consists in premarital advice not only on how to choose, but also on how to live with the chosen mate; supplemented by premarital medical examination, designed to exclude impossible partnerships and to safeguard others from unnecessary difficulties and pain."

"ELECTRICAL SECURITY."

THE enormous increase in the use of electricity throughout the country, not only for lighting but for other services, implies a higher standard of safety in electrical installations. The wiring which has proved adequate for the lighting of a house may fail disastrously when required to carry the current needed for electric fires; in particular electro-medical apparatus of all kinds require a high standard of workmanship not only in the instrument but also in the supply feeding it. The Electrical Contractors' Association have issued a small booklet under the above title which deals with these and kindred points. The different types of installation are explained with the advantages, limitations, and relative cost of each; the makeshifts of careless wiring are tabulated and types of satisfactory fittings are described and illustrated.

The booklet has practical value, not only for the electrical engineer, but for every user of electrical power. The question arises, however, whether the high standard of safety demanded here is practicable. Most of the recommendations are based on regulations drawn up by the Institute of Electrical Engineers, and in the main they form an invaluable standard. When such schemes are drawn up the necessity of avoiding risks is felt so strongly that often an unreasonable margin of safety is demanded. Later it is found in practice that it is perfectly safe to ignore some particular rule and trust to experience, with the inevitable result that a rule which can be broken with impunity brings the whole scheme into contempt. Thus a rule originally framed to ensure perfect safety may have exactly the opposite effect in practice.

As an example, take the condemnation of ordinary twin flex which, according to this booklet, should be confined to stationary lights. The use of this form of wire for taking current to all sorts of portable apparatus is nowadays so universal that it will need more evidence than is given here of the dangers involved before the public is likely to abandon its use. The alternative specified consists of three flexible wires in an outer cover. It is difficult to see the superiority of such a cable except in the matter of kinking, whilst the increase in cost would be enormous.

MOTHERCRAFT.

MEDICAL men and women, even if they are not in practice are apt to be called into consultation on matters of mothercraft in and out of season, though their advice is not always accepted. Dr. L. G. Housden[4] has anticipated many of the questions usually asked, and suggests to his readers "if your friends worry you excessively, give them this book to read." He opens his introductory letter with the disarming statement: "This is not a medical book, but a series of short chapters dealing in a practical manner with the various problems of babyhood." The teaching is, in fact, quite elementary, and could be appreciated by young mothers of no great educational attainment, though some of the recommendations are hardly within the reach of poorer sections of the community. Dr. Housden is a relentless advocate of breast-feeding, but the faithful disciple of Sir Truby King will read with surprise the suggestions that for the first few days of life a night-feed may be given; that mackintosh knickers are unobjectionable, and that half a teaspoonful of water between feeds is the most that a baby may receive, and that only in abnormally hot weather. The author points out the absurdity of believing that new-born infants are in need of either aperients or operations; the baby who passes irregular motions and the tongue-tied baby will both achieve normality with the exercise of patience, and circumcision should only be performed where there is some real difficulty in passing water. The aim of the book is to induce a sense of confidence in the mothers who read it, and many minor causes of alarm are robbed of their terror by straightforward analysis and explanation. Perhaps the best chapter is that on character training, which emphasises the importance of the personal as well as the material environment.

ANOTHER LOCAL ANÆSTHETIC.

A NEW analgesic called "perkain" receives warm commendation from those who have tried it both experimentally and in clinical practice.[1] Unlike cocaine, tutocaine, and other local anæsthetics, it is not a benzoamino-alcohol product, but is a complicated derivative of the quinoline group. It consists of colourless crystals which dissolve easily in water with an alkaline reaction. The solution can be sterilised by boiling, and can be used in conjunction with adrenalin. It is more slowly absorbed than cocaine, and poisonous effects are therefore less easily brought about and are in many cases said to be far less. It is stated that there is no likelihood of acquiring a drug habit from perkain. It has given complete satisfaction as a surface analgesic on mucous membranes, and when injected into the bladder for cystoscopy. For this purpose 30 to 40 c.cm. of a 1 in 1000 solution was used. As a spinal analgesic for lumbar injection it has not given good results in seven out of ten instances in which it was employed. So far the largest series of cases reported of the use of perkain for local analgesia is 200. One case of collapse is reported after the use of a solution much stronger than 1 in 1000.

LA CURE D'AIR.

IT is still not an uncommon practice for the physic to prescribe a sea voyage, and in the last century a to the antipodes was popular as a therapeutic meas But the physician's armoury changes with the times, and D Charles L. Julliot may be right when he suggests[2] that aeroplane will eventually replace the ship as a therap mode of locomotion. The use of aviation for the eva tion of wounded in time of war or the transport of si time of peace is already well known, but it is in Ce Europe that the air is being exploited as a form of t ment. According to a well-known German medical m a young girl of 14 has been cured of a persistent cou a trip in an aeroplane, while a neurasthenic patient obtained a renewed zest for life. Nor is there any surprising in this, for the altitude, the open air, the sp and an occasional nose-dive are all stimulating experie The review sagely warns the enthusiast from subm cases of acute mania or of advanced heart disease t aerial cure, but for many other disorders it is thou flying may replace visits to the Alps or other places of altitude. Much is already known of the physiol changes which take place at high altitudes, and it is ceivable that such knowledge may be translated in of therapeutic value: air trips of graduated heigh time for definite disorders, prolonged treatment in a c balloon for chronic cases. But Dr. Julliot is a d law, not of medicine, and he does general recommendation to the spec

Bradshaw Lecture

ON THE

SURGERY OF THE GALL-BLADDER AND BILE-DUCTS.

A REVIEW.

Delivered before the Royal College of Surgeons of England on Nov. 14th, 1929,

By R. P. ROWLANDS, O.B.E., M.S.Lond.,
FELLOW AND COUNCILLOR OF THE COLLEGE; SURGEON TO GUY'S HOSPITAL.

The surgery of the gall-bladder and bile-ducts is only about fifty years old. Lister's[1] epoch-making discoveries had paved the way for it some twelve years earlier, but surgeons were very slow to accept his principles and to adopt his methods with confidence, and especially to apply them to do pioneer work in the dangerous area of the upper abdomen.

Before Lister's time little was attempted beyond the opening of abscesses and cautious slitting of sinuses for the extraction of stones. Through all the years that had gone before, medicine had little to offer beyond relief of pain by drugs. As late as 1890 a distinguished physician confidently advocated massage as a means of expelling stones from the bile-ducts into the duodenum.

In 1733 Petit[2] had suggested and described cholecystotomy, but the fear of peritonitis was so great that the operation was not actually performed until 1867. At this date J. S. Bobbs,[3] exploring for a supposed ovarian cyst, found and opened a gall-bladder distended with mucus, and extracted about 50 small stones, closed the gall-bladder and dropped it back; and the patient recovered. In 1878 Marion Sims performed cholecystostomy in a very late case of jaundice due to gall-stones, but the patient, who was very ill and bleeding at the nose, died soon afterwards; and in 1879 W. W. Keen had a similar experience. In August of the same year Lawson Tait[4] successfully removed a large stone from the gall-bladder and a small one from the cystic duct. The edges of the incision in the gall-bladder were sewn to the skin. By 1885 he had operated upon 15 patients, and in 1889 he published a list of 55 cholecystostomies with only 3 deaths. By this time surgery was benefiting by the teachings of Lister, and operations upon the gall-bladder were rapidly increasing.

In June, 1885, Mayo Robson, "with all the usual measures as to cleanliness, and with full antiseptic precautions, including the spray," successfully performed his first cholecystostomy, and in 1892 published his stimulating book upon gall-stones, with full details of 41 operations. Since then, thanks to the work of the Leeds School, and of many other ons at home and abroad, the surgery of the bile- has advanced by leaps and bounds (Fig. 1).

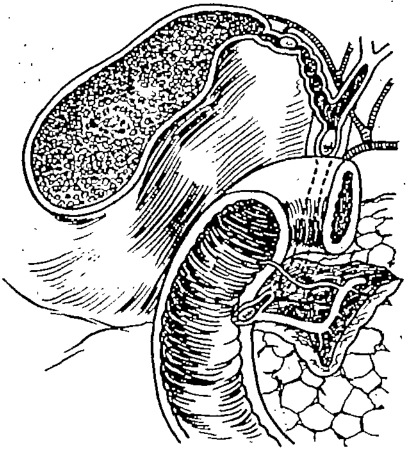
e of the most recent contributions from Leeds valuable statistical study of cholelithiasis by ross,[5] based on a series of 9531 autopsies on ts of all ages performed at the Leeds Infirmary the years 1910 to 1926 inclusive. In this 802 (or 8·4 per cent.) were the subjects of thiasis. Dr. Gross concludes that obesity has ter influence than pregnancy upon the formagall-stones; that gall-stones are only twice as n in women as in men; and that they do not nore frequently in married than in single women. so emphasises the frequent association of gall- with inflammation and cancer of the gall-r and bile-ducts.

knowledge of the abnormalities of the bile-nd of the arteries associated with them has been led by Flint.[6] Descomps[7] and Eisendrath[8] lready drawn attention to these important variations. Mayo Robson, in his book already mentioned, described the following six operations:—

1. Cholecystostomy, or drainage of the gall-bladder.
2. "Ideal Cholecystotomy": in this operation, after the stones had been removed, the gall-bladder was closed and dropped back into the abdomen.
3. Cholelithotrity, or crushing the stones.
4. Cholecystectomy, or removal of the gall-bladder.
5. Choledochotomy, or incision of the common bile-duct.
6. Cholecystenterostomy, or joining the gall-bladder to the bowel.

Cholecystostomy was the operation of choice. At first the gall-bladder was sewn to the skin, but later to the aponeurosis, to lessen the risk of fistula. It took some time for surgeons to learn that a rubber tube sewn into the gall-bladder in an airtight manner gives the best, simplest, and safest drainage. This is a good operation, and is especially useful for bad subjects and for surgeons lacking great experience. It saves lives, without endangering the bile-ducts.

FIG. 1.



Anatomy of the biliary apparatus. Stones are shown in the cystic duct, common bile-duct, and ampulla of Vater. The pancreatic duct of Wirsung and the accessory duct of Santorini are shown, the latter opening separately into the duodenum.

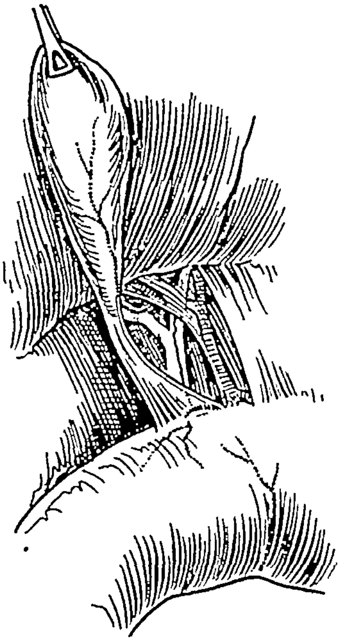
"*Ideal Cholecystotomy*" was abandoned as too dangerous—leakage and peritonitis having followed in a number of cases.

Cholelithotrity was introduced by Lawson Tait and was almost exclusively used for stones impacted in the bile-ducts, whence their extraction by incision was considered too difficult and dangerous. The stones were crushed between the finger and thumb, with padded forceps, or split by means of a fine round needle. This method, although useful at a pinch, is crude and apt to be followed by recurrence, because of the debris left in the ducts.

Cholecystectomy was introduced by Langenbuch[9] in 1882. His first operation for the removal of a calculous gall-bladder was successful, but two out of his first four operations were fatal—one from peritonitis and the other from an abscess of the choroid plexus. The operation was rarely done for some years. Robson only did it once in his first 40 cases, and only 47 cholecystectomies were recorded up to 1890. Now it is the operation of choice for most diseases limited to the gall-bladder and cystic duct, because it is the most radical and generally successful.

For many years only the serious effects of gall-stones were treated by surgery; but with increasing knowledge, acquired from operations and the study of early symptoms, both physicians and surgeons now endeavour to forestall these serious consequences, and even to prevent the formation of gall-stones, by preventing or eliminating the infection which almost constantly precedes it. This is a high aim, and offers great opportunities both for preventive medicine and preventive surgery. Dr. A. F. Hurst[10] has made valuable contributions to the medical treatment of cholecystitis. At present, operations on the bile tract are rapidly increasing in number.

FIG. 2.



The relations of the bile-ducts and blood-vessels as they lie in front of the foramen of Winslow. Variations are very common.

While contemplating this extension of surgery, the beginner should never forget that the present great success of operations upon the gall-bladder and bile-ducts, carried out by experts, can only be obtained by those who take the greatest pains to train themselves in this difficult branch of surgery, and to observe most scrupulously the necessary precautions. Much can be learnt from a careful study of the anatomy, physiology, and pathology of the bile apparatus, and especially the important and confusing changes in the surrounding tissues produced by inflammation. But the perfect skill and judgment which can save a surgeon from the pitfalls that beset his path can only be attained by watching, assisting, and operating under the supervision and encouragement of a master in this special branch of surgery. Thus, with perfect training and greater care, we ought to see and hear less of those injuries to the bile-ducts which demand difficult reconstructive operations. Here, prevention is far better than cure.

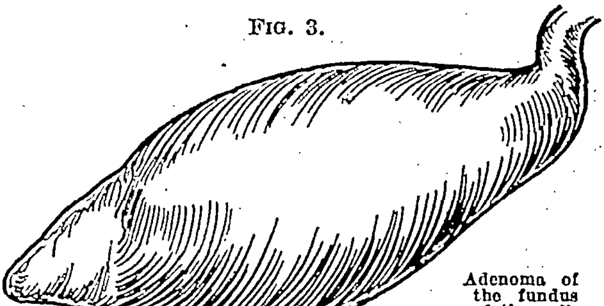
ANATOMICAL VARIATIONS OF THE GALL-BLADDER, BILE-DUCTS, AND BLOOD-VESSELS.

The *gall-bladder* varies considerably in position and size, and when it is placed high up and far back in the right loin or embedded in the liver substance it may be very difficult to deal with. Rarely it is double, divided, or absent; but frequently, as a result of disease, it is either contracted or very large; and sometimes it is so adherent to important structures as to be difficult to define or unsafe to remove.

Bile-ducts.—The cystic duct is often long, running parallel to and adherent to the common hepatic duct which it may join behind the duodenum. On the contrary, it may be, or appear to be, very short or absent. Under these circumstances, it is easy to buttonhole or divide either the common hepatic or the common bile-duct. According to Flint, an accessory right hepatic duct is present in 15 per cent. of cases. It usually discharges near the angle of union of the cystic and common hepatic ducts, and is apt to be divided during removal of the gall-bladder. If this accident passes without recognition and treatment, and the wound is not drained, leakage of bile and secondary infection may be disastrous by causing local or diffuse peritonitis (Fig. 2).

Arteries.—The so-called normal arrangement of the arteries was found by Flint in only 60 of his 200 consecutive dissections. The relations of the vessels to each other and to the ducts are so variable that constant care is necessary to avoid mistakes which may lead either to severe bleeding or to the accidental tying of the right hepatic artery. The bleeding may be almost impossible to stop without seriously damaging the bile-ducts in the depths of the wound. Tying the hepatic artery is a grave error, which is bound to interfere with the nutrition of the liver and may lead to the death of the patient. These mistakes can be avoided only by keeping very close to the gall-bladder and its duct, by using gauze dissection, and by examining each vessel very carefully before it is tied and divided. The large size of the right hepatic artery should save it from confusion with the cystic artery.

FIG. 3.



Adenoma of the fundus of the gall-bladder.

A branch of the gastro-duodenal or of the pancreatico-duodenal, or even one of these arteries, itself may lie in front of the common bile-duct just above the duodenum where it may be lacerated when the duct is hurriedly opened without carefully separating its coverings.

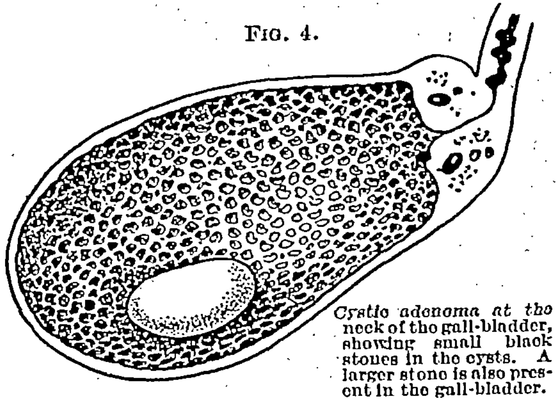
DIAGNOSIS.

Many advances have been made in the diagnosis of cholecystitis and cholelithiasis. As about 10 per cent. of the population have gall-stones, and many more have cholecystitis, there are plenty of opportunities for testing new and old methods of diagnosis. But gall-stones may lie dormant for long periods, and may be discovered accidentally during routine examinations or even after death.

In 1908 Lord Moynihan,[11] our President, gave us an excellent and most helpful account of the "inaugural" symptoms of cholecystitis. A careful study of the clinical history, symptoms, and signs enables us to make a correct diagnosis in a large majority of cases.

Simple radiography shows us the shadows of some opaque gall-stones and thick-walled or calcified gall-bladders. It may show other opacities, such as calcified glands; it should always be tried before cholecystography, because it may make the latter superfluous.* With the aid of the opaque meal,

FIG. 4.



Cystic adenoma at the neck of the gall-bladder, showing small black stones in the cysts. A larger stone is also present in the gall-bladder.

---

* Dr. J. M. Redding has kindly lent me the slides illustrating this part of my lecture.

radiography indicates pressure or traction of the distended or retracted gall-bladder upon the stomach, duodenum, or colon; but these methods only give correct results in about 80 per cent. of cases. The discovery of cholecystography by Graham [13] and Cole in 1923 was a great advance; it has already borne much fruit, and promises more to come, when its merits and possibilities are more widely appreciated. Whereas simple radiography, even with the aid of opaque meals, rarely gives any indication of cholecystitis or of small or non-opaque gall-stones, Graham's method helps us to an early diagnosis of all these. It is particularly valuable in demonstrating obstruction of the bile-ducts before cholecystitis has developed or become recognisable. Obstruction of the cystic duct by a stone too small to cast a shadow, by torsion, valvulation or bands, can thus be recognised and radically treated at an early stage. It also estimates the power of the gall-bladder to concentrate and to expel bile, and of the liver to secrete it. These add much to the range and value of diagnosis.

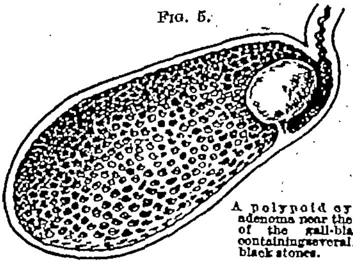
Graham's method is invaluable in the differential diagnosis of diseases of the gall-bladder from those of the alimentary and urinary tracts. The pure dye,† given with care, and in suitable doses, rarely does any harm, but it ought not to be given to patients suffering from heart disease, atheroma, abnormal blood pressure, or to those affected with chronic jaundice, cholangitis, or threatened with uræmia or hepatic insufficiency. The test is a little more accurate when the drug is given intravenously, but it is more convenient and is often considered safer when given by the mouth. Various writers estimate the accuracy of this method of diagnosis as from 80 to 97 per cent.

GENERAL INDICATIONS FOR OPERATION.

The following are the chief indications for operations upon the biliary tract:—

1. *Obstruction.*—(*a*) Of the cystic duct, as indicated by typical attacks of biliary colic with tenderness in the right hypochondrium, and often a palpable gall-bladder. Here cholecystographic evidence of defective filling may give valuable confirmation. (*b*) Of the common bile-duct, as indicated by recurrent attacks of biliary colic and jaundice, perhaps with fever; or increasing and persistent jaundice without colic, generally due to carcinoma of the pancreas or chronic pancreatitis. Great care is taken to exclude other causes of jaundice, such as cirrhosis or malignant disease of the liver.

FIG. 5.



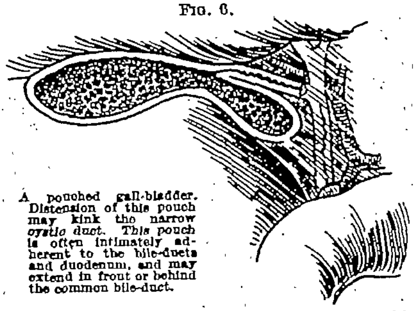
A polypoid cystic adenoma near the neck of the gall-bladder, containing several small black stones.

2. *Irritation and infection* of the gall-bladder as indicated by chronic flatulent dyspepsia, pain and tenderness over the gall-bladder; and cholecystographic evidence of disease or of stones in the gall-bladder.

The mere demonstration of gall-stones or cholecystitis is not sufficient indication for operation. In many they cause no appreciable discomfort, or *only such as* can be relieved by medical treatment. But we have no medical means of dissolving or evacuating the stones, although stones sometimes pass spontaneously along the ducts, or escape through fistulæ into the gastro-intestinal tract.

When symptoms persist or recur in spite of medical treatment, it is generally wise to recommend early operation so as to prevent a high mortality and other serious consequences of delay such as: (1) suppuration, perforation, peritonitis, acute and chronic septicæmia, osteo-arthritis; (2) jaundice and cholangitis, with risk of cholæmia and hæmorrhage; (3) cancer [14] of the gall-bladder, which develops according to Rolleston [15] and others in at least 5 per cent. of all cases of gall-stones. The danger of this complication is greater than that of operation; (4) intestinal obstruction by gall-stones which have ulcerated into the bowel; (5) pancreatitis; (6) hepatic insufficiency; (7) cardiac degeneration.

FIG. 6.



A pouched gall-bladder. Distension of this pouch may kink the narrow *cystic duct.* This pouch is often intimately adherent to the bile-ducts and duodenum, and may extend in front or behind the common bile-duct.

When possible it is safer to wait for a quiet interval before operating, so as to allow thorough investigation and preparation of the patient. Fortunately, the acute symptoms, such as colic, jaundice, and fever, generally subside under careful medical treatment; for, unlike the appendix, the gall-bladder rarely perforates or sets up spreading peritonitis. When signs of spreading peritonitis develop, or an enlarged, tender gall-bladder can be felt, and symptoms such as vomiting, fever, and rigors do not abate, or signs of acute pancreatitis develop, an immediate operation is necessary. Similarly, when jaundice, associated with fever, fails to clear up under medical treatment, an early operation offers the best hope.

These emergency operations should be limited to simple drainage of the gall-bladder or common bile-duct. Radical operations can be carried out later when the patient is better, the liver function is restored, and sepsis has subsided.

PREPARATION.

Much has been done in recent years to make operations safer by improving the preparation of patients, and this applies with special force to the surgery of the bile-ducts, which is beset with special dangers.

The patient is kept at rest, preferably in bed, for two or three days, and dieted. Plenty of sugar and glucose and bicarbonate of soda are given by the mouth, rectum, or even intravenously in all cases where failure of the liver functions is feared. Hexamine is given as a biliary antiseptic. All septic sources in the mouth, nose, and throat are treated in time to lessen the risk of pulmonary complications. When the patient is jaundiced and clotting of the blood is delayed, 5 c.cm. of a 10 per cent. solution of calcium chloride is injected intravenously for two or three days before the operation. If this fails to bring the clotting time to the normal, or there is marked anæmia, one or more transfusions of blood may be given with great advantage.

ANÆSTHETICS.

Chloroform is best avoided in these cases owing to its destructive effects on liver cells. An injection of morphia gr. 1/4 and atropine gr. 1/100 is given 45 minutes before the operation. Ether and oxygen are administered. Some prefer gas and oxygen, but this rarely affords enough muscular relaxation. Novocain injected into the free edge of the lesser omentum and near the neck of the gall-bladder lessens shock and increases relaxation. For bad subjects, twilight sleep, followed by local anæsthesia suffices, especially for simple operations. Spinal anæsthesia with a little gas and oxygen is also valuable.

---

† Graham and Cole prefer the intravenous administration of 2·5 g. of phenoltetraiodophthalein. For oral administration they use 4·0 to 5·0 g. of tetraiodophenolphthalein."

Incisions.

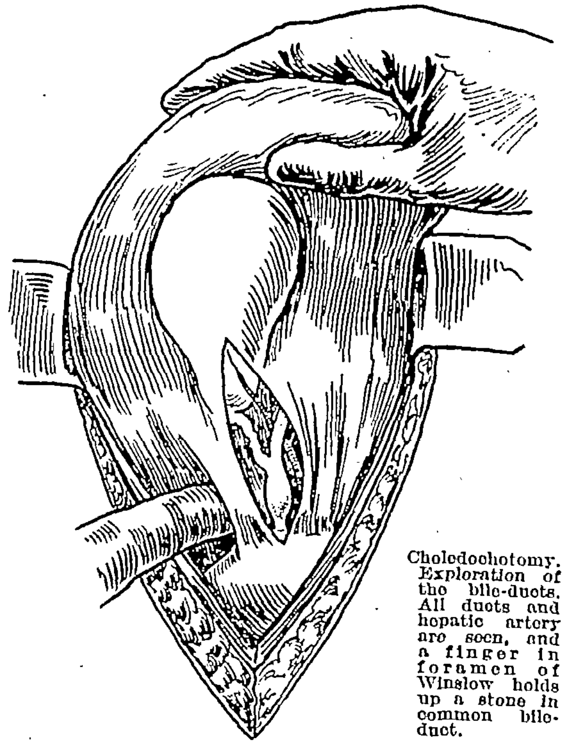
I find that Kocher's incision, which divides the whole width of the rectus muscle and its sheath 1 inch below the right costal margin, gives the best access for cholecystectomy in fat and muscular patients. It is very easy to close, and is rarely followed by ventral hernia, although it allows good drainage at its outer angle. It does not rob the rectus of an adequate nerve-supply.

The right paramedian incision gives the best access to the lower part of the common bile-duct, to the pancreas, and to the appendix adherent low down in the abdomen or pelvis. A stab wound for drainage allows the paramedian incision to be completely closed to lessen the chance of ventral hernia. For secondary operations a fresh site for the incision is generally desirable, so as to avoid adhesions and allow a free exposure, with less risk of hernia or damage to adherent organs.

Choice of Operation when the Parts are Exposed.

The abdomen having been opened, the surgeon, whenever possible without adding to the patient's risk, rapidly explores the whole abdomen so that he may discover and remove any source of sepsis. In many cases it is necessary to remove a diseased appendix, and in some a gastric or duodenal ulcer may need attention. The gall-bladder and bile-ducts are examined with the greatest care, so that no stone or disease may be overlooked. It is very important to remember that stones may rest in the common bile-duct for years without causing jaundice. At my first cholecystectomy the gall-bladder contained 90 small faceted stones, but I overlooked the hundredth, which was in the common bile-duct. It caused frequent attacks of colic without any jaundice during four years before I removed it.

FIG. 7.

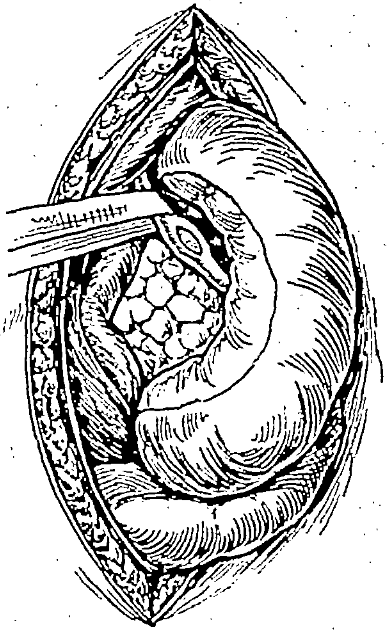


Choledochotomy. Exploration of the bile-ducts. All ducts and hepatic artery are seen, and a finger in foramen of Winslow holds up a stone in common bile-duct.

When the common bile-duct is dilated, especially with the gall-bladder present and active, the ducts must be palpated with extreme care, and often it is necessary to open the common bile-duct and to examine the passages from within.

(*a*) *When the disease is limited to the gall-bladder and cystic duct* the choice lies between cholecystectomy and cholecystostomy (Fig. 3). It is the ideal of the surgeon to operate while the disease is limited to the gall-bladder and cystic duct so that he can eradicate it. Fortunately, the gall-bladder is not indispensable, although it has been shown to have several interesting functions. Certain animals, such as the horse, the deer, and the rat, have no gall-bladder, and thousands of human beings who have had it removed get on well without it. Skilful removal in suitable cases carries little risk; therefore we need not hesitate to remove it when this is necessary. Removal is far better than drainage, for the following reasons:—

FIG. 8.



Retroduodenal choledochotomy. The stone is firmly impacted in the second part of the common bile-duct, behind the duodenum, which has been mobilised and turned over to the left. The duct was embedded in the head of the pancreas.

1. Drainage rarely cures cholecystitis because the infection lurks deeply in the walls of the gall-bladder.
2. A diseased gall-bladder being the chief factory of gall-stones is better removed to prevent recurrence.
3. It is extremely difficult to make sure of removing all the stones from the cystic duct and the gall-bladder. It is often easier, cleaner, and therefore safer to remove the gall-bladder and cystic duct without opening them.
4. Excision of the gall-bladder may get rid of an unsuspected early cancer or precancerous condition. The results of such operations are extremely favourable. I have several patients living and well many years afterwards, but it is usually too late to cure a cancer of the gall-bladder which has been recognised before the abdomen has been opened.

The chief indications for cholecystectomy are irreparable wounds and injuries or diseases limited to the gall-bladder and its duct. The most important of these diseases are: acute, chronic, and recurrent cholecystitis, especially when associated with gall-stones; typhoid infection, making a patient a typhoid carrier; gangrene, perforation, empyema, hydrops, or mucous fistula of the gall-bladder due to obstruction of the cystic duct by stone, torsion, kink, band, or stricture; fibroma, adenoma, papilloma, or carcinoma and biliary fistula or chronic jaundice due to kinking of the common bile-duct following cholecystostomy (Fig. 4).

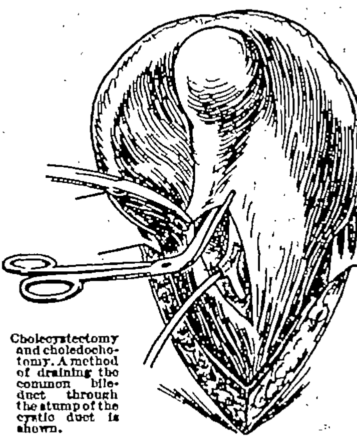
If every gall-bladder is carefully examined after removal, I believe that more new growths will be discovered. The figures illustrate some adenomata which I have removed; several contained small black stones. I think they have an important bearing upon stone and cancer formation (Fig. 5).

A. M. Shipley[14] has collected 22 cases of acute torsion of the pendulous gall-bladder; cholecystectomy was performed on all but one of these cases. This condition is almost limited to women over 60 years of age.

It is not wise to undertake cholecystectomy when the patient is very ill, old or feeble, or when the mechanical difficulties and dangers of the operation are too great for the operator. Cholecystostomy is safer under such circumstances, care being taken to remove all the stones, if possible. If the symptoms recur, secondary cholecystectomy can be performed under more favourable circumstances. Neither should cholecystectomy be attempted when there is chronic jaundice with consequent risk of hæmorrhage, unless the normal coagulation time has been restored by treatment; nor when there is infective cholangitis or hepatic insufficiency. Cholecystectomy should never be performed unless it is certain that the common bile-duct is patent.

It is easy enough to recognise gross disease of the gall-bladder, but slight abnormalities are as easily overlooked. If the clinical history and examinations, especially cholecystography and the finding of bacteria in the duodenal bile, incriminate the gall-bladder, it is generally wise to remove it although it may not look very abnormal. Other important signs of disease are: thickening, with change of colour to pink or grey; small stones often difficult to feel; white spots indicating cholecysterosis or strawberry gall-bladder; an excess of fat in the wall; enlargement of the sentinel lymphatic gland near the cystic duct; evidence of hepatitis, perihepatitis, and especially subcapsular fibrosis near the gall-bladder; and adhesions to the duodenum or colon (Fig. 6). Kinking, bands, adhesions, and deformities at the neck of the gall-bladder may be concealed until they have been fully exposed after dividing their peritoneal sheath. I have demonstrated several good examples of valvular obstruction of the neck of the gall-bladder while operating for Dr. Hurst at New Lodge Clinic.

FIG. 9.

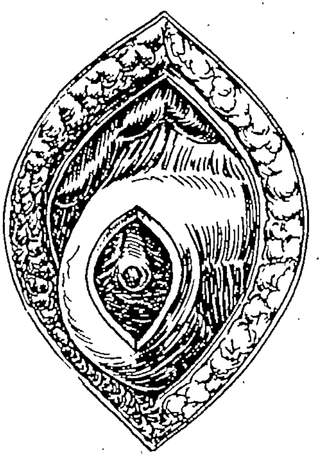


Cholecystectomy and choledochotomy. A method of draining the common bile-duct through the stump of the cystic duct is shown.

(*b*) *When the common bile-duct is affected*, obstructive jaundice generally follows, and is often due to (1) stone in the common bile-duct; (2) carcinoma of the head of the pancreas or bile-duct; (3) chronic pancreatitis.

The choice of operation is between choledochostomy, cholecystogastrostomy, and cholecystostomy (Fig. 7). When jaundice is associated with colic, it is generally due to impaction of stone or other foreign body in the common duct. It is far better to remove the obstruction, if possible, than to make a short-circuit between the gall-bladder or bile-duct and the stomach or intestine. A stone impacted in the lower part of the common bile-duct is best moved back into the first part of the duct and held there before the latter is opened. If the stone cannot be moved back and extracted from the first part of the duct, it may be necessary to mobilise the duodenum and to remove the stone from behind (Fig. 8). When the stone is impacted at or near the duodenal papilla, the trans-duodenal route is a good and safe one—far safer than prolonged efforts to displace or to crush the stone (Fig. 9). Whenever the first or second part of the common bile-duct has been opened I insert a tube for drainage; once after closing the duct I had to remove a fibrinous clot from it ten days later, and in another case in which the drainage-tube did not enter the duct, bile accumulated in the lesser sac of the peritoneum, causing serious symptoms which were relieved by drainage some days later (Fig. 11). On various occasions I have found foreign bodies (other than stone) in the common bile-duct, such as hydatid daughter cysts discharged from the parent cyst in the liver, and a slough derived from the turned-in edge of the gall-bladder after cholecystostomy.

FIG. 10.



Duodenocholedochotomy. The second part of the duodenum is brought into the wound and packed off. Vertical incisions are made in the anterior wall of the duodenum and end of the bile-duct.

If the jaundice is due to chronic pancreatitis or carcinoma of the head of the pancreas, I prefer cholecystogastrostomy to any other treatment. It is much better than draining the gall-bladder or common bile-duct to the surface of the skin, and it appears to be safer, easier, and better to drain the distended gall-bladder into the stomach than into the duodenum, small or large intestine. Fistula or obstruction occasionally followed an anastomosis with the duodenum; kinking and vomiting often followed union with the jejunum; and infection of the liver is especially likely when the gall-bladder is joined to the colon. Chronic pancreatitis, with jaundice, is generally cured by cholecystogastrostomy (Fig. 11). I have several patients who have survived many years in good health. The operation is worth while, even for cancerous obstruction of the common bile-duct, for the jaundice with intolerable itching and risk of bleeding are cured, and life may be prolonged in comfort and efficiency for many months or even for years.

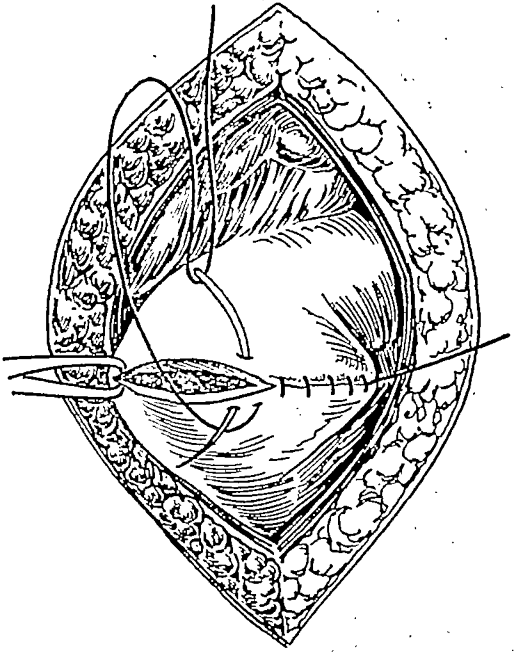
RECONSTRUCTION OF THE BILE-DUCTS.

Reconstruction of the bile-ducts is required occasionally after excision of growths, but more commonly after accidental injuries during operation. It is easier, and far better, to make the necessary repair immediately, before inflammation has changed and confused the anatomical appearances, and before ascending hepatitis and hepatic insufficiency have developed. Direct suture over a rubber tube is usually practicable in early cases. Later it may be impossible to find or to make use of the lower part of a divided duct. Then it becomes necessary to join the upper, often dilated, part of the duct to the duodenum, either by direct suture after the Mayo[17] method, or by a flap operation after Walton's[18] excellent plan. These operations are notoriously difficult and dangerous.

RESULTS.

Mortality.—The death-rate of operations upon the gall-bladder and common bile-duct is surprisingly low, considering the complicated nature and difficulties of these operations. Graham and his colleagues, in their last 309 cholecystectomies for both acute and chronic cholecystitis, with or without stones, had a mortality of 2·8 per cent. During the same time they performed 11 cholecystostomies with a mortality of 18 per cent., this operation having been performed only in those cases which were the worst risks. The death-rate of choledochotomy is naturally higher because the patients requiring it are often bad subjects, who have suffered for years and have developed complications such as secondary heart disease, cholangitis, hepatitis, or pancreatitis, and are now peculiarly liable to hæmorrhage and pulmonary complications, and above all are apt to suffer from hepatic insufficiency or nephritis. Graham had a mortality of 11·9 per cent. in 42 cases of removal of stones from the common bile-duct. Infective or suppurative cholangitis makes the mortality very high.

FIG. 11.



Duodenocholedochotomy. The wound in the duodenum is drawn into the transverse position and closed with two layers of catgut suture and sealed over with a flap taken from the *mesocolon just below it.*

Between July, 1916, and January, 1929, there were 251 operations for gall-stones and cholecystitis in my wards at Guy's Hospital, with 7 deaths—a mortality of 2·8 per cent. 202 of these patients were women, with 4 deaths; 49 were men, with 3 deaths. My junior colleague, Mr. Lancelot Bromley, operated upon some of these patients, and my surgical registrar operated on some under my supervision. During the last ten years I operated upon 175 private patients for all kinds of diseases of the gall-bladder and bile-ducts, with 11 deaths—a mortality of 6·3 per cent.

There were 10 cholecystotomies, with 2 deaths.
" " 135 cholecystectomies, " 4 "
" " 25 choledochotomies, " 5 "
" " 5 cholecystogastrostomies, with no death.

The two deaths following cholecystotomy were due to perforation of the gall-bladder causing subdiaphragmatic abscess in one case and general peritonitis in the other. Two deaths following cholecystectomy were due to pneumonia and pulmonary embolism. Another death was due to perforation of the gall-bladder with suppuration in the liver; and the last occurred in a patient suffering from severe hæmolytic anæmia secondary to streptococcal infection of the gall-bladder. The five deaths following choledochotomy were due chiefly to hepatic insufficiency in late cases. Of my private patients, 126 were women, with 7 deaths; 49 were men, with 4 deaths. There were more than 3 women to 1 man in my lists of 426 operations. D. P. D. Wilkie and others have also found the mortality higher in private patients, who are apt to wait too long and to try various treatments before operation.

It is interesting that both Graham and Blalock also find the risk of all these operations much greater in men than in women.

Ultimate Results—Cholecystostomy affords complete and permanent relief of symptoms in only about 45 per cent. of cases.[19] The persistence or recurrence of symptoms are often due to leaving some stones behind, to the persistence of inflammation in the walls of the gall-bladder, or to the formation of new stones. Secondary cholecystectomy or choledochostomy are often required.

Cholecystectomy affords complete and permanent relief in about 86 per cent. of cases.[20] Müller[21] found the results completely satisfactory in 84·4 per cent. of stone cases and 70 per cent. of the cases of cholecystitis without stones. Whipple gives similar figures. At least 80 per cent. of my results were good. The more accurate the diagnosis, the better the result.[22] Hurst[23] has pointed out that some temporary recurrence of symptoms may follow cholecystectomy, owing perhaps to spasm of the sphincter of Oddi with dilatation and other changes in the bile-ducts, secondary to the loss of the gall-bladder. Under these conditions spasmodic pains may develop and be attributed to stones left behind in the common bile-duct. Medical treatment will generally cure these symptoms and should be well tried before submitting the patient to another operation which may not discover any stone or obstruction in the bile-ducts. Adhesions between the stomach or duodenum and the gall-bladder fissure of the liver may cause pain and vomiting, but they very rarely lead to pyloric or duodenal stenosis, calling for operation. Persistence of symptoms after operation may be due to residual infection in liver or pancreas, to stones overlooked in the ducts, to errors in diagnosis, to osteo-arthritis of the spine, spastic or mucous colitis.

Choledochotomy is generally followed by great success, but occasionally symptoms persist or recur owing to a stone left behind or coming down from the liver, to a stricture in the duct or at the duodenal papilla, to blood clot or fibrin in the duct, to pancreatitis, or to the formation of fresh stones in a septic, ill-drained gall-duct; such a stone may form round a silk or even a catgut suture, or as has been already mentioned, round a slough of the gall-bladder.

CONCLUSIONS.

Infective inflammation of the gall-bladder is very common, and is difficult to cure medically. It often causes gall-stones, and sometimes cancer, to form in the gall-bladder.

Timely radical operation has a low mortality, and offers a very good chance of cure. Delay often leads to serious and dangerous consequences. The results of operations upon the gall-bladder and bile-ducts are extremely satisfactory, and compare favourably with those obtained in any other branch of surgery.

THE SULFOSIN TREATMENT OF GENERAL PARALYSIS

AND OTHER DISORDERS.

BY KNUD SCHROEDER, M.D.,
PHYSICIAN-IN-CHIEF TO THE ODENSE COUNTRY AND CITY HOSPITAL, DENMARK.

AT the thirteenth Northern Congress of Internal Medicine at Copenhagen in June, 1927, I gave a preliminary report* on the therapeutic effects I had observed after the administration of sulphur in the form of sulphurated oil ("sulfosin"). In general paralysis, repeated injections of sulfosin, producing a rise of temperature to 104° F. or higher, had a therapeutic effect similar to that of malarial treatment without its dangers and drawbacks. Further, I pointed out that the sulfosin treatment would be very likely to prove effective in other syphilitic and certain non-syphilitic lesions of the central nervous system.

My subsequent results have confirmed this view, which has now been supported by several other authors, who seem to assign to sulphur treatment a prominent part in the therapy of these lesions.

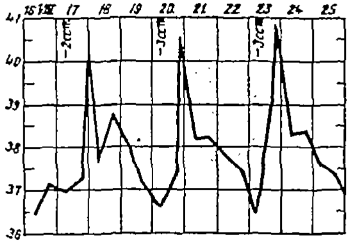
Sulfosin treatment is innocuous and can be applied everywhere—even in the most remote corners of the world—without any need for special hospitals or clinics. It is perfectly controllable; the fever can be regulated very accurately by the size of the injections, and can be made to subside at any time by their discontinuance. It can be instituted unhesitatingly even in infancy and old age, and in patients who are suffering from complications—even advanced circulatory lesions and albuminuria—that contra-indicate infection therapy. Another advantage is that the treatment may be given successfully to patients who have proved refractory to infection therapy (or in whom later injections did not take), and also to patients who cannot stand any other antiluetic treatment.

The preparation, sulfosin leo,* is a 1 per cent. solution or suspension† of sulphur (sulfur sublimatum subtilissimum) in olive oil, sterilised, according to my method, by heating in a hot-air oven, and sealed in ampoules of 1 to 10 c.cm.

Technique.

Sulfosin is injected deeply intramuscularly on the lateral side of the femur, preferably between the upper and middle thirds. The morning is the best time for injection, since the maximal temperature sets in about 12 hours later (8 to 14 hours). As the maximum is of very short duration, the temperature should be noted every hour or half hour when six to eight hours have elapsed after the injection, until the maximal height and subsequent fall have been recorded. It is important to know the maximal temperature reached, because the size of the injections will depend on it, the treatment aiming at a rise to 40° C. (104° F.) or more (see figure).

The initial dose is small (0·5 to 1·0 c.cm.), and the dose is increased by about 1 c.cm. at each injection until it eventually amounts to 10 to 12 c.cm. The temperature rises with the increase of dose. The injection is repeated when the temperature has dropped to normal—usually within 24 to 48 hours—so that the injections are given at a rate of about two a week. As a rule, ten injections constitute a series, and a new series may be started about two weeks after the preceding one. Usually two or three series are sufficient, but more may be given if desirable. At the site of injection there is often some tenderness for one or two days, culminating with pains in the femur radiating downwards; these pains may be treated with hot wet dressings or electric heat. Persisting tenderness and stiffness of the femur are treated by massage. A temperature of 104° F. is occasionally accompanied by a brief spell of indisposition.



Temperature chart (centigrade) showing rises of temperature *as a result of injections of sulfosin.*

Results in General Paralysis.

General paralysis was the first disease in which I experimented with this therapy. In February, 1924, a patient with tabo-paralysis was admitted to my department, and I had at that time no way of giving malaria treatment. So I ventured to treat him with injections of sulphurated olive oil, and the experiment turned out far more successful than could have been expected. He was admitted as an irretrievable wreck, and he was discharged in full remission, restored to life and to his profession, at which he is still working. Since then I have treated 12 cases, some more recent and some non-treated cases of long standing. Of these 12 cases, 4 were discharged in full remission, with fully restored capacity for work, and apparently cured (observation periods: 5, 4, 3, ½ years); 1 in good remission, but with a psychic defect, lack of initiative (observation period: 2 years); 1 in remission (treatment not completed); and 1 somewhat improved. Four have shown no change in their condition and 1 died (treatment not completed, but serological improvement; the patient died from pyelonephritis and pneumonia). Thus 58 per cent. of the patients were discharged in remission, including 33·3 per cent. who were apparently cured, and had fully recovered their capacity for work.

Similar favourable results have recently been obtained by Marcuse and Kallmann[1] with more advanced cases than are generally met in clinics and hospitals. In 82 cases these authors obtained a marked improvement (with a prognosis of "persisting improvement") in 19 per cent. In 41 per cent. of the cases the authors found "fair to marked improvement" in the somatic as well as in the psychic condition. The fact that these patients were not returned to their families was only due to "unfavourable domestic conditions." Warstadt[2] has treated 11 patients with sulfosin. He finds its favourable effect

---

to be unquestionable, and he concludes that this remedy "appears to be a substitute for malaria, and preferable to other remedies of this kind." Marcuse and Kallmann, as well as Warstadt, report several cases of favourable effect where malaria treatment had failed, and Pires[3] records two cases that were refractory to malaria and in which sulfosin treatment gave good results. Stiefler[4] is satisfied with the results he has obtained with sulfosin treatment. He says: "From our observations sulfosin appears to be a very valuable fever-producing remedy; its efficacy is evident from its influence on the clinical symptoms as well as on the serological findings." Marcuse and Kallmann conclude that sulfosin not only eliminates the dangers connected with an infectious process but, in addition to its equally great power of producing fever, it has a roborant curative effect.

I have examined the serological findings in my patients as far as possible, and found the Wassermann reaction negative in the four patients who were discharged in full remission (observation period: ½ to 4 years). These cases also showed a marked fall in the cell content of the cerebro-spinal fluid, even down to normal in some instances. Among the four patients who showed no psychic changes, two became sero-negative, and their cell content fell off (in one case from 494/3 to 6/3, in the other from 31/3 to 4/3). In sulfosin treatment, however, the clinical effect is no more parallel with the serological effect than it is in malaria treatment. The serological changes may become manifest much later.

These findings suggest, therefore, that the therapeutic effect of sulfosin treatment in general paralysis is analogous to that of malaria therapy.

Results in Other Syphilitic Lesions.

My patients with general paralysis were also under general antiluetic treatment (salvarsan, mercury, and bismuth), so that one could not with certainty attribute the favourable effect on the humoral syndrome to the action of sulfosin alone, even though our experiences so far really suggest, I think, that the sulfosin treatment is the principal factor. To decide whether, or to what extent, syphilis is influenced by treatment with sulfosin alone it was necessary to treat some syphilitics exclusively with sulfosin. Four patients with cerebro-spinal syphilis were accordingly treated with sulfosin alone.

Before treatment, the first patient (female, aged 31) showed a blood Wassermann of 0.0.0.10.100,‡ and a cerebro-spinal Wassermann of 0.40.100. Her cell count was 150/3. After eight injections of sulfosin the Wassermann reaction in both blood and cerebro-spinal fluid was negative, and the cell content had dropped from 150/3 to 10/3 (within two months).

In the second patient (female, aged 54) the Wassermann reaction in the cerebro-spinal fluid changed within five weeks from 0.0.0.0.0.0.00.100Σ25 to 0.10.00.100Σ2·5 units as a result of 12 sulfosin injections. The cell content subsided at the same time from 240/3 to 5/3.

The third patient (male, aged 57) had been infected with syphilis 32 years before, and had had no antiluetic treatment for 30 years. Within three months 12 sulfosin injections changed his Wassermann reaction in the blood from 0.20.00.100Σ25 to perfectly negative (Σ0). At the same time there was a most remarkable change in the clinical manifestations. On admission he was lying in bed, a hopeless wreck, incapable of shutting his eyes or chewing his food, with signs of bulbar paralysis and total facial paralysis; after three months' treatment he was capable of resuming his work as a drawing-master, and he has attended to his duties during the past 18 months.

In the fourth patient (female, aged 21) the blood Wassermann reaction changed from 0.00.100Σ25 to a complete negative at the same time as the Wassermann reaction in the cerebro-spinal fluid changed from 20.00.100Σ5 to 20.100Σ1·6. The cell content dropped from 231/3 to 23/3.

These changes were accomplished by eight sulfosin injections in one month.

As the changes in the serological syndrome of these patients are far in excess of any spontaneous variation, we may conclude that sulfosin has an antisyphilitic effect. This conclusion is not shaken by the possibility that the same patients might have improved in a similar way on some other antiluetic treatment. Consequently, in sulfosin treatment we have a new, hitherto unknown, remedy *against syphilis of* the nervous system.

I then felt justified in applying sulfosin treatment to some syphilitics who had not shown any signs of cerebro-spinal syphilis and, finally, in making the same experiment on some patients with recent syphilis.

I treated one male who suffered from tertiary syphilitic ulcerated gumma of the left leg. He had been infected and treated 20 years before, but had had no subsequent treatment. On admission the Wassermann reaction in the blood was 40.100. After eight sulfosin injections it was negative with heart extract but positive with syphilitic extract, and the gumma had disappeared.

I then applied sulfosin treatment to a couple of cases of recent syphilis.

The first patient (female, aged 18) had her first eruption with large, confluent, excoriated and partly hypertrophic papules on the genitalia. Sulfosin treatment was started on the day after her admission. Only five days later—after no more than three sulfosin injections—I was astonished to find that the *papules had gone. Two days later even the* marks from the papules had disappeared, and they did not show again. When five sulfosin injections had been given, the Wassermann reaction in the blood had increased very considerably (to 0.0.0.00.100 with Σ100), but it soon began to fall off, and was perfectly negative after 15 injections.§

The other patient (a female, aged 21) had her first eruption with papules in the palms and macular exanthema on the genitalia. After eight sulfosin injections the eruption disappeared and the Wassermann reaction in the blood went to negative.

I have also treated a couple of children (a girl, aged 7, and her brother, aged 5) who were suffering from congenital latent syphilis. They showed no no signs of any particular discomfort, although their temperatures went up to 105° F. In both cases the Wassermann reaction became less positive; in one case it went down to negative with heart extract, weakly positive with syphilitic extract, and Σ0.

I have treated six patients who had latent syphilis. In four of these the reaction became negative within the period of observation. I have also given sulfosin to six patients with syphilitic aortitis; all showed clinical improvement. Two of these patients suffered from angina pectoris; this condition disappeared in one of them, and was considerably improved in the other. A pre-existing albuminuria disappeared in one patient. Finally, there was one patient (male, aged 52) who suffered from aneurysm of the innominate artery and aorta, and who had not been treated for 30 years.

On admission he was in very bad condition, and his blood Wassermann reaction was 0.0.00.100Σ150. Sulfosin treatment was instituted as a last resort, and he received seven injections, with the dose increasing from 0·25 to 2 c.cm., which gave a maximum temperature of 104·6° F. without any discomfort worth mentioning or any particular heart signs. On this treatment the Wassermann reaction in his blood fell to 20.100Σ25. When admitted to hospital the patient had been cyanotic and so dyspnœic that he could not turn in bed nor sit upright, and he could take only liquid food. During the treatment, however, he kept on improving far more than could be expected, and six weeks after admission he was able to walk about and to swallow solid food. Along with this improvement the pulsation over the right clavicle disappeared, and both radial pulses beat alike, a result that was as conspicuous as it was unexpected. One could have sworn that this change was impossible, if one had not seen it develop with one's own eyes.

Beside the remarkable clinical result of sulfosin treatment, this case also shows an unquestionable effect on the Wassermann reaction, and illustrates how well sulfosin may agree even with a patient who has such a severe lesion of the main arteries.

---

‡ All the Wassermann tests are done by the State Serum Institute, Copenhagen. The titration is done in series, using the following quantities of serum: 0·2, 0·1, 0·05, 0·02, 0·01, 0·005, 0·0025, 0·001, 0·0005, and 0·00025; and the figures indicate the hæmolysis in the respective tubes containing amounts of serum in this order. While 0 indicates the absence of any hæmolysis, maximal positive reaction, 100 designates complete hæmolysis, negative reaction. The values between 0 and 100 are the intermediate degrees of hæmolysis.

§ I have several times noticed this variation in the Wassermann reaction during sulfosin treatment, particularly in cases of a recent date. I consider it a biological reaction.

I have already mentioned a case which shows that sulfosin may be given unhesitatingly to patients with renal lesions and albuminuria. I add three more instances of this kind.

One of these patients suffered from chronic nephritis with marked albuminuria, which was not aggravated in spite of seven sulfosin injections (with a maximum temperature of 104·6° F. In another patient albuminuria set in after the administration of 0·15 g. of neosalvarsan with 0·25 g. of bismuth; albumin disappeared from the urine on further treatment with sulfosin alone (two series of ten injections, each amounting to 10·5+49 c.cm. of sulfosin with maximum temperatures of 104·0° F. and 105·1° F. The third patient, who had hæmorrhagic nephritis, received ten sulfosin injections (47·5 c.cm., all told, with a maximum temperature of 104·2° F.), together with 3·0 g. neosalvarsan. On this treatment the urine became free of blood as well as of albumin.

These findings show conclusively, I think, that in these different forms of syphilis sulfosin has an unquestionable effect—not only on the syphilitic products, but also on the infection itself—a fact not previously known. We do not know how this effect is brought about, but I think we have some suggestive points. Sulfosin treatment is not an infection therapy like malaria and recurrent fever therapies, but has this in common with them—that when the active agent is introduced into the sick organism it sets up a reaction which is accompanied by a considerable rise of temperature. This rise of temperature, however, is essentially different from the fever in malaria and typhoid vaccine therapy; for the rise of temperature after sulfosin is more acute than its fall, which is considerably prolonged, so as to make the base of the fever phase unusually wide, and produce a fever curve that is quite characteristic. While this fever is subsiding it frequently runs an intermittent course, which also appears to be characteristic (see figure). This reaction may be non-specific—a sort of "Reizkörper" effect—and especially pronounced in metasyphilitic conditions, but apart from this general effect I think the sulphur has also a relatively specific action, like other "chemically avid" substances.

When given in the proper way sulfosin is a perfectly harmless remedy which can be used with very serious cardiac and renal lesions. Even pregnancy or pulmonary tuberculosis do not positively contra-indicate its use—as I have learned in several cases—if only moderate rises of temperature are induced. It suits patients of all ages. In congenital lues I have given it to two children at the age of one year, and even to a child of three months (starting with 0·1 c.cm.).

Sulfosin Combined with Other Antisyphilitic Measures.

Even though these experiments indicate that sulfosin has quite a marked antiluetic effect, I still think that, as a rule, it should not be used alone but rather in combination with our present antiluetic treatment (neosalvarsan, mercury, bismuth), so that the latter is given either concurrently with or immediately after the sulfosin treatment. I have had plenty of opportunity of establishing that this combination is well tolerated. I have given this treatment to six patients with tabes dorsalis; four were improved. L. W. Harrison has also seen some good effect from the treatment in one case of tabes dorsalis. I have had no opportunity of trying it in tabetic optic atrophy, but Winkler[8] reports a good effect in three out of five cases. Stiefler has treated five cases of this kind without any effect on the optic atrophy, while other tabetic manifestations were partly improved. Amongst other syphilitic eye lesions where the sulfosin treatment may prove of value, one may mention parenchymatous keratitis. Of eight children with congenital syphilis, four had parenchymatous keratitis which improved and cleared up. In my opinion sulfosin had a favourable effect. One of these children was also suffering from osteoperiostitis, which disappeared completely. Harrison has treated two cases of interstitial keratitis with sulfosin, and he has told me that "particularly in one, the effects of the injections of sulfosin were very good, the keratitis clearing more quickly than I have ever seen it."

I have also given sulfosin with other antiluetic treatment to two patients before they had any eruption of the secondary stage, and to 13 patients with the first eruption of syphilis. In all 13 patients the Wassermann reaction became negative, after a preliminary increase in strength in five. The papules and exanthema disappeared rapidly (within 8 to 28 days) in ten of these patients, but more slowly in the other three. In two of the latter cases the neosalvarsan treatment had to be discontinued on account of violent reactions. I have treated four cases of later eruption. Here the papules and exanthema disappeared in 7 to 22 days, and the Wassermann reaction became negative in all.

From the treatment of the 19 patients we most certainly feel that we have obtained a more rapid therapeutic effect, clinical as well as serological, by adding sulfosin to the other treatment. So I think that sulfosin ought to be given as a part of the antiluetic treatment to patients who are admitted to hospital, particularly in such cases where other treatment cannot be given without eliciting some reactions, especially as I have never seen any sulfosin reaction which contra-indicated the continuance of the treatment.

Sulfosin and Non-syphilitic Lesions of the C.N.S.

In view of the favourable results obtained with sulfosin in general paralysis and other cerebro-spinal lesions of syphilitic origin, it was no far-fetched idea to try whether it would prove effective in the treatment of other lesions of the central nervous system which are not syphilitic, but strongly resemble metasyphilitic affections in their clinical manifestations and course. Epidemic encephalitis and disseminated sclerosis resemble syphilis in this way, and may improve somewhat on malaria or typhoid vaccine treatment. I therefore felt justified in trying sulfosin.

I paid particular attention to postencephalitic parkinsonism. I have treated five cases of this kind; four of them, at any rate, were definitely postencephalitic. All five improved—subjectively as well as objectively—after treatment with sulfosin; in four the improvement was very marked, and directly followed the treatment. The patients were very pleased with the treatment—in spite of the subjective discomfort it causes—and it was repeated in several instances at their own request.

In 15 cases of postencephalitic parkinsonism Stiefler found some, although a moderate, improvement. It is possible that sulfosin may also give good results in other manifestations of chronic encephalitis, but my experience in this respect is so limited that I have nothing to say about it. Unfortunately I have not had any opportunity of trying the treatment in the acute stage of epidemic encephalitis; it is not altogether unlikely that the chances of recovery on sulfosin treatment are better in the acute stage than during the later course. In one of my cases of parkinsonism the encephalitic ætiology was questionable; it may have been a case of paralysis agitans. As this patient was benefited by the treatment I have adopted sulfosin therapy for the treatment of paralysis agitans. In this connexion I may mention a case of paralysis agitans which Dr. H. Verploegh, of The Hague, has been treating after consulting with me; this patient "has improved most remarkably—even after four injections of sulfosin."

I have tried sulfosin treatment in three unquestioned cases of disseminated sclerosis, but without any recognisable therapeutic effect. The patients had imperative urination immediately after the injections, probably the result of a local action on the gliomatous process in the medulla. This effect was quite transitory. A similar local effect has been observed by Dr. Ernst Bichel (Wiesbaden) in a patient who, he thinks, showed a continuous progressive improvement after five series of sulfosin injections. Stiefler has treated 12 cases of disseminated sclerosis with sulfosin, and reports some really encouraging results. He says: "At any rate, it has served me well in several cases which did not respond enough to typhoid vaccine. Sulfosin is also preferable to treatment with typhoid vaccine when the patient is markedly debilitated or suffers from circulatory disturbances."

Sulfosin Treatment of Dementia Præcox (Schizophrenia).

In a previous paper on sulfosin treatment I suggested that the remedy might prove effective in dementia præcox. I have since used it in six cases. The treatment has been completed in three, all of whom had such a good remission that they were able to resume their work—one of them with perfectly normal mentality (observation time: 10, 10, and 5 months). Another patient improved somewhat, but nothing is known of his later condition, and one patient showed signs of beginning remission. The undoubtedly favourable result I have obtained in this way is confirmed by a report from Marcuse and Kallmann,[1] who have treated no less than 40 cases of schizophrenia by this method. In 16 of these patients they found a more or less pronounced improvement in such direct connexion with the treatment that they do not question its efficacy. They give four typical histories of patients who recovered and returned to their work. Favourable results are also recorded by Salinger,[6] who has treated 16 cases of schizophrenic psychosis and found improvement in 25 per cent. In treating 50 cases of this kind Loberg[7] has found a similar effect from sulfosin. The final results, however, are not yet available. In view of these findings one can hardly doubt that sulfosin is an effective remedy against schizophrenia. This is very significant; an effective treatment of dementia præcox is particularly desirable because this disease attacks the young and—apart from spontaneous remissions—puts the unfortunate patients in such a pitiful condition that a desire to help them is dictated just as much by compassion for the patients themselves as by the social importance of their recovery.

Summary.

1. In the human organism the administration of sulphur in the form of sulfosin (sulphurated oil) sets up a febrile condition of short duration. Repeated injections may result in a therapeutic effect on a variety of lesions of the central nervous system.
2. The chief of these lesions are general paralysis and other syphilitic lesions of the central nervous system. Experiments on fresh and older cases of syphilis have also shown an unquestionable antiluetic effect from sulfosin injections.
3. Sulfosin treatment may also have a favourable effect on other non-syphilitic lesions of the central nervous system (chronic epidemic encephalitis with parkinsonism, dementia præcox, and disseminated sclerosis).
4. The therapeutic effect produced by sulfosin treatment appears primarily to be a general reaction, associated with the rise of temperature; but there is probably also a specific sulphur effect.
5. Sulfosin treatment is preferable to infection treatment. The results seem to indicate that sulfosin has the same therapeutic effect as infection treatment without its dangers and drawbacks, as sulfosin is perfectly safe and its use is not restricted to special hospitals.

PUNCTURE OF THE CHEST:

ITS OCCASIONS AND TECHNIQUE.*

BY F. G. CHANDLER, M.D., F.R.C.P. LOND.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, CHARING CROSS HOSPITAL; PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK.

THE first principle in the technique of puncture of the chest is that it should be done exactly as the operator would like to have his own chest punctured. This would *not* mean no local anæsthetic, a blunt needle, an ill-fitting trocar and cannula, hitting a rib from failure to determine the exact direction of the rib and the intercostal space, breaking off a needle or producing by faulty technique a pneumothorax, so that the next man cannot possible tell what is inside. Yet all of these things happen.

The skin must be well sterilised with tincture of iodine. If the patient is very nervous or very young, ethyl chloride on the skin may be a desirable preliminary. Usually, however, I prefer to use the finest hypodermic needle for the skin puncture, changing it to a longer one when penetrating the intercostal space. The needle must be long enough to enter the pleural space without going up to the hilt. Otherwise it may break off and not be found again. If the needle is not perfectly sharp it must be sharpened on a small stone, which can be obtained from any surgical instrument maker. The point must be perfect, not like a fish-hook, as it is sometimes. The needle and the piston must both fit perfectly. No air must enter, for if it does it is impossible to be certain if air-bubbles are being drawn from the lung or the pleural cavity or are due to a faulty syringe. To test this put the end of the needle in the solution and pull back the piston forcibly. A vacuum should be formed and slowly fill with fluid; no air should enter. It is a severe test but the instrument should stand it. Fill the syringe with 2 per cent. sterile novocain[1] and put two fingers in the intercostal space to note its direction. Make a bleb of novocain with the fine needle inserted horizontally just under the epidermis. With the needle (or the larger needle) now vertical, push very slowly through the intercostal muscles, asking the patient to say when any sensation is felt. The intercostal muscles are devoid of sensation; when the patient begins to feel, the needle is approaching the nerve-endings of the parietal pleura. Now squirt out forcibly a good amount of novocain, then advance the needle a little further, asking if the patient feels anything. If the answer is "yes," give more novocain. If "no," go on. Soon the needle will enter either the pleural space or the lung or a solid area, and with gentle handling of the syringe the difference can usually be appreciated. Now withdraw the piston. If fluid is present, it will enter the syringe, and all that is necessary is done.

If nothing comes, it may be because there is nothing to come, or because there is pus too thick to go through the needle, or a new growth. Therefore a larger and longer needle is used. The patient is warned not to move and the new needle is pushed through the anæsthetised track; no pain whatsoever should be felt. If there is any pain, use more novocain; any amount can be used.

Sometimes it is very difficult to push the needle or the trocar and cannula through the skin. This means that the needle is not really sharp or that the shoulder of the trocar does not properly cover the end of the cannula. If owing to an emergency the needle cannot be sharpened or the end of the cannula bevelled on a stone, a small incision can be made in the skin after thorough infiltration by novocain. Alternatively the skin may be pinched up and the instrument pushed into the subcutaneous tissues horizontally to avoid all risk of entering the thoracic cavity suddenly and violently, and then held vertically and gently inserted. If a large instrument like a thoracoscope has to be inserted, it may be an actual advantage to make a preliminary incision down to the intercostal muscles to promote healing by first intention. But for ordinary exploration or aspiration this is crude technique and should be avoided. It frightens the patient and it leaves a scar. If an interlobar empyema or a malignant growth is suspected, it may be necessary to push the exploring needle three or four inches into the chest; this should not be in the least degree painful.

---

* A post-graduate lecture to old students of Charing Cross Hospital.

[1] This is best kept in stock with a little chloroform to prevent the growth of a fungus which otherwise usually appears; the solution can be boiled in a spoon just before use and the chloroform thus got rid of.

The occasions for puncture of the chest are as follows:

Exploratory Puncture.

Exploratory puncture is indicated: (1) if fluid is suspected and it is necessary *to know its nature*; (2) to distinguish between fluid, new growth, thickened pleura, or solid lung; and (3) sometimes if there is doubt whether a pneumothorax exists.

The signs of fluid are, as a rule, dullness, weak or absent breath sounds or bronchial breathing, an absence of adventitious sounds, weak or absent vocal resonance or *whispering pectoriloquy. There are two* popular fallacies. I am often told: (*a*) that fluid cannot be present because there is bronchial breathing; in the absence of adventitious sounds this is a sign—and a common sign—of fluid; (*b*) that pus cannot be present because there is no rise of temperature, but I have seen a streptococcal empyema of seven pints *with no* fever, and many other cases of non-febrile empyema. Even if the signs are not those of fluid, but pus is strongly suspected from the symptoms and the history, exploratory puncture should be performed. Carried out gently and properly I have never seen it do any harm.

Tapping a Serous Pleural Effusion.

A serous effusion should be explored: (1) if it is causing distress; (2) if it appears to be causing high fever; (3) if it does not begin to be absorbed after *three weeks' treatment*; (4) as a diagnostic measure to facilitate X ray examination, when replacement —a method to be described—will be necessary.

If these indications are not present no useful purpose is served by interference. *Pleural* effusion right up to the clavicle will often disappear entirely in three or four weeks.

There are several ways of removing serous fluid from the chest:—

1. The simplest method is *ordinary syphonage*. All that is needed is a needle, rubber tubing, and a bottle containing *some carbolic solution. The needle is put* into the chest with the tube attached, and the distal end is placed under the fluid in the bottle, which stands on a chair by the bedside. A cough will usually drive fluid out of the tube and syphonage will take place.

2. *Negative pressure aspirators.—Potain's aspirator* I find clumsy and unsatisfactory. I use a *Dieulafoy's aspirator* if simple syphonage is not possible. It is portable, can be used for replacement, and the tube is less likely to be blocked by lymph or, if blocked, can be cleared *by reversing the action.* Care must be taken not to exert too much force, as too high a negative pressure may be created in the pleural cavity, with unpleasant, alarming, dangerous, and even fatal results. These can all be prevented by the replacement method. I have an attachment so that the exploring syringe may be fixed straight on to the Dieulafoy needles or cannula. Sometimes at the psychological moment the washer fails to function. For this reason an all-metal apparatus may be preferable, but it prevents the operator from seeing what he is doing, *and the best method* is to use the *ordinary* apparatus and test it beforehand.

3. *Replacement by air or oxygen.*—The fluid, instead of being drawn off by the force of aspiration or of gravity, is replaced by sterile air or oxygen, so that a pneumothorax is left; this soon becomes absorbed, exerting steady and gentle traction on the lung, causing it to expand. This method avoids the dangers of aspiration: cough, distress, pain, hæmorrhage, pulmonary œdema, and sudden death, and all the fluid can be withdrawn *at one operation. Its practical* value may be illustrated by the following case:—

A youth of 19 contracted influenza. In a few days severe broncho-pneumonia developed, and within nine days typical signs of a large pleural effusion were manifest and he was desperately ill. I found the whole of the left side absolutely dull, and the heart considerably displaced to the right. Exploratory puncture revealed a reddish-brown purulent fluid. I aspirated with a Woulfe's bottle and a Higginson's syringe. About a pint of pus had been removed by gentle aspiration when the patient suddenly cried out in acute distress and became intensely cyanosed. I at once stopped aspiration, *disconnected the tube from the bottle*, and placed some cotton-wool lightly over its lumen. Air was sucked into the pleural cavity through the tube and the symptoms and the cyanosis were immediately relieved. I then aspirated *another pint of fluid, allowing a little air to enter the pleural* cavity from time to time in the manner described. The immediate relief of symptoms by the admission of air was dramatic. The pain of a high negative pressure in the *pleural cavity is not sufficiently emphasised in medical* literature. Occasionally, though fluid can be obtained on exploration, more can be withdrawn when the aspirating needle is inserted. This may be because the puncture has *been made too low and the diaphragm gets in the way* (the most likely reason), or that an adhesion has been encountered, or that the fluid is under great negative pressure. It is, therefore, important not to go too low. The best places *are just below the angle of the scapula or in the axillary* line in the fifth space, the patient being turned slightly towards the unaffected side. If there is a high negative pressure this will almost certainly be felt when using the *exploring* syringe and replacement will be necessary.

Aspiration of an Empyema.

In the ordinary slowly-evolving pneumococcal empyema the *usual method of resection* with drainage at the proper time, not too early and not too late, still remains the best. There are, however, two types of empyema that must never be treated by an open operation: (1) the tuberculous empyema, and (2) the acute streptococcal empyema, or a fulminating staphylococcal or pneumococcal empyema. In the *first case operation* will produce a doubly *infected* empyema and a persistent sinus. In the second case the patient will die. Aspiration, therefore, is the right treatment until it is safe to perform an open operation. A true tuberculous empyema (by this I mean an empyema the pus of which is sterile on culture but contains many tubercle bacilli, and not an empyema secondary to a spontaneous pneumothorax which has become infected by other organisms) should either be left alone or, if it is causing symptoms, replaced by air or oxygen; it may be necessary to replace it by 5 per cent. *gomenolised olive oil or paraffin oil.*

In dealing with an acute streptococcal (sometimes staphylococcal or fulminating pneumococcal) empyema appearing rapidly and early in the course of the illness, open operation must be avoided. The mediastinum has had no opportunity to become fixed, pressure changes on the contralateral side and mediastinal fluttering will occur, and the result will almost certainly prove fatal.

Aspiration must be employed. Occasionally negative pressure drainage may be used instead. The wound *must, however, be truly air-tight.* The following case may serve as an example:—

A nurse on duty in the wards complained for two days of malaise. On the third day she was obviously ill and was found to have a high temperature. Within two days of this, the left side of her chest was filled with fluid and she was desperately ill. Exploration revealed a thin pus which contained streptococci. By means of a syringe I aspirated *as much as* I could without causing any distress. For a week and more we aspirated daily and the patient began to improve a little. By this time the pus had become much thicker and it was deemed safe a few days later to make an intercostal incision and insert a small tube. She improved progressively, but the pleura had become thickened and the pleural space would not close, in spite of irrigation by Dakin's solution. Mr. Norman Lake therefore resected and decorticated the lung. This now expanded and a perfect recovery resulted. If early open operation had been performed in this case the patient, in my opinion, would inevitably have died.

Pneumothorax and Thoracoscopy.

Aspiration may also be needed for certain cases of high positive-pressure spontaneous pneumothorax, and in certain cases of hæmothorax after wounds or accident.

Artificial pneumothorax is becoming increasingly more common. The technique of inserting the needle for refills is the same as for exploration. The technique of induction, however, is more difficult and complicated, and in giving refills it is necessary to have a knowledge of the intrapleural pressures and their variations under different conditions.

By thoracoscopy is meant the passing of an optical instrument into the pleural cavity where a pneumothorax has previously been produced. It is done for diagnosis, to determine the nature of extra-pulmonary tumours and their relation of surrounding structures, and to determine the size, position, and nature of adhesions, with a view to their severence by the cautery if they are rendering an artificial pneumothorax inefficient by holding out the lung in a part where collapse is essential. With suitable local anæsthesia the passage of the instrument is painless. All possible care must be taken at the time and afterwards to limit the amount of surgical emphysema, which is apt to occur after prolonged thoracoscopy. With a short thoracoscopy there is no disturbance.

THE INFLUENCE OF

LIVER TREATMENT ON THE MORTALITY FROM PERNICIOUS ANÆMIA.

By PETER L. McKINLAY,* M.D., D.P.H.,

VISITING LECTURER, DIVISION OF EPIDEMIOLOGY AND VITAL STATISTICS, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE introduction of the treatment of pernicious anæmia by the Minot-Murphy method and its modifications has been followed in this country, as elsewhere, by its rapid extension, and the success attendant on this method of therapy has been confirmed in numerous reports since that time. All authorities seem to recognise in it a distinct advance in the therapeutic methods extended to patients suffering from this disease. The position now is thus comparable to that following the introduction in 1923 of insulin in the treatment of diabetes; and a review of the mortality from pernicious anæmia should possess a more than usual clinical interest.

Accurate study of the effects on mortality produced by a relatively sudden change in any factor likely to influence the course of mortality requires a clear picture of at least the more important features presented by the death-rates before that date. The object of the present note is, therefore, to resume briefly the events leading up to the introduction of this new treatment, to compare these with subsequent happenings, and to assess, if possible, in a quantitative manner the amount of improvement which has been effected by the change in therapeutic methods.

Review of the Data.

Age and Sex Distribution.—To give a general idea of the distribution of mortality by age and sex, the average death-rates by sex at certain broad age-groups for the six years 1921–26 are given in Table I. From this it will be noted that males experience at all ages a mortality about 20 per cent. lower than do females, but the difference is by no means constant at individual ages. In general the relative difference between the sexes diminishes with increasing age. Thus, at ages under 45 years the difference is about 40 per cent.; at 45 to 55, 18 per cent.; 55 to 65, 11 per cent.; and at ages over 65 years, only 2 or 3 per cent. Mortality in both sexes, however, shows an uninterrupted increase from the earliest ages up to the decennium 65 to 75, but in the final age-group again shows a slight decrease.

The *Secular Trend* of the death-rates from pernicious anæmia can be traced with accuracy only subsequent to 1920, the year in which it was first tabulated separately in the Annual Reports of the Registrar-General. Before that date deaths attributed to this disease were included in the group "Anæmia, chlorosis" (No. 58 of the international list), but, as T. H. C. Stevenson[1] has pointed out, these deaths contribute almost 90 per cent. to the total of this combined group, and the history of this cause of death prior to 1920 may, therefore, be inferred with some degree of accuracy from the records for that title. The chief interest at the moment, however, centres on the more recent events of the present decennium, and it is indeed fortunate that we possess reliable records, for an appreciable length of time, of the mortality attributed to this condition.

TABLE I.—*Mortality-rates in England and Wales by Age and Sex (1921–26).*

Age.	M.	F.
0—	4·9	7·8
25—	14·3	29·6
35—	39·7	69·4
45—	106·9	129·9
55—	226·1	252·8
65—	331·1	336·9
75 +	196·4	201·8
All ages	57·4	74·3

TABLE II.—*Trend of Mortality (Standardised Death-rates).*

Year.	M.	F.
1921	56·8	72·1
1922	62·0	71·9
1923	54·9	65·1
1924	55·8	69·5
1925	57·4	69·4
1926	58·4	74·7
1927	56·1	68·7
1928	37·2	48·0

M. = males; F. = females.

In Table II. are collected the standardised death-rates, separately for males and females, in each of the years from 1921 until 1928 (the latest records recently made available). These standardised rates of mortality, calculated by the direct method and using as "standard" the population at ages of the whole of England and Wales at the date of the 1921 Census, make allowance for the effect of the changes in the age constitution of the population which have taken place within the period under review. In both sexes, up to the year 1926, very little evidence of departure from a horizontal trend is noticeable. Between 1923 and 1926 there is an apparent slight tendency to increase both in the male and female death-rates, but these fluctuations are of no significance. That this is so has been verified in the following manner.

The average death-rates at ages for the whole period 1921–26 have been applied to the estimated age distribution of the population in each year of that period, and the expected were then compared with the actual deaths. The standard deviation of the difference between the actual number of deaths and the number which would have been recorded if the mortality at each age in any given year had been exactly the same as the average rates at ages for the whole period was taken as the square root of the expected number. In no year of the series up to 1926 do the deviations, either of the total deaths at all ages or of deaths at individual ages, exceed twice this figure.

It may, therefore, confidently be assumed that, in reference both to the total number and the age distribution of deaths from this disease, no significant change in either sex has taken place in the six, what may be termed "normal," years preceding the introduction of the new therapeutic methods.

Local Variations in Mortality.—In England and Wales the distribution of mortality from this cause is not given in the same detail as other, numerically more important, causes of death. For the available administrative subdivisions of the country the age-standardised rates of mortality, based on the experience of the years 1921–26 inclusive, for each sex, are given in Table III. The only point of interest here is the extremely low rate recorded in London. In the remaining three aggregates there is little difference either one from another or from the average for the country as a whole. The striking superiority of London is shared equally by the two sexes.

---

* Working for the Medical Research Council.

[1] Registrar-General's Statistical Review of England and Wales, 1926.

Seasonal Variations.—Stevenson [2] has already pointed out that there is a definite tendency for mortality from this cause to vary with season. The most significant feature of the seasonal distribution is the relatively low death-rate in both sexes in the third quarter and the exceptionally high rate in the winter months. In Table IV. are shown the proportions of the total deaths, uncorrected for differences in the number of days, in each quarter of the year for the period 1921–26. The autumn defect and winter excess are quite evident. (More detailed information on this aspect may be obtained in the successive Registrar-General's Annual Reports, in which are tabulated the number of deaths registered in each month of the year.)

Changes in Mortality in 1927 and 1928.

Table V. shows the male and female rates of mortality at separate and at all ages in these two years. Reference to this table and to the data previously collected in Tables I. and II. brings out the following features of interest. Compared with the average experience of 1921–26, there has been in 1927 a reduction in mortality, both in males and females, in some of the age-groups, but the total improvement, obviously small, is counterbalanced by increased mortality in the remaining periods of life. In the succeeding year, 1928, diminished mortality is a feature of every age-group, with the possible exception of the numerically unimportant period 0–25 years.

TABLE V.—*Rates of Mortality by Age and Sex in 1927 and 1928.*

Age.	Males.		Females.	
	1927.	1928.	1927.	1928.
0—	4·1	4·9	7·0	6·3
25—	12·7	12·1	26·8	16·8
35—	32·1	16·7	60·1	38·0
45—	83·0	53·4	132·1	71·9
55—	230·3	126·0	242·0	177·8
65—	309·7	269·9	353·4	280·5
75 + ...	230·3	187·4	234·3	186·9
All ages standardised	56·1	37·3	68·7	48·0

The statistical significance to be attached to these differences has been tested in a manner similar to that previously employed. The average death-rates at ages for 1921–26 are applied to the estimated population at these ages in 1927 and 1928, and thus are obtained at each age the expected number of deaths. The difference between the actual (A) and the expected (E) deaths compared with the standard deviation of the difference ($\sqrt{E}$) provides us with the required measure of reliability. If the ratio $(A \sim E)/\sqrt{E}$ does not exceed the value 2·0, one is not justified in considering the difference a real one—it might reasonably be looked upon as a random fluctuation. In the year 1927 (the figures have not been tabulated) the actually recorded deaths are fewer, though insignificantly so, than the numbers we should have expected on the basis of the 1921–26 experience, and at individual age periods, also, any tendencies towards improvement, with the one exception—namely, in males aged 45 to 55 years—might well be attributed to chance. The experience of this year, therefore, does not seem to justify any inference as to the effects of treatment on mortality. For the more interesting year, 1928, the comparison between fact and expectation is effected in Table VI. In this year, if the death-rates prevailing in 1921–26 had continued, the number of deaths which would have occurred exceed those actually recorded by as much as 55·3 per cent. in males and 45·4 per cent. in females. At individual ages, moreover, there are only four instances—namely, at ages 0–25 and 25–35 in males, and 0–25 and 75 and over in females—in which the divergence of actual from expected does not exceed the required standard of significance. It is quite certain, then, that in 1928 there was a significant reduction in the number of deaths from this disease in both sexes, although the relative amount of improvement is not constant at different ages. The greatest amelioration in males is at ages between 35 and 65 years and in females at 25 to 55 years, where the recorded deaths form only about half of what would have been recorded had the 1921–26 rates of mortality prevailed. At other ages the improvement is not nearly so great, the recorded in proportion to expected deaths being 84 per cent. in males over 65 years, and 78 per cent. in females over 55 years.

TABLE VI.—*Comparison of Actual and Expected Deaths in 1928.*

Age.	Males.		Females.	
	Actual.	Expected.	Actual.	Expected.
0—	42	41·7	53	65·9
25—	34	40·3	51	96·9
35—	41	97·6	111	202·9
45—	123	244·3	186	335·9
55—	211	378·5	330	469·1
65—	238	286·6	297	350·7
75 + ...	50	58·7	87	93·9
Total	739	1147·7	1116	1621·3

It seems reasonably certain, therefore, that, although the returns of 1927 do not provide us with much evidence of reaction of mortality to the institution of the new methods of treatment, there is ample evidence in the latest returns of correlation between these two factors.

We may note further, without actually recording the tabular matter, that the main subdivisions of the country, treated in a similar manner, provide exactly similar results—namely, no substantial reduction in 1927 but great improvement in the succeeding year. There is, too, a suggestion that the improvement has been greatest in London, somewhat less in county boroughs, and still less in the smaller urban districts. Rural districts show the same rate of decline as do county boroughs. These remarks apply equally to both males and females.

Expected and Actual Deaths by Season.

This other important feature must be mentioned. Since, as has been shown, the mortality from this cause exhibits definite relation to season, it was considered advisable to compare the records of the two years 1927–28 in somewhat greater detail. The expected numbers of deaths in males and females in these two years were distributed to the four quarters of each year in the same proportions as had already been found for 1921–26, and these were then compared with the seasonal experience which was actually recorded in these two years. It will be seen from the data compiled in Table VII. that in males the actual deaths exceeded the expected in the first and third quarters of 1927, that in the second quarter these were practically identical (the slight difference is statistically quite insignificant), whereas in the fourth quarter the actual deaths amounted only to 79 per cent. of what would have been recorded had conditions remained as in 1921–26. Compared with the standard error involved, this is a numerically important deficit. In each of the four seasons of 1928 we find the actual deaths well in defect of the expected, and, what is perhaps of greater significance, the relative difference gradually increases throughout the year. Thus, in the first quarter the actual deaths formed only 78 per cent. of the expected; in the second quarter, 65 per cent.; in the third, 64 per cent.; while in the last quarter for which records are available the ratio was still further reduced to 51 per cent. of the numbers anticipated. This steadily increasing divergence between fact and expectation constitutes probably a point of fundamental importance in the records of mortality statistics.

---

[2] Ibid., 1925.

In females a somewhat similar encouraging trend is manifest, except that the records of the year 1927 do not at all suggest the intervention of any agency favourable to a declining death-rate. Thus, although there is a statistically significant discrepancy in the second quarter of this year, no such difference is apparent in the remainder of the year, in which actual and theoretical deaths almost exactly correspond. In the succeeding year, however, no doubt can possibly exist as to the significance of the general tendency. In the first quarter the deaths which occurred formed only 74 per cent. of what we should have predicted; in the second, 70 per cent.; in the third, 66 per cent.; and, finally, in the fourth, 65 per cent.

Such a tendency is exactly what would be expected from the extensive and extending use of a beneficial therapeutic agent.

Summary and Conclusions.

The inferences suggested by the foregoing analysis of the mortality returns of pernicious anæmia in England and Wales may be resumed briefly as follows. For the six years immediately preceding the introduction of the new dietetic treatment of this disease the rates of mortality in both sexes pursued a course which was practically horizontal, the age and sex distributions of the deaths at the same time showing no important changes. In 1927 there was a slight tendency towards improvement apparent in males and specially affecting the returns of the last three months of the year; but, taken in conjunction with the findings for the mortality among females, it may fairly be said that the evidence of significant change which can be derived from these statistics is not at all convincing. In the succeeding year a very definite decline in mortality took place—a reduction of some 915 deaths over expectancy, affecting both sexes, limited chiefly to young adult and middle ages, beginning early in the year and consistently increasing towards its close; greater in London than elsewhere and occurring in the absence, so far as we are at present aware, of change in any factor liable to affect the course of mortality other than the method of treatment. The general inference seems obvious. That there has been a definite lag between the institution of the new treatment and the response of the death-rate is not at all surprising. The whole of the evidence is consistent with the view of causal association between the two factors and, judging from the course of mortality in the comparatively short period since the institution of specific therapy, it would seem safe to predict that extension of the treatment to a still larger proportion of patients suffering from the disease will be reflected in further decline in the mortality attributed to this cause.

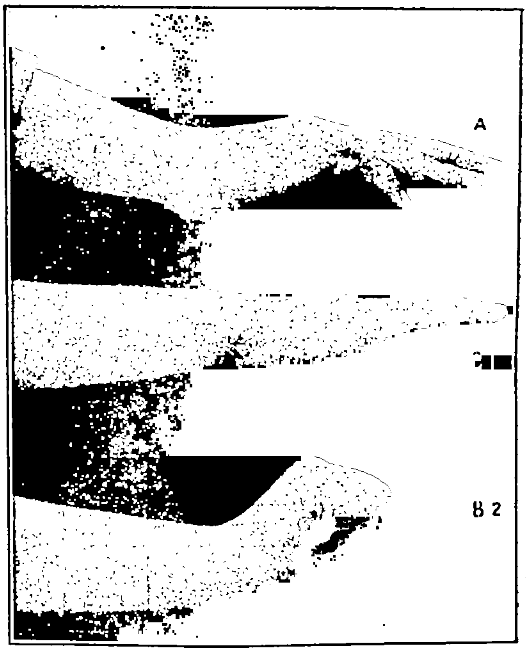
A CASE OF

HEREDITARY CONTRACTURE OF THE LITTLE FINGERS (KAMPTODACTYLY).

BY ALAN H. TODD, M.S. LOND., F.R.C.S. ENG.,
ORTHOPÆDIC SURGEON TO THE CROYDON GENERAL HOSPITAL, THE WEST KENT GENERAL HOSPITAL, AND THE ALEXANDRA HOSPITAL FOR HIP DISEASE, SWANLEY; LATE SURGICAL SPECIALIST TO THE R.A.F.

THE diagnosis of this condition presents no difficulty, even when the patient happens to be an adult. There is always a history of the contracture having been present ever since infancy, undergoing very little change if left untreated; and in some cases its congenital character is emphasised by the presence of other congenital abnormalities, such as club-foot, hare-lip, hammer-toe, &c. As a rule both hands are affected more or less equally. Females are said to be more liable to the condition than are males. The type of contracture is quite characteristic; the metacarpophalangeal joint is hyperextended, the proximal interphalangeal joint is flexed (usually to about a right angle), and the distal joint is extended or tends to be extended. In many cases, but not in all, the contracted proximal interphalangeal joint is stiff; no movement can be obtained at it, actively or passively; but the patients learn to accommodate themselves to this, having never known anything different, and it seems to handicap them little, if at all; I know, for instance, of a brilliant surgeon whose dexterity as an operator is certainly not impaired by it. The stiffness of the joint seems to be entirely due to changes in the soft parts; radiograms never show any abnormality. The palmar fascia is never affected; this is one of the most important points of distinction, in adult cases, from Dupuytren's contracture. The principal contracture seems to be, primarily, in the capsule of the joint on its flexor aspect; in this respect there is a close resemblance to congenital contracture of the knees, whilst the stiffness of the joints is

FIG. 1.



The hand in a case of kamptodactyly before treatment (A) and after treatment (B).

reminiscent of many cases of congenital contracture of the shoulder-joints, though the latter class sometimes show radiographic abnormalities.

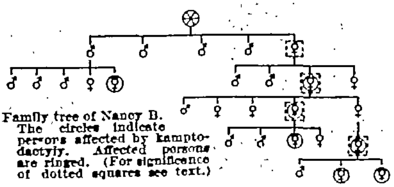
As in all congenital deformities, there is a marked tendency to relapse after treatment by stretching with splints. But, in the early stages of the condition, there is no difficulty in straightening the fingers by means of simple palmar splints.

In the present case the patient was a female child, 14 months old, and a strip of aluminium, ¼ inch wide, bent to fit the little finger and palm, was affixed by means of a continuous spiral of zinc oxide strapping, a tiny pad of white felt being placed on top of the projecting joint and beneath the tip of the middle phalanx. By gradually straightening the splint as the contracture yielded, the finger was straightened in the course of six weeks. The splint is now being applied intermittently to prevent any recurrence of the deformity, and it is hoped, by keeping the child under observation, to ensure a permanent cure.

The photographs (Fig. 1) show another case, that of a girl aged 12, in whom the same method brought about complete correction in four months. In both cases flexion and extension of the little fingers are full, painless, and normally powerful.

The mother of the younger child, Nancy B. (who was under my care as an out-patient at Croydon General Hospital), took a particularly intelligent interest in the condition, and compiled a family tree (Fig. 2), showing which members of the family had been affected, out of the total number, in six generations; it is believed that the condition was present in earlier generations, but no exact information is available about these. The tree, as presented, is probably pretty accurate, since the mother went to much trouble to obtain corroborative evidence from various relatives. It is interesting to note that, in each generation, the firstborn child (shown on the right of the tree) escaped. It may be noted that there was no consanguinity between any of the fathers and mothers, and that there were no cases of similarly affected persons marrying.

FIG. 2.



Family tree of Nancy B. The circles indicate persons affected by kamptodactyly. Affected persons are ringed. (For significance of dotted squares see text.)

Observations by Prof. Wells.

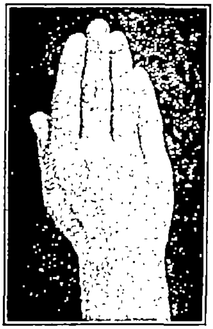
The family tree was submitted to Prof. G. P. Wells, of the Department of Zoology, University College, London, who examined it with Prof. Watson and Mr. Palmer, and kindly made the following commentary upon it.

"It is not by any means easy to get a simple story out of it, but we would like to make the following suggestions. Assuming the condition to be due to a single Mendelian gene, it must be recessive, because it runs through the first generation without showing itself. If this be true, the character could never appear again unless one of the people in whom it was carried happened to marry another who also carried the gene. Now this must have happened no fewer than five times, all the people indicated by dotted squares having married other heterozygotes—which is at first sight a very improbable proposition! It would very greatly increase the value of the data if information could be got as to the other families which married into this one. In the table as it stands only one parent of each generation is accounted for, while in considering the results of any pairing one naturally wants information about both. Thus it would be interesting to know whether the partners of all the people ringed with dotted squares came from unrelated families without any trace of a similar deformity, or whether there is any evidence of inbreeding (such as cousin marriages) in the pedigree. The latter event would, of course, diminish the improbability of the ringed people having married other heterozygotes.

"In the matter of the firstborn not being affected, this is, in our opinion, a chance result. It is hard to see how such a selective effect could come about, and (as the number of firstborn in the table is only 6 out of 26 individuals) the odds against such a distribution are not very great. What is rather more remarkable is that only females are affected, although apparently the gene can be transmitted through males. But here again it is difficult to judge whether the number of individuals recorded is sufficient to warrant the inclusion of extra factors (such as a sex-linked modifying gene) *to explain* the restriction."

As far as could be ascertained, there was in fact no history of any similar affection in any of the persons marrying into the affected family, and there was certainly no intermarrying.

FIG. 3.



The hand in a case of klinodactyly.

Prof. Crew's Notes.

Upon Prof. Wells's suggestion, the pedigree was also sent to Prof. F. A. E. Crew, of the Animal Breeding Research Department of the University of Edinburgh, who very kindly sent me the following notes upon the case, and references to the literature:—

"The condition which you describe has been recorded by several people, but always rather imperfectly. Your case is an instance of a sex-limited or sex-controlled dominant which, for reasons unknown, is not always expressed. I am assuming, of course, that the non-appearance of the condition in males is significant, and that it appears in females because of their different physiology (sex controlled). It would be interesting to make a very complete examination of the grandmother of the last generation in your family tree; it seems somewhat strange that she did not exhibit some degree of the condition. I am sorry that one cannot give a simpler explanation, but that seems always to be so in the case of the human. The expression of a hereditary character seems to be conditioned by many forces, of which one as yet knows nothing.

"So-called 'klinodactyly' (see Fig. 3) is a condition where the end joint of the little finger (and frequently the ring finger) is inclined sideways towards the middle finger, and is stiff. Mode of inheritance is dominant.[1] This bending to the side occurs very often as a consequence of brachyphalangy of single fingers. So-called 'kamptodactyly' is a condition where the little finger (and frequently the ring finger) is bent forward and is stiff. Goldflam[2] reports on a family where, in three generations, 26 persons were affected.

"Many hereditary disturbances of muscular function and pathological muscular structure are known. No case of dominancy has been observed. Most cases are to be classed as muscular dystrophies. It is not infrequent for sex-linked recessive 'Anlagen' of muscular dystrophy to appear. Lenz[3] the relative difference gradually increases throughout the year. Thus, in the first quarter the actual deaths formed only 78 per cent. of the expected; in the second quarter, 65 per cent.; in the third, 64 per cent.; while in the last quarter for which records are available the ratio was still further reduced to 51 per cent. of the numbers anticipated. This steadily increasing divergence between fact and expectation constitutes probably a point of fundamental importance in the records of mortality statistics.

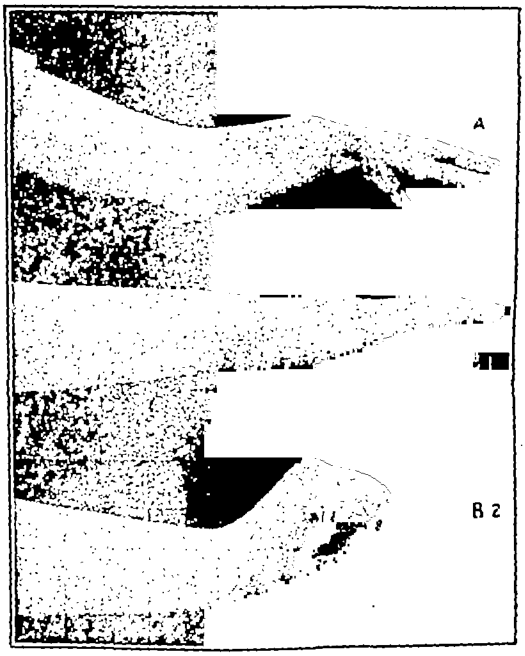
A CASE OF

HEREDITARY CONTRACTURE OF THE LITTLE FINGERS (KAMPTODACTYLY).

BY ALAN H. TODD, M.S. LOND., F.R.C.S. ENG.,
ORTHOPÆDIC SURGEON TO THE CROYDON GENERAL HOSPITAL, THE WEST KENT GENERAL HOSPITAL, AND THE ALEXANDRA HOSPITAL FOR HIP DISEASE, SWANLEY; LATE SURGICAL SPECIALIST TO THE R.A.F.

THE diagnosis of this condition presents no difficulty, even when the patient happens to be an adult. There is always a history of the contracture having been present ever since infancy, undergoing very little change if left untreated; and in some cases its congenital character is emphasised by the presence of other congenital abnormalities, such as club-foot, hare-lip, hammer-toe, &c. As a rule both hands are affected more or less equally. Females are said to be more liable to the condition than are males. The principal contracture seems to be, primarily, in the capsule of the joint on its flexor aspect; in this respect there is a close resemblance to congenital contracture of the knees, whilst the stiffness of the joints is

FIG. 1.



The hand in a case of kamptodactyly before treatment (A) and after treatment (B).

board. Microscopic examination of the sputum showed no tubercle bacilli but there were many cocci arranged in chains, together with an enormous number of pus cells. A skiagram taken shortly after admission showed a dense homogeneous opaque shadow with horizontal upper margin at the level of the fourth rib in front, the shadow merging homogeneously with the cardiac and diaphragm shadows. Above and to the outer side was a clear pocket between the third and fourth ribs, bounded externally by the chest wall and with its inner margin concave outwards midway between the chest wall and mediastinum. Above and to the inner side of this clear area was a shadow of moderate and uneven density, though much less dense than the basal shadow, extending to the apex of the lung. The heart was not apparently displaced to the left. A provisional diagnosis was made of partial pneumothorax due to perforation of bronchus in a case of empyema; subsequent investigation proved this to be correct. A series of leucocyte counts gave an average of 17,500, and a detailed examination of the purulent expectoration was made by Dr. A. F. O. Davey, of the Public Health Laboratory, Manchester, who reported as follows: "Microscopic examination shows pus cells and numerous organisms, chiefly streptococci, some of which occur in long chains. Blood-agar plates inoculated with the material produce a profuse growth, chiefly of hæmolytic streptococci. Two animals were inoculated on Sept. 12th and both died on the following day. Films from the heart blood showed streptococci and on cultivation hæmolytic streptococci were again obtained."

The subsequent history is interesting. The sputum, which on admission had been very profuse, gradually became less and the lad's condition improved. On Sept. 5th he complained of headache and pain in the right chest. The following day his temperature rose to 100·6° and he coughed up half a pint of very thick purulent material. He felt better after this and his temperature became normal. The physical signs in the right lung about this time were: defective movement; tactile vocal fremitus present all over; dullness on percussion, especially over the lower lobe; some breath sounds with a few crepitations over the upper lobe; no breath sounds over the lower lobe. A second skiagram now showed no evidence of the air-pocket, the whole of the right side of the chest appearing as a dense opacity. He was discharged from hospital on Sept. 26th, his condition having greatly improved since admission.

The accidental perforation of a bronchus was fortunate for the patient in that it provided an exit for the pus in a case of empyema hitherto unrecognised. Considering the marked improvement in his condition after the evacuation of the pus, resection of rib was deemed unnecessary, as the prognosis in such cases is said to be fairly good.

I have to thank my colleagues, Dr. C. W. Laird and Dr. G. B. Charnock, for providing me with the opportunity of investigating this case, and the Central Tuberculosis Officer (Dr. Lissant Cox) for permission to publish it.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

THE TRAINING OF MIDWIVES.

A MEETING of this Section took place on Nov. 15th, Dr. ARTHUR E. GILES, the President, being in the chair.

Dr. HERBERT SPENCER, in introducing a discussion on the Report of the Departmental Committee on the Training of Midwives,[1] pointed out that only one of the 12 members of the Committee was an obstetrician. That one member, Dr. J. S. Fairbairn, and Mrs. Richmond had dissociated themselves from those recommendations which involved the splitting up of the functions hitherto performed by the Central Midwives Board. Dr. Fairbairn and Mrs. Richmond urged that no such momentous changes should be made without full and open discussion not only by the midwives, teachers, teaching schools, and other interested parties in England, but also by the corresponding Boards in Scotland and both Divisions of Ireland, with whom there had hitherto been complete reciprocity. With most of the rest of the report he assumed that members of the Section would agree, especially with the recommendation for preferential treatment of medical students over midwives in the allocation of cases in the medical schools, and with the comment that a large amount of valuable clinical material was used by midwives who did not intend to practise. Parts 1 and 5 of the report dealing with the historical aspect of the subject and with administration were those which most nearly concerned the Section of Obstetrics, and these merited the most earnest consideration. Dr. Spencer said he thought the report of the Departmental Committee might well have pointed out that it was to the persistent efforts of the Obstetrical Society of London that the Midwives Act of 1902 was due. He believed that the Section would agree that the Central Midwives Board had performed its duties well, and that the Section would not think the duties could properly be carried out by a Ministry of Health, whose treatment of the panel doctors was characterised by the Lord Chief Justice of England as pure despotism.

Criticism of Administrative Proposals.

Dr. T. WATTS EDEN said that the report of this Committee contained much with which the Section of Obstetrics and obstetric teachers would find themselves in agreement. It was to the administrative proposals that serious exception was taken. The principle upon which the practice of midwifery had been carried on in this country since the first Midwives Act was passed was, that their affairs were dealt with by a statutory authority appointed for the purpose, into whose hands were placed all matters concerned with the education and training and professional conduct of midwives. Dr. Eden thought this was a very sound principle, from which, however, the Departmental Committee proposed an entire departure. Upon the statutory authority the three classes mostly concerned—obstetric teachers, general practitioners, and medical officers of health—were all represented, so that the affairs of the midwives were in the hands of those who knew something about the matter. He would not say that the constitution of the Central Midwives Board was an ideal one; it might have been more ideally representative of the classes chiefly interested, and it might have been given wider powers, but within the limits imposed upon it the Board did very excellent work. Obstetricians were now asked to consent to depriving this statutory authority of its most important functions, to the removal of responsibility for the training and education of midwives out of their hands. It was proposed this responsibility should be vested in the Ministry of Health, which should have the assistance of something which was called an advisory committee. The experience of himself and his colleagues was that advisory committees of Government departments were not allowed to do very much. When the Ministry of Health was constituted an advisory medical committee was appointed, with Sir Bertrand Dawson (now Lord Dawson) as its chairman, and he believed that body had never been given any serious work to do at all. When medical subjects came up for inquiry the practice of the Ministry was to make its arrangements and appoint its committees of inquiry independently of its own advisory committee; and Dr. Eden expected that if this scheme should go through, the advisory committee on midwifery would meet with much the same fate. Even if it were asked for its opinion at all the Ministry would not necessarily accept the advice given—and the power would be entirely in the hands of the Minister. This matter must also be considered in connexion with the scheme set out in the report of the Departmental Committee for the formation of a national maternity service,

---

[1] See THE LANCET, Sept. 28th, pp. 669 and 680.

It was contemplated by this Committee that when their scheme was put into operation four-fifths of the confinements of the country would be carried out by midwives who would be paid for their services under the Insurance Act by the local authority, and would consequently be, to a great extent, under the control of the Ministry of Health. The result would be that the practice of midwifery, roughly speaking, would pass under the control of a Government department instead of being, as it was now, in the hands of the profession, guided by the statutory authority. He hoped the Section would agree that such a change could not be carried through without great detriment to the teaching and practice of midwifery.

One of the important duties of the Central Midwives Board was the inspection and approval of the institutions in which midwives were trained. It was true that their power with regard to inspection had been seriously interfered with by the action of the Ministry of Health, because when the poor-law institutions began to train midwives the Ministry of Health said: "You cannot inspect these institutions; they are Government institutions, and we will inspect them ourselves." But the Ministry of Health had no inspectors on its staff capable of inquiring into the efficiency of the methods of instruction given and the suitability of the general system on which the institution was worked. In the resolution which would be submitted to this meeting it would be suggested that the transference of the education and training of midwives and the inspection of their training schools from the ad hoc authority to a Government department was a retrograde step, and that the control and education of midwives and their professional conduct and the bearing of the institutions in which they were trained should still remain in the hands of the authority appointed for the purpose. The Section might consider that that authority should be a larger and more influential body than the Central Midwives Board, that it should be given greater powers, that the majority on that authority should be those who knew, from the practical point of view, what the practice of midwifery was, and that it should be strengthened by the addition of others whose experience of affairs generally and business would be an advantage from the point of view of organisation. But an ad hoc authority there must be if anything like liberty in this matter was to be preserved, either to doctors or to midwives. He did not doubt that, if this scheme should go through, there would be produced before long another scheme by which doctors who practised midwifery under the Insurance Act would also become officials in the Ministry of Health and be paid by the State, so that thus the hole practice of midwifery—except the fractional rt concerned with those to whom expense was no ject—would pass into the hands of the Ministry, ist as the treatment of infectious diseases and tuberculous diseases had done. If such a movement as the present one was likely to succeed, the sooner the profession made its voice heard in opposition the better; and the Section was being asked on this occasion to take the first step—it was hoped it would not be by any means the last step—in making it clear to the Government that such proposals as the Departmental Committee had put forward were totally unacceptable.

The Teacher's Standpoint.

Prof. L. **McIlroy** spoke as a teacher. If 75 per cent. of the midwifery cases of the country were conducted by midwives under the control of the Ministry of Health, who, she asked, would look after the remaining 25 per cent? Would they be looked after by the specialists only, or by the general practitioners? Teachers were not out to train specialists after graduation; they were teaching the future general practitioner, and if practitioners were not going to do midwifery it was time the medical schools set about saving the money spent on their education in obstetrics. She thought it a great pity that up to the present time this Section had been so involved in the maelstrom of scientific work that it had stood aside and had not taken any active part in this controversy. It was a serious matter from the point of view of the teachers and that of practitioners. She wondered what type of person would exercise control in this matter at the Ministry. It might be someone who knew the administrative machinery, but the difficulties of the doctor and midwife could not be understood except by one who was living the life of an obstetrician. If the advice of the general practitioner and of the teacher were shut out, little would be left. The midwife service had been efficient because midwives had had the advantage of the training and the teaching of specialists. She believed that the retention of the Central Midwives Board would make for a better service for the country than would any Government organisation.

A Member of the Departmental Committee.

Dr. J. S. **Fairbairn** said in an organ of the lay press Lord Hewart had stated: "The conclusion is irresistible that it is manifestly the offspring of a well-thought-out plan the object and effect of which were to clothe the Department with despotic powers over midwives and midwifery generally." The word "Departmental" was the clue to the whole thing. The Department suggested that the Committee was required, the Department determined its composition and its chairman, and those who were to be members of it were not told who their colleagues were to be. On the whole, it was an almost comical body from which to expect a sound opinion on midwives. The administrative side had been in the majority on the Departmental Committee which, unlike a Royal Commission, did not publish its evidence in full. Much of what was tendered was not within the proper meaning of evidence. Only one midwife had sat on the Committee, and she could scarcely be said to represent practising midwives. He had had the feeling throughout the sittings that he was in an antipathetic atmosphere, hostile to the Central Midwives Board, and that the case had been prejudged. The proposal supposed to emanate from the London County Council was apparently the voice of the medical officer of health of that body who had never had to do with midwives. Dr. Fairbairn agreed with Dr. Eden's views about inspection by the Ministry of Health. The Central Midwives Board was not allowed to look inside the poor-law institutions. In some of these hospitals there were, perhaps, 30 confinements in a year, and since it was desired that the nurses should obtain their certificates in midwifery, such nurses were taken from their duties in other wards and were summoned to be present at the confinement in order to be signed up. This was termed training in obstetrics. He felt that these recommendations were the thin end of the wedge, and that sooner or later the medical profession would be involved in similar proposals in so far as the insured women were concerned. He hoped this Section would make its protest.

Discussion.

Dr. W. H. F. **Oxley** (Chairman of the Maternal Mortality Committee) said that questions of the kind under discussion profoundly affected maternal mortality, and he felt that his Committee would consider evidence tendered by this Section on the point, as they were anxious to reach conclusions of real value.

Dr. **James Young** expressed the hope that Dr. Oxley, having heard the discussion, would place the justice of the cause before his Committee. The debate left little room for doubt that the efforts to bring about this change were misdirected. The discussion, and other statements which had been made, should do much to convince those in authority that there was reason for giving the Central Midwives Board a larger representation than ever, and that the responsibility for the management of the affairs of this large professional body should be far more in their own hands. Then there would be nothing to prevent the raising of the standard of midwives.

The PRESIDENT wished it to be clearly understood that the Section was not discussing this matter in any spirit of trade-unionism—i.e., with the idea that the members were seeking to serve the interests of the medical profession—many of whom would be glad to be relieved of the most arduous and worst-paid part of their work. The prevailing feeling of the Section, he was sure, was that if the practice of midwifery were removed from the supervision of medical men, and placed in the hands of a Government department, the well-being of lying-in women and of new-born children would be seriously impaired and imperilled. It was on that broad and important ground, that of the public health, that he personally felt so strongly that the resolution to be submitted should be supported. If carried, the resolution would pass to the Council of the Society, and be forwarded to the proper quarter.

A Resolution.

The resolution, which was carried unanimously, was as follows:—

> "The Section of Obstetrics and Gynæcology of the Royal Society of Medicine having discussed the Report of the Departmental Committee on the Training and Employment of Midwives is of opinion:—
>
> "1. That the responsibility for the education and training of midwives, including approval and inspection of training schools, should be retained in the hands of an independent body appointed for the purpose and consisting largely of those who are or who have been engaged in the practice of midwifery.
>
> "2. That the proposal contained in the Report to limit the power of the Central Midwives Board and to give the Minister of Health the sole responsibility of approving and inspecting training institutions and teachers, and of laying down the curriculum of training, would, if adopted, be prejudicial to the teaching and practice of midwifery in this country.
>
> "3. That the Departmental Committee responsible for the recommendations to which we take exception was not a representative body inasmuch it contained only one member out of thirteen who had practical knowledge both of the teaching and practice of midwifery, and this member dissented from the main recommendations of the Committee."

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

A QUARTERLY meeting of this association was held in London on Nov. 6th, with Dr. NATHAN RAW, the President, in the chair. A paper on some experiments with

Suggestion and Association Tests in the Feeble-minded.

was read by Dr. T. SAXTY GOOD, who pointed out that suggestion and suggestibility were two different processes. By suggestion was meant the sum total of (1) stimuli received by sight, hearing, taste, smell, touch (designated external stimuli), and (2) from the autonomic system, which did not enter consciousness in health, except as urges connected with primitive instincts. This could be termed auto-suggestion. The condition of the body called illness was a condition in which the sympathetic system became conscious. Feeble-mindedness was, psychologically, a failure of repression and a falling to a lower type of mind. The results of suggestion and association tests he had performed could be translated in practice as meaning that the dominant parent who had been complacent to the child would cause it to grow up positive to suggestion, whereas a repressive dominant parent or prototype would produce a negative reaction in the child.

Dr. GEOFFREY SHERA read a paper on

Bacillus Acidophilus in Mental Patients.

During 18 months, he said, he had examined the stools of cases admitted to the East Sussex Mental Hospital within a week of their arrival. Among 53 mental cases the reaction of the stool was alkaline in 80 per cent., neutral in 10 per cent., and acid in 10 per cent; 30 per cent. showed abnormal coliform bacilli, while 69·1 per cent. showed abnormal streptococci. *Bacillus acidophilus* was obtained in pure culture within 72 hours in 9·4 per cent.; in 41·5 per cent. the appearance of this organism was delayed more than 72 hours. Abnormal aerobes were present in 20·6 per cent. of the cases; non-hæmolytic staphylococci in 38·9 per cent., and hæmolytic in 7·5 per cent.; non-hæmolytic streptococci in 43·1 per cent. and hæmolytic in 54·3 per cent. Constipation, said Dr. Shera, was an accompaniment of *B. acidophilus* deficiency, and in general practice this deficiency was usually remedied by the administration of *acidophilus* milk or emulsion. Constipation was the rule in mental patients, and aperients were needed. Eighty-one per cent. of mental patients showed deficiency of *acidophilus*, so that it was reasonable to attribute at least part of the prevailing intestinal toxæmia in them to this. The weakness of the intestinal defensive mechanism was obvious in these patients. Warren Crowe had evolved a method of pathogenic selection, and this made the remedy more hopeful.

Dr. B. H. SHAW referred to his own attempts in this direction, giving a prepared meal each night. The meal was so unpalatable that after a short time he had to desist.

Dr. M. STEWART said that the theory that mental disease could be caused by the condition Dr. Shera described had come in for a good deal of criticism. The reason this subject had been worked at so persistently was obvious. When mental patients arrived they clearly had bowel poisoning, loaded intestine, foul tongue, bad breath, sallow features, and constipation, sometimes alternating with diarrhœa. There was also an increase in coliform bacteria, and a lessened quantity of those of the *acidophilus* group.

Dr. A. W. PETRIE agreed about the number of fallacies encountered in these investigations. Those who had done the plating of fæces had been struck by the abnormal plates of mental patients, especially in the increase of the non-lactose fermenters or the late lactose fermenters. In mental patients there had generally been a good deal of disease which had upset the flora. He suggested that taking the fæces for examination on the first arrival of the patients meant taking them at a time of temporary upset, and when they were in a particularly toxic state owing to neglect. He had sometimes succeeded in altering the flora picture of patients but usually he had not noted any coincident mental benefit. He would like to know what kinds of mental conditions were dealt with by Dr. Shera. The paranoid type would probably tend to have a normal intestinal flora, whereas the agitated or stuporose melancholic would have one that was more abnormal. On the whole, treatment along these lines had been, in his hands, rather disappointing.—Dr. W. F. MENZIES said that in Dr. Shera's long and painstaking work little was stated about the mental condition of the patients who were treated. Similar treatment based on earlier researches of asylum workers had not, he thought, brought about mental improvement as a rule.—Dr. G. W. T. H. FLEMING said that five years ago two Americans had shown that the liver had very little power of detoxifying histamine. He thought a good deal of work required to be done on those lines.

Dr. SHERA, in his reply, said his practice was to ask for a loose motion for the examination, but if the patient was constipated an aperient was given overnight. With the glucose broth method, however, he was indifferent about the type of stool; the broth would show the bacillus if it were there. He did not claim that *acidophilus* therapy would necessarily eliminate the abnormal coliforms, but it was sound practice to try to re-establish that bacillus in the intestine. Prof. Embleton had told him of another way of eliminating the coliforms—namely, by giving an antivirus by mouth. Progress had not yet reached the stage when one could classify the flora according to the mental state. He reminded the meeting that any milk which was sour was not necessarily *acidophilus* milk.

HUNTERIAN SOCIETY.

MEMBERS of the Medico-Legal Society were invited to attend a meeting of this Society which was held on Nov. 18th. The President, Dr. E. C. YOUNG, occupied the chair, and Lord HOWE opened a discussion on

THE DOCTOR AND THE MOTORIST.

Quoting from Table D of the first report of the Royal Commission on Transport, he stated that over 6000 people had lost their lives on the roads of this country in 1928. It was quite possible to reduce this figure by at least 10 per cent., and it was imperative that some action should be taken at once. The speed-limit might be made a little higher, but if it were abolished the police would be compelled to prosecute for driving to the public danger. To be justly tried the cases would have to be heard at great length, and the work of the courts would be much increased. Moreover, he doubted whether the present courts were sufficiently well equipped to deal with this most difficult issue, and recommended—in case the speed-limit were removed—special traffic courts, analogous to the commercial court, assisted by technical assessors.

The six most prolific causes of an accident were, he said, all preventable: excessive speed, inattention, confusion or lack of judgment, failure to exercise care at road junctions, improper cutting in or out, failure to keep to the proper side of the road, and inexperience. A competence test alone would enormously reduce the casualties under these six headings. This test might be voluntary and conducted by local panels, who would issue graded certificates. The grade of a driver's certificate, or its absence, would be taken into account by the court and insurance companies would favour the driver with the good certificate, so that its possession would be a practical necessity. The allegation that the skilled driver was the cause of accidents was not borne out by Table D.

Dr. E. B. TURNER held that if the appalling tale of accidents was to be reduced it was vitally necessary to ensure by some form of test that drivers were physically fit. Among physical conditions which rendered a driver unsafe were bad sight, liability to petit-mal or epileptic fits, in some cases the loss of a limb, convalescence from certain illnesses, and progressive paralysis. The question of youth or age i relation to competence could only be decided in ch individual case. His opinion of the woman ver was that “when she was good she was very ry good, but when she was ——” unspeakable. On the whole, he thought women failed through expecting old-world courtesy in tight corners; courtesy was very difficult to extend when three cars were mixed up at a cross-roads. Nevertheless, they were improving every year. To illustrate his ideal of the fit driver he quoted Kipling's lines, beginning: “An even heart that seldom slows its beat, the cool head willing what that heart desires; the measuring eye that guides the hands and feet, the soul unbroken when the body tires.”

The Team Spirit in Traffic.

Mr. MERVYN O'GORMAN said there was not one traffic problem but a cohort of problems which required a scientific approach. All that could be proposed to-day was a method of study, not a solution; anyone who pretended to have a solution was a public peril. Road safety demanded the continuous attention of traffic units to the job of being a traffic unit in traffic; anything that disafter[illegible]d drivers or walkers added to the risk of general [illegible]: bad name-plating, bad lighting, slippery going to and vague signals, for example. When the schools set demand approximated to a man's maximum education the danger line was reached; anything that that up [illegible]ving more difficult or fatiguing or called for simultaneous observation of more objects, or a wider angle of vision or quicker apprehension, could only be tolerated in so far as it added to the intensity of attention. The psychology and physique of the individual, therefore, was a factor. A far-reaching and compulsive rule was: “Show your intention and heed the other fellow's.” No class of traffic unit could be privileged and yet be safe. Transport was required for wealth, life, happiness, and civilisation, and safe speed was essential for transport. The power to accelerate was a power for safety. The exercise of consideration by all to assist the free movement of all would give swifter movement to all. The team spirit was a cardinal necessity.

Dr. P. B. SPURGIN agreed with Mr. Turner's demand for a periodical test of physical fitness. He would apply it first to all drivers of commercial vehicles and of motors plying for hire, as most owner-drivers were medically examined from time to time for other reasons. To Mr. Turner's list of disqualifications he added heart disease; it was not uncommon to hear of elderly men, quite unfit, who had fallen dead at the wheel while driving passengers. Some form of insurance should be made compulsory to compensate both the motorist and the person injured, both by way of personal assistance and of defraying the cost of treatment in hospitals, which at present suffered much loss from treating motor casualties without payment.

Alcohol and the Motorist.

As a police-surgeon Dr. Spurgin saw a large number of motorists accused of being drunk in charge of a car; it was then his duty to say definitely, not whether the accused was fit to be in charge of a car, but whether he was drunk. He would, he said, be very grateful to anyone who could tell him what drunkenness was. The Lord Chief Justice had made the very definite statement that “drunk is drunk,” meaning that there were no degrees of drunkenness, a maxim which was right in law and in common sense. There were, however, degrees of alcoholism, which was quite a different matter. A high authority had expressed the view that that person was drunk who had taken drink to such an extent as to disturb his mental balance and render him unfit to deal with the ordinary matters of daily life. This did not go quite far enough, and the best definition up to date had been that of the British Medical Association: that a man was drunk who at the material time was so affected by the influence of alcohol that he was unable to perform his ordinary functions normally. The ordinary function of the motorist was driving the car, and if he was overcome to any extent by alcohol he was unfit to drive a motor-car and therefore drunk. Like the seven ages of man, there were seven stages of drunkenness, and it was a moot point at which of them drunkenness itself began. The stages were: relaxation, bonhomie, expansiveness and loquacity (somewhat dangerous ground); cantankerousness (here there was little trouble in diagnosis), pugnacity, somnolence, and coma. The layman did not understand the difficulty of the problem presented by these border-line motor cases. Clever barristers sometimes pulled medical evidence to pieces in detail when the witness had based his opinion on the accused's condition as a whole, and their clients got off. Nevertheless, many suspects were released from custody at once because the police-surgeon could not quite certify them drunk, and those who escaped when actually charged were very lucky.

Some Practical Suggestions.

Mr. MASSAC BUIST reminded the meeting that the problem was to reduce, not necessarily the absolute number of accidents, but the number per mile per head. The work was badly hindered by the lack of statistics. The law of motoring would, he hoped, be made clear and up to date, but its administration was another matter altogether; while there were still magistrates who spent their time hounding the police on to prosecute for every minor infraction, statistics based partly on police-court results would be deceptive. Public education was necessary in many directions. A factor which produced a large number of accidents was the general tendency to drive old cars, with their high centre of gravity and indifferent brakes, like new ones. It was also an astounding fact that many persons who had driven for months could not reverse their cars; the "fair-weather" driver was a great danger. Moreover, the percentage of drivers who could control a skid had never been so low. Many drivers needed education in the art of signalling without forgetting their own intentions and obstructing the traffic. It had been said that many roads were so steeply cambered that it was impossible to drive on the left; this was largely a matter of training, though manufacturers would have to pay more attention to the solidity of their wheels.

He recommended the American plan of making all drivers, at certain cross-roads, actually stop their cars before proceeding; this was a marvellous preventive of accidents. The weakness of a driving test was that it did not necessarily expose the candidate's ability to deal with an emergency. The insurance companies opposed compulsory insurance because they thought it would force them to take risks they would not otherwise accept, but Mr. Buist proposed that insurance against third party risks should be compulsory for drivers and optional for companies. This would make the companies the means of ridding the roads of the really bad drivers and—a less recognised danger—the bad example they set to beginners. The great difficulty in the way of financial assistance to hospitals for the treatment of motor casualties was that neither the press nor the public would take any interest in the movement. Insurance companies were at present unable to pay over to the hospitals any part of the sums awarded to their clients, and legislation was needed if this me[illegible] tracti collision [illegible] to be available. A very heavy fine patches [illegible]ted on persons who absconded without sum of the capacity t[illegible] inducing local practitioners to treat do dr[illegible]

Discussion.

Lord RIDDELL advocated that doctors and hospitals who had treated motor casualties should have a right of action for fees with a first charge on the patient's vehicle.

Mr. BERNARD O'CONNOR suggested that all motorists should be trained and examined on the same plan as that applied by the London General Omnibus Company. In a collision with a pedestrian, when the court found contributory negligence on both sides, the motorist fared worse because he caused the injury.

Dr. CAMPBELL McCLURE proposed and Sir BRUCE BRUCE-PORTER seconded a vote of thanks to the speakers.

Lord HOWE, replying, pleaded for the spirit of sportsmanship, which would go a long way towards solving traffic problems.

MANCHESTER MEDICAL SOCIETY.

AT a meeting held at the University on Nov. 6th Prof. E. D. TELFORD described two cases of

Hydatid Disease of the Lung.

The first case was that of a boy, aged 14 from whom a large cyst of the lung was easily removed by thoracotomy. In the second case, a woman of 40 had made a complete recovery after the spontaneous expectoration of two very large hydatid cysts of the lung. Dr. Telford emphasised the frequency of multiple cysts in the same patient and produced evidence to show that the hydatid cyst was of much slower growth than was commonly supposed. Diagnosis was based on the occurrence of eosinophilia and anaphylactic phenomena with the aid of the complement-fixation and Casoni tests. Small hydatids deeply placed in the lung might, he thought, be left to expectant treatment, but hydatids near the pleural surface should be submitted to operation owing to the risk of rupture into the pleural cavity.

Dr. FERGUS R. FERGUSON read a paper on the

Familial Ataxias.

The term, he said, was originally employed to denote a number of cases of ataxia with an hereditary or familial incidence, but as the years have gone by it has come to be used to include a variety of different diseases, many of which show little or no ataxia. The tendency has been to regard these diseases as more or less distinct and separate entities, although for the sake of convenience they are generally included in a neurological text-book under the same heading. The group includes the ataxias associated with the names of Friedreich, Marie, Sanger Brown, and Neff, families described by Klippel-Durante, Cestan and Guillain, Ballet and Rose, Batten, Miura, so-called familial disseminated sclerosis and familial spastic paralysis. The cases described by Sanger Brown and Neff seemed to be confined to the original family, but Gordon Holmes had clearly shown that there were numbers of cases masquerading under the name of Marie which were quite unlike his original "hereditary cerebellar ataxia." The clinical picture, in fact, varied according to which system—psychological, cranial nerves, pyramidal, extrapyramidal, sensory, and cerebellar—was affected. The probable unity of these various diseases was suggested by the occurrence of Friedreich's and Marie's form in the same family (Bayer and Gy, Ferrier and Chassin), by transition types between the two (Perrero, Lenoble, and Margulies), and by the evidence of a family, investigated by Dr. Macdonald Critchley and himself, in which 13 members were affected, most of them with the following features: (1) age of onset, 35–45; (2) euphoria and emotional instability; (3) ocular paralyses, nystagmus, and optic atrophy; (4) evidence of pyramidal disease; (5) widespread sensory disturbances; (6) certain extrapyramidal manifestations. Superficially, some of these cases resembled and had been diagnosed as Parkinson's disease or disseminated sclerosis. Although post-mortem evidence was lacking, probably all had a common pathological basis in hereditary abiotrophy of the neurones.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

CLINICAL CASES.

A MEETING of this Society was held at the Aberdeen Royal Hospital for Sick Children on Nov. 7th, Prof. A. LOW, the President, being in the chair, when a demonstration of clinical cases was given by members of the staff.

A Case of Spinal Curvature.

Mr. A. MITCHELL showed a boy of 7 with a year's history of pain in the back and loss of weight. On examination there was scoliosis of the dorsal region of the spine with curvature to the right and slight kyphosis. The last dorsal and first three lumbar vertebræ were prominent. There was pain in the lumbar region on jarring the spine. The boy walked unwillingly, with a crouching gait, supporting himself by holding his thighs. There were no signs of pressure on the spinal cord or nerve roots. The Wassermann reaction was negative. X ray examination showed the presence of lesions involving three pairs of vertebræ, ninth and tenth thoracic, twelfth thoracic and first lumbar, and third and fourth lumbar. Mr. Mitchell did not think that the lesions were tuberculous, in view of their multiple nature, but suggested the possibility of a multiple septic infection.

THE TREE AND THE FRUIT.

THE British Science Guild was founded in 1905 by NORMAN LOCKYER, the famous physicist and astronomer, who died some 15 years later. The object of the founder was to promote by organised effort the application of scientific methods and their practical issues to public affairs generally, thus instructing the country that it must look to science, as it advances, for the main solutions of fundamental social problems. In an appeal directed to the public last week by Lord MELCHETT (the president of the Guild), Sir RICHARD GREGORY and Dr. J. S. YOUNG (respectively chairman of the executive and finance committees of the Guild), and Lady LOCKYER, assistant treasurer, it is indicated that the advancement of science for public good lies especially within three spheres of endeavour—namely, that of research, that of education, and that of propaganda in advocacy of the benefits to be obtained through science alike by Government departments, educational and local authorities, and individual employers. This last sphere of work for public good the Guild claims to have filled successfully by the aid of experts in science in all its branches, whose aid has been given gratuitously, a fact which enforces the appeal of the Guild for financial support.

Under the foundation of the Guild lectures are given each year associated with the name of NORMAN LOCKYER, and last Tuesday the fifth of these lectures was delivered in the Hall of the Goldsmiths' Company by Sir WALTER FLETCHER, secretary of the Medical Research Council, who asked a large audience to consider broadly the field of work which is tilled by the followers of medicine. With such a scope for an address the lecturer could only attempt to dwell upon certain features or episodes that have significance for our guidance at the present time, and in the historical drama of the evolution of medicine he selected the changes during the three centuries between the accession of HENRY VIII. and QUEEN VICTORIA as illustrative of the whole story. In an interesting comparison of the development of the mathematical, chemical, and physical sciences with that of medical science, he pointed to the fact that in the former there had been a progress that had been [illegible]ontinuous in the main from the days of Greek civilisa[illegible] onwards, while in the latter there have occurred [illegible]ificant breaks in the forward march. Clearly [illegible]ing the Dark Ages there was no regular development in our knowledge of physics, but, despite the huge material obstacles, the study of both mathematics and chemistry was maintained. In the case of medicine, however, the scientific status remained unaltered, save in a few sporadic directions, between the first century B.C. and the seventeenth century. Here and there discoveries that proved of value were made sporadically, but for the most part the superstitions of old mythology befogged the path of medical learning, prevented the doctor from searching out the truth on the lines of natural philosophy, and even prevented him from following the teachings of HIPPOCRATES, whose doctrines throughout this long period represented the truth. These doctrines lost by the inventions of many disciples and gained little from any additions to knowledge of natural philosophy. This is a curious reflection when we remember the debt that modern developments of professional equipment owe to our increased familiarity with physics and chemistry and their mathematical and physical foundations. Why did not the acquisition of physics, which proved so fruitful of result in the material and moral development of the world, have no correlating influence upon medicine and surgery? To this question there is no single answer, but two circumstances are predominant as contributing to the explanation, if not explaining the anomaly. First the material with which medicine and surgery have to deal cannot be treated in the main on mathematical or logical grounds; and secondly, when the rule and the balance can be trusted, the microscope is very generally an adjuvant for the obtaining of necessary information, and the microscope did not arrive until after the death of HARVEY.

And now, in compensation for the lagging of the past, we have so fierce a rate set to medical progress that neither our educational machinery nor our laboratory methods can keep pace. Not only, as Sir WALTER FLETCHER pointed out, has medical knowledge come so tumultuously as to allow no proper time for the adjustment of the traditional system of medical training, but the new learning is often so directly associated with researches in the domains of physics and chemistry, which can only be conducted by experts along their own lines, that the initiative often passes from the physician to the scientific worker in the laboratory. These words must not be taken to imply a supersession of medicine, for their significance is exactly in opposition to this; we have, on the contrary, a practical proof here of the growth and development of medicine, in that the art and science of healing are steadily annexing the results obtained by workers engaged in other provinces of wisdom. But as these provinces, as well as the province of medicine thus allied to them, are alike in the stage of a rapid acquisition of knowledge, it can be readily believed that scientific workers are sorely needed. What is not so easy to believe, though equally true, is the fact that these workers, even the leaders among them, are not duly rewarded by the public. Though the happiness of the world's future may depend upon the activities of the army which is wresting from Nature her secrets, that army is undermanned and ill-paid.

◆

CANCER OF THE STOMACH.

SOME 16,000 persons die annually in Great Britain from cancer of the stomach. So rare is it for a case of this disease to be cured, or even to give the semblance of cure for an appreciable period after treatment, that many clinicians state freely that they have never seen such an occurrence, and surgeons are glad to exhibit at medical societies any rare cases in which they have been able to prolong life for more than a few years. At a time when the whole world is more than ever interested in cancer research, and when the activities of the Radium Commission are raising hopes which have never been entertained before, it is perhaps salutary, if discouraging, to reflect that at the present day there exists even with the latest radiological technique no real avenue of hope for the sufferers from this, the commonest of all forms of cancer. Established cancer of the stomach is not difficult to diagnose—tumour formation, vomiting, and cachexia are signs which are unmistakable and are usually harbingers of impending doom; but apart from these late features, there exist to-day diagnostic facilities which enable this disease to be recognised by the expert physician after quite a brief observation of the patient whose dyspepsia or other early signs have led him to seek advice. In the course of the discussion at the Medical Society of London on Nov. 11th, which we reported last week, it was made clear that even when clinical examination yields no clue, the competent radiologist can detect loss of motility in the gastric wall, early malignant ulceration, or a minute filling defect in the very early stages of cancer of the stomach. Moreover, the expert in gastric analysis is able to find changes from the normal picture of gastric secretion yielded after a test-meal, which confirm the suspicions of the physician.

Even when cancer of the stomach is diagnosed practically as soon as the patient seeks medical relief, there is little hope of cure. The clinician of the future will either have to discover entirely new methods of treatment, or, if reliance is to be placed upon existing methods, to diagnose the disease before ever it gives rise to symptoms. In the face of this problem any authoritative comments on the precursors of carcinoma of the stomach are clearly of interest. Dr. A. F. Hurst thus chose a valuable subject for his Schorstein Lecture, which appeared in our columns last week. Starting with his expression of belief that cancer never invades a healthy stomach, he proceeded to discuss the conditions which he believes to be its precursors. The old idea that free hydrochloric acid was absent in practically all cases of cancer of the stomach has been banished since the introduction of fractional gastric analysis, and most experienced observers now agree that this acid is to be found in about half the cases examined if it is carefully sought for. It still remains a remarkable fact that a considerable proportion of cases of cancer of the stomach exhibit achlorhydria, and Dr. Hurst believes that this condition is not the result of malignant change but is an expression of chronic gastritis which has been present in the patient perhaps for many years, and has been the predisposing cause in the development of the carcinoma. His personal experience goes to show that achlorhydria does not develop in the course of the disease, and that among cases of cancer of the stomach in which the history of dyspepsia is short the majority can be shown to exhibit this phenomenon. It is now generally recognised that one of the most important functions of the gastric secretion is to sterilise, at any rate partially, all material which enters the stomach. When, therefore, the secretion of acid is defective, not only is the softening and dilution of the foodstuffs impaired, but any pathogenic organisms swallowed have ample opportunity to increase the irritation thus mechanically produced. In this way progressive damage to the secreting tubules and mucous membrane develops, and in time an achlorhydria, which at first may have been due to temporary blockage of the secreting glands, becomes permanent owing to the destruction of these tissues. Earlier recognition of achlorhydria and gastritis might be expected if patients could be persuaded to submit themselves to routine examination during various periods of their lives, and in this way treatment might be more frequently instituted at an early stage. Dr. Hurst believes that the other group of cases which show a very definite concentration of hydrochloric acid are for the most part those of malignant change occurring in a chronic gastric ulcer. These cases form the majority of those in whom the history extends back for more than a year, and he believes that in this group must be placed about 20 per cent. of all cases of cancer of the stomach. With this conclusion many physicians will find it difficult to agree. It is true that a number of surgeons of great experience, including such authorities as Lord Moynihan and the surgeons of the Mayo Clinic, have taught that malignant change is by no means uncommon in chronic gastric ulcers. Their opinion has been founded largely upon the histological reports on material removed at operations. The figures of L. B. Wilson and W. C. MacCarty from the Mayo Clinic purported to show that the vast majority of cases of cancer of the stomach gave histological evidence of previous simple ulcers, and that 68 per cent. of apparently simple peptic ulcers, when resected, showed evidence of malignant change. These figures have been much disputed both in this country and in the United States. The evidence is subjected to close analysis in the important book on "Gastric and Duodenal Ulcer" recently published by Dr. A. F. Hurst and Prof. M. J. Stewart,[1] where the latter carefully surveys the results of work on material received in the pathological department of the University of Leeds in recent years. Prof. Stewart's series included 259 specimens removed at operation; 70 of these were frank cases of carcinoma, 11 of which were held to yield strong evidence that a simple ulcer had preceded them. Of the remainder, 11 showed early malignant change in the margin of an apparently simple gastric ulcer. Prof. Stewart believes these figures to be on the conservative side, in that a short history in some of the cass of obvious cancer did not, in his opinion, exclude the possibility of a rapid malignant change in an ulcer which was originally simple. This evidence has clearly been responsible to some extent for Dr. Hurst's belief that a chronic ulcer is the precursor of malignant disease in 20 per cent. of all cases of cancer of the stomach.

The reasons why many will disagree with him must, however, be stated with equal prominence. In the first place, the opinion of a pathologist, however eminent and careful, as to whether a lesion in any given specimen of malignant disease examined has been present for years as a benign ulcer is at best an opinion which would not be easy to prove conclusively. In the second place, it is impossible to escape from the remarkable fact that practitioners and physicians who have cases of chronic gastric ulcer under their care, sometimes for many years, do not see these cases gradually transformed into examples of cancer of the stomach. Dr. Hurst in his Schorstein Lecture records only one case in which he believes he has seen the development of malignant change from a simple peptic ulcer, and the critical reader will note that even in that case the symptoms had been present for a relatively short period. Records of cases of long-standing peptic ulcer terminating after years in malignant disease are exceedingly rare. In our view gastric ulcer has not yet been proved to be an important precursor of cancer of the stomach. But while it would be too optimistic to assume that the successful treatment of gastric ulcers throughout the country would have an important effect on diminishing the incidence of malignant disease of the stomach, there is nowadays no excuse for leaving an unhealed ulcer untreated, especially since medical treatment is proving such an effective weapon. Dr. Hurst himself admits that there is very little danger of malignant degeneration of a healed scar, and points out that in Prof. Stewart's series of specially studied operation cases there was only one example of cicatrix cancer compared with 11 of ulcer cancer. It is possible that the ætiological connexion between gastric ulcer and gastric cancer will remain for ever unsolved, since the general recognition and prompt treatment of the former lesion by modern medical or surgical means will make a chronic ulcer of long standing a clinical rarity.

Annotations.

"Ne quid nimis."

THE OPTICAL PROPERTIES OF THE CEREBRO-SPINAL FLUID.

DURING the last 20 years the cerebro-spinal fluid has provided a rich field for those who have the desire and ability to search for the hidden things in the chemistry and physics of the body. The chief value of this fluid from the point of view of research lies in the constancy of its normal chemical and physical composition, and in its comparative freedom from the proteins and protein compounds which complicate the physico-chemical examination of the blood. Since Mestrezat settled the normal chemical composition of the fluid many investigators have examined the relation of variations in this to variations in blood chemistry with fruitful results. It may even be said that the chemistry of the cerebro-spinal fluid in disease has in many ways helped us to understand the chemistry of the blood. More recently the finer methods of the physical laboratory have been applied to the cerebro-spinal fluid, partly from a pure desire for knowledge, and partly in an attempt to find new methods which will help in the diagnosis of disease. Electric properties, such as electro-conductivity and the electric charge of the proteins, have already been examined, and now the optical properties of the fluid are being investigated by modern instruments.

Two recent papers deal with the refractility of the fluid and its power of absorption of the ultra-violet end of the spectrum. Penfold and Price,[1] who have investigated the refractile properties of the fluid with the Zeiss dipping refractometer, had the results of several previous workers as a basis for their investigations. It may be said at once that their results agree closely with what had previously been found. They establish the normal refractility at 1·33510 in the adult and 1·33508 in the child, with variations of no more than six units in the fifth decimal place. Any greater variation they have found to be pathological, and to indicate some disturbance either in the chemistry of the cerebro-spinal fluid alone or more commonly in the chemistry of the blood. The chief value of their work appears to lie in the correlation which they have sought and sometimes obtained between the changes in the proportions of the chemical constituents of the cerebro-spinal fluid and the alterations in refraction. Thus in nephritis and diabetes the refractility as calculated from the chemical examination might be identical with that obtained directly by the refractometer. When this parallelism was not obtained it was considered that some chemical substance which had not been investigated in the routine examination was present in abnormal concentration, and a further examination might reveal this. In diseases of the central nervous system there was often little departure from the normal refractility, since an increase in protein might be compensated by a reduction in the chlorides or glucose. Increase of refractility was much more common than reduction, and was the rule in many diseases of the nervous system, such as cerebral and spinal tumour. On the whole, however, the refractometry of the cerebro-spinal fluid appeared to be of more clinical value in general diseases such as uræmia and diabetes than in diseases confined to the central nervous system.

The absorption of the ultra-violet end of the copper arc spectrum has been studied by Fretson Skinner,[2] who hoped to gain by this means some indication of the nature of the colloids present in the cerebro-spinal fluid. In this he was disappointed, for the absorption of ultra-violet rays appeared to have no necessary relation to the colloids in the fluid. Nor were any characteristic bands observed. He did, however, find important variations from the normal in certain diseases. Thus tabes dorsalis constantly caused an increased absorption at the ultra-violet end of the spectrum, general paralysis rather more, and tuberculous meningitis much more. Some diseases, such as disseminated sclerosis, might, however, give almost normal spectra. The number of fluids examined and the exact spectrum given by each is not stated. This method of examining the cerebro-spinal fluid is of some theoretical interest, but until the results which it gives can be correlated with changes in the constituents of the fluid it is likely to be of little practical value.

SNAKE-BITE AND ANTIVENIN.

SNAKE-BITE does occasionally, if rarely, give rise to alarming symptoms in this country, as our correspondence columns recently testified.[1] Our only poisonous snake is the adder, but in the United States of America rattlesnakes are responsible for the majority of cases, although the number of bites by copper-heads exceeds those of any other one species. In the current *Bulletin* of the Antivenin Institute of America, R. H. Hutchison has collected 607 case reports of snake-bite for the year 1928, and found that the species of snake could be identified with a fair degree of accuracy in three-quarters of them. From April until July the risk of snake-bite increases steadily, but it begins to decline again in the middle of September, and has practically ceased to exist by the middle of October. The greatest danger seems to lie in picking up or reaching for something on the ground, because any movement towards an unseen snake will elicit a lightning-like defensive bite. The symptoms vary considerably, but in most cases swelling and pain appeared early, and were the outstanding features. If the bitten part did not hurt and swell, the snake was either non-poisonous or its injection apparatus was not working properly. Other symptoms noticed were weakness, giddiness, hæmorrhage, difficulty in breathing, nausea and vomiting, as well as a host of occasional disturbances. The reports include almost every conceivable method of treatment, from the application of a freshly killed chicken to cauterisation, and specific treatment with antivenin. From this abundance of recommendations three first-aid methods have emerged as having real value. The first is the application of a tourniquet above the bite, drawn tightly enough to obstruct venous return. It should be released every quarter of an hour for at least two minutes to re-establish the circulation, its purpose being only to diminish the rate at which the venom enters the general circulation. The second measure is a crucial incision over the bite, deep enough to allow the escape of serum, and the third is mechanical suction to withdraw free venom. Experiments on dogs have shown that the common applications, such as potassium permanganate, kerosene or turpentine, are useless. Potassium permanganate oxidises and destroys the venom outside the body, but in the poisoned wound its local destructive action does more harm than can be balanced by the possible destruction of some unabsorbed venom. A review on the fatal cases emphasises the importance of early treatment under competent medical direction. In half the cases which eventually died there was delay of more than two hours before the first dose of antivenin was given. Antivenin gives prompt relief, and as long as the patient is alive there is a chance that it will counteract the poison. The Institute recommends as first-aid measures, the application of a tourniquet a few inches above the bite and an immediate subcutaneous injection of antivenin, supplemented by incision and suction if the bite has been inflicted by a large snake and if the symptoms are severe and develop rapidly. The victim is advised not to run or get hot, and to avoid alcohol and cauterisation. The antivenin injection should be repeated every half hour unless and until symptoms are markedly reduced, and intramuscular injection is better than subcutaneous; while for cases not seen until some time after the bite intravenous or, for small children, intraperitoneal injection is recommended. Caffeine, strychnine, and intravenous saline should be available where there is much shock.

[1] THE LANCET, Oct. 5th, p. 744; and Oct. 19th, p. 850.

The Walter and Eliza Hall Institute of Research in Melbourne is devoting a special grant from the Commonwealth department of health to researches on the Australian snake venoms. Venom is being collected from a large number of snakes by making them bite through a fine piece of rubber stretched across a medicine glass. The death-rates from the common snakes in Australia are 50 per cent. from the death-adder, 40 per cent. from the tiger snake, and 9 per cent. from the brown snake. Dr. K. D. Fairley has studied the results of intravenous injections of venom in sheep, and has found that the clotting-time of the blood is increased but that no intravascular clotting was caused. He has also studied the dentition and bite mechanism of the venomous snakes, and places the death-adder first and the brown snake last. In another paper he shows that a snake which has recently struck may still be dangerous, for even after biting several times it may still have an appreciable amount of venom left in the gland. His experiments suggest that tiger-snake venom, after the natural bite, is absorbed into the circulation in less than two minutes, so that if ligature and incision are to be effective they must be applied within this time. The value of this method depends on a thermolabile constituent of the venom, for if the thrombase in the venom was destroyed by heating to 75° C., ligature only delayed and did not prevent death. On the whole, therefore, he does not think that ligature is of very much use except to delay absorption, while the excision is being carried out. Dr. C. H. Kellaway, director of the Institute, has described a new phenomenon in the action of the snake venoms on isolated smooth muscle. The reaction closely resembles the anaphylactic reaction; the muscles can easily be desensitised, and one venom will sensitise to others. The action of the venom appears to be on the muscle itself, and not on the end plate, and the desensitisation is permanent.

IRRADIATED MILK.

STANDARDISATION in the vitamin content of foods has made an important step forward. On p. 1090 of our present issue Miss K. H. Coward, D.Sc., makes a comparison between irradiated cow's milk, and cod-liver oil as sources of vitamin D, and she is able to do this accurately by comparing both with a standard solution of irradiated ergosterol. She takes as her standard the antirachitic power of one ten-thousandth of a milligramme (0·0001 mg.) of irradiated ergosterol and calls this one antirachitic unit. Though this unit is not as yet universally adopted, its use is certainly an important step in the right direction. Dr. Coward was able to demonstrate that the antirachitic value of the milk was very materially augmented by a brief period of irradiation—30 seconds approximately. Before irradiation the milk only possessed about one twenty-fifth of an antirachitic unit per gramme; after irradiation the value was enhanced to one-fifth of a unit, and in some cases, differently irradiated, to two units per gramme. Thus a child receiving a litre of milk daily would get the equivalent of 0·004 mg. of irradiated ergosterol in the non-irradiated milk, while in the best irradiated milk the equivalent would be 0·2 mg. The former amount would probably be insignificant, but the latter might be adequate prophylactically, though probably not curatively for an infant. The usual curative dose for an infant is from 1 to 2 mg. Dr. Coward lays emphasis on the marked deficiency in antirachitic potency of ordinary milk which has not been irradiated. On Oct. 5th we published a paper by Dr. Chalmers Watson and others in which some remarkably successful cures of rickets with irradiated milk were recorded. The amount of milk given was not very large, and for some reason it seems to have been effective in one case in which the specific antirachitic agent, irradiated ergosterol, is stated to have failed. On the other hand, H. Hentschel and A. Roszkowski[1] express themselves strongly against the use of irradiated milk in the treatment of florid rickets, as compared with the use of irradiated ergosterol. If it could be ensured that irradiated milk, at no enhanced cost, would reach children who are not touched by any other form of antirachitic prophylaxis, it might have a considerable value; but otherwise it seems undesirable that its use should replace that of irradiated ergosterol, which is specific in the treatment of rickets.

PATHOGENESIS OF CONGENITAL SYPHILIS.

THE poverty of the material at the disposal of the clinician and more especially the clinical teacher of to-day, as compared with that to which he had access at the beginning of the century, has been remarked upon by physicians when occasion has led them to retrospect of their own experience. Sir Humphry Rolleston, in a remarkable address to the Medical Society of London on changes in the clinical aspects of disease, drew attention to the increased rarity of certain morbid conditions, due in some cases to the effects of treatment and in others to variations in the virulence of infective agents. Dr. F. J. Poynton, in his presidential address to a section of the Royal Society of Medicine in the present year, reminded his hearers of the kind of material that presented itself to pediatrists of the time of Cheadle—material which at any rate in civilised countries will never be seen again. Since it may well be said that the greatest advances in preventive and curative medicine have been made in connexion with diseases of the young, it is likely that in these disorders especially the material furnished by the past was superior to that of to-day. This fact does not apply to the clinician alone, but exerts a considerable effect on the activities of the pathologist, almost always with the result that he is driven to employ more indirect methods of investigation, and that the exact stages and sequences of the morbid process are more difficult to determine. No more striking testimony to the existence of this state of affairs could be forthcoming than the recent appearance[2] of Dr. Oluf Thomsen's pathological atlas of congenital syphilis in the fœtus, a disorder which has to so great an extent been modified by antenatal supervision and specific treatment. Dr. Thomsen has reproduced in a separate volume (with a short explanatory text written in German) the illustrations taken from his comprehensive work on the subject published in Danish in 1912. He justifies this course by the statement, which no one who has seen the material will be likely to challenge, that it would hardly be possible to obtain a collection of specimens at the present date which would be in any way its equal. He has incorporated with these illustrations a review of the problems connected with the transmission of syphilis to the fœtus, and discusses the evidence which has accumulated in the years since they first appeared, giving a lucid summary of his interpretation of this evidence. In general, he has found little cause to alter the view which he formerly expressed, that the infection of the fœtus is a placental one, and that a germinal (paternal) one is a hypothesis unsupported by evidence. Dr. Thomsen puts forward as facts of great significance that it has never been shown that an ovum infected with the spirochæte is viable (*lebensfähig*), and that in all the material which he investigated he has failed to find definite histological evidence of syphilis in a fœtus less than 5 months old.

[2] Pathologisch-anatomische Veränderungen über die Congenitale Syphilis bei dem Fœtus und dem neugeborenen Kind. Copenhagen: Levin and Munksgaard; Leipzig: Georg Thieme.

He believes that this is to be explained by the fact that infection invariably takes place through the placenta, and that the latter does not become permeable to the virus until some period in the middle of pregnancy. The appearance of these admirable illustrations in a more accessible form will render available to a much larger number of readers some very important work on these questions.

ANNUAL HOLIDAYS.

A PRIVATE Members' Bill, introduced last week, proposes to grant to every employed person, after 12 months' work, a holiday of eight clear consecutive days with pay. The parliamentary debate on this Bill, which is reported in another column, makes interesting reading. No speaker objected to the principle embodied in the measure; but the opponents advanced arguments based on the claim that the cost would be prohibitive, without in any way considering the value of the increased efficiency arising from a well-earned rest. Few who have studied the results of establishing for human beings those hours and conditions of work which make for health, have any doubt that industry, efficiency, and even wealth result from their adoption. Instance after instance was quoted of trades in which this scheme is already honoured; each is to-day a successful trade. Yet the others close their minds to the idea that in this and in similar schemes for welfare lie the secret of success. The fact quoted in the debate that probably 40 per cent. of the workers in Europe to-day are under agreement of some sort to be paid while they are having their holidays will come to many as something of a revelation of the social advances being made among our immediate industrial rivals. Industrial economics always allow substantially for the replacement of machinery, and similarly should allow also for the resuscitation of the human element as a paying proposition. All Government employees, either established or unestablished, who come under the class of industrial workers now receive an annual holiday with pay. Clearly the time is due when this commendable example should be extended to the whole nation by Act, as are bank holidays. What is right and advantageous for the health and efficiency of our successful industries cannot but be good for the nation as a whole. The Bill was accorded a second reading, but no hope was held out that time will be granted for its passage through the House.

INTERNATIONAL HEALTH IN 1928.

FOR the fourth successive year the League of Nations has published an International Health Year Book, which offers valuable statistics for the comparison of sanitary organisation in 29 countries and under 35 Public Health Administrations. A large amount of thorough and important work is embodied in the volume for 1928[1] and an effort has been made to reduce the tables given for different countries to a corresponding scheme; unfortunately, in some cases suitable figures were not available so that direct comparison between all nations represented proved impossible. The probable inclusion of Egypt in the League of Nations in the near future makes the consideration of the statistics given for this country of some political interest. Great strides have been made of late years in the organisation of the Egyptian Public Health Department, and in 1927 the whole system was coördinated by the creation of a Ministry of Public Health. It is, of course, inevitable that Egypt still lags some way behind European countries, for two reasons: in the first place public health work in that country has been of comparatively short duration—the Public Health Department was formed only in 1886—and in the second place the rising population and the limitation of territory by the fertility of the Nile Valley makes overcrowding a serious and increasing problem. Public health work in every direction meets with this problem, especially, needless to say, in the large cities. To take an example a street sweeper in Cairo may be paid only five piastres a day (one shilling), out of which he supports himself and often two wives and families. Thus a nursing (and possibly pregnant) mother with three or four young children will feed herself and them for about two piastres a day on a diet of dates, beans, and vegetable rissoles, obtained from a street-vendor whose wares are spread on the ground at the corner of a dusty street, and voraciously haunted by flies. It is not surprising, then, that the death-rate among young children remains high as compared with the rates in European countries, and that it is tending to rise. The mortality among Egyptian infants under one year of age is given as 146 per 1000 live births during 1926; in Germany for the same year it was 102, in France 77, in Denmark 85, in England and Wales 70, and in the Irish Free State 74. The conditions giving rise to this marked difference are not such as can be corrected effectively or completely by sanitary legislation, as they are partly industrial and largely due to overcrowding. Various other factors will obviously contribute to the same end; superstition and ignorance play a large part, but these will naturally have less effect as education improves. The high infant mortality is more than balanced by the high birth-rate, which has always been on the increase in Egypt except during the war years. The birth-rate per 1000 inhabitants, however, shows a slight drop in the statistics for the last two years given—13·2 in 1926 to 42·7 in 1927. Yet this figure is extremely high when compared with the following: Austria, 17·8 per 1000 inhabitants in 1927, France 19, Germany 18·4, and England and Wales 16·6 in the same year. With a rising population in a limited territory, a high mortality among infants becomes almost a necessary condition of life to the survivors. It will be interesting to see what means will be used by the Egyptian Ministry of Public Health to attack this problem; a partial and temporary relief may, of course, result from improvements in damming and irrigation. The statistics supplied by the League of Nations should be of especial value to the administrators of countries such as Egypt whose conditions of public health are below the average of all the nations. The summaries provided of measures obtaining elsewhere may not be detailed enough to show how they could be adapted to local conditions, but may at least stimulate inquiry and eventually their study may lead to a general increase in efficient public health service throughout the civilised world.

THE DOCTOR AND THE MOTORIST.

THE urgent problem of how to reduce the increasing number of road accidents concerns the medical profession both as motorists and as doctors. The discussion held last Monday by the Hunterian Society, and attended by the Medico-Legal Society, clarified many important points in this aspect of State medicine. The chief heads of the subject are the desirability of tests of competency and of physical and psychological fitness for drivers; compulsory insurance; the remuneration of voluntary hospitals and private practitioners who treated casualties; drunkenness in drivers; general education; and direct legislation. The speakers all agreed that some test of physical fitness was urgently required and probably some form of psychological test as well, but recognised great difficulty in laying down a uniform syllabus and in administering it when laid down. Earl Howe, better known perhaps by his former title of Viscount Curzon, made the practical suggestion that competency tests should be voluntary and conducted by local panels who would issue graded certificates. The value of these in legislation and insurance would make them a practical necessity; moreover, the possibility of obtaining a higher certificate would provide an essential factor in motoring education which is now lacking—the incentive to improvement. Mr. E. B. Turner and others relied on the physical test to eliminate drivers suffering from defective special senses, essential limbs, dangerous heart disease, progressive paralysis, and similar conditions which constituted a danger in themselves. There was a general consensus of opinion that a test for temperament, quickness of reaction, self-control, and other psychological qualities was as yet hardly worked out and was certainly not capable of general application, but no one doubted its desirability as an ideal. Mr. Mervyn O'Gorman, vice-chairman of the Royal Automobile Club, stated what, if it can be confirmed, is a most interesting observation, that 50 per cent. of all accidents, avoidable and unavoidable alike, happen to the same 20 per cent. of drivers. It would be well worth the trouble and expense to eradicate this destructive minority, but the process might not be popular. Compulsory insurance is repugnant to many insurance companies, but Mr Massac Buist suggested compelling drivers to insure as a condition of their licence, and then leaving the insurance companies to refuse the bad ones. It is obvious that some provision is required to protect third parties against the results of the motorist's default or failure to insure himself. Connected with this is the proposal that insurance companies should pay an adequate sum out of awarded claims to remunerate hospitals which have treated traffic casualties free, but nothing can be done in this direction without legislation. Mr. Buist complained that the public took no interest in the question at all, and if this is so, there is all the more reason for the medical profession to busy themselves with it. The burden of motor casualties presses on some hospitals with a very grievous burden, and there is little sign of a general recognition by these patients of their moral obligations. Complaints are also made by many private practitioners that victims of minor motor accidents often disappear quickly after treatment without paying for it. Lord Riddell's suggestion will appeal to many: that hospitals and practitioners should be given a right of action against these patients, with a first charge on the motor vehicle. Dr. Percy Spurgin deplored the unsatisfactory state of the law on the subject of drunkenness in charge, but hinted that in practice much fewer offenders were charged than ought to be. The chief requirements of general education were the obvious ones of learning to manage the car, slowing at cross-roads, considerateness for other drivers, and the remainder enumerated by Mr. O'Gorman. The discussion showed, therefore, a number of departments of the problem which directly concerned all medical men. The general practitioner can do an enormous amount to solve the traffic problem. He is usually, for one thing, a constant motorist in all weathers, and traffic is familiar ground to him. He sees many motorists as patients and is in a position to warn them when not to drive, and often, by way of hint and fable, to instruct them how to drive, and to draw their attention to the public problems of traffic. Finally, as the person with the greatest moral influence to-day in the country, he can spread Mr. O'Gorman's "spirit of team-work," by practice more than precept.

ETHICS OF DENTAL PRACTICE.

AT the opening of the seventeenth session of the Dental Board of the United Kingdom, the chairman, Sir Francis Dyke Acland, had little of a formal character to report, but struck out a new line by informing the Board of a few of the matters which had arisen in the course of its ordinary business since its last meeting. A number of these dealt with aspects of dental practice interesting from an ethical point of view. A hairdresser had offered to scale his customers' teeth. The chairman felt so convinced that the scaling of teeth came within the words of the Act, "such treatment as is ordinarily given by dentists" (which is prohibited by persons not on the Medical or Dentists' Registers), that he directed the Board to prosecute. Practitioners had inquired whether they might pay the editors of local directories for putting in their qualifications. The chairman advised that it would be in the interest of persons consulting a directory that the qualification in respect of which a practitioner is registered should be inserted free, but that editors might reasonably make a small charge for adding his telephone number. A practitioner had inquired whether he might write to firms offering to set up a clinic for treating their employees. The chairman replied that he found it difficult to distinguish between what was proposed and offering householders to treat their servants or the members of their families, and that, therefore, he had much better not. The Hearts of Oak Benefit Society had made an arrangement with the Public Dental Service Association under which their non-State insured members should be treated at the scale of fees applicable to health insurance patients—the Society issuing to its members a letter containing the words, "It is open to you to present the enclosed letter to your dentist," and a form containing the words, "To the dentist selected by the member." As, in fact, the arrangement only applied if the dentist selected was a member of the Association, the chairman said that the arrangement was unsatisfactory and might easily involve an element of canvassing. The position was being reconsidered. In the last example which he gave, the Board heard that the London Coöperative Society had been asking for a commission from dentists treating their members on the fees which the members had been paying direct to the dentist. The Society had justified this "under the arrangements which they have with dentists and other tradesmen," they expecting a commission "on any trade obtained through their agency." This was, said Sir Francis, an unwise letter on their part, because if dentists obtained patients through an agency there was a suspicion that they were allowing the agent to canvass for them. All the dentists were warned, with the result that the Society became disturbed. It was explained that the letter had been written by a subordinate ("I suppose," said the chairman, "it was only this subordinate who had been responsible for the commission being demanded"), and the Society took the step of informing all the dentists who treat its members that if the patient paid his fees direct, the dentist was not justified in making any allowance to the Society.

RADIUM POISONING TREATED BY A PARATHYROID EXTRACT.

IN the manufacture of luminous paints crystallised zinc sulphide is mixed with radium, mesothorium, or radiothorium. The luminescence of such paints depends on scintillation. It is due to an alpha particle which consists of a helium nucleus containing two positive charges striking the crystalline phosphorescent zinc sulphide and causing a flash. Radium poisoning among New Jersey factory girls who were engaged in painting numerals on illuminated watch dials was first described by H. S. Martland[1] in 1925. It was traced to the habit of pointing camel-hair brushes with the lips. After a latent interval of one to seven years plastic anæmia may develop, and, preceding or following this, severe necrosis of the mandible or maxilla has been reported. "Radiation osteitis" of the femora, spine, and humeri have also been seen in these cases and it was followed by osteosarcoma in 2 cases out of 15. Chemists exposed to the manufacture of the radio-active constituents of luminous paints have met the same fate. C. K. Drinker, in 1925, suggested that the radio-active substances were stored in the bones of the victims, and ultimately, by testing the organs at autopsy by means of the α-electroscope, amounts up to 180 micro-grammes were found in bone, chiefly in the cortex. This discovery supplies the explanation of the bone changes and of the fatal aplasia of the marrow, for 95 per cent. of the rays coming from the bone are alpha rays, which are 10,000 times more destructive of human tissues than gamma rays. The treatment of the condition is, of course, preventive and we have never heard of any cases in Europe where the workers in this trade do not point their brushes with the lips. Removal from exposure, hygiene of the mouth, prevention and treatment of sepsis, and treatment of the anæmia—these, naturally, have all been carried out in cases where symptoms have started. In addition it occurred to several people, including Flinn,[2] to attempt elimination of the dangerous substances from the bone.

---

[1] See THE LANCET, 1928, ii., 612, 625.

As long ago as 1861 Gusserow analysed the tissues of rabbits poisoned by lead and found by far the highest concentration of this metal in the bones. In discussing his observation he suggested an analogy between the storage of lead and calcium in the skeleton and hinted that changes in the organism as a whole might give rise to migration of lead as well as of calcium to and from the bony deposit. J. C. Aub, L. T. Fairhall, and A. S. Minot, in 1924, confirmed these observations experimentally in cats and also in patients poisoned by lead in industry. They found that artificial acidosis produced by large doses of ammonium chloride caused very effective elimination of lead and of calcium. Donald Hunter and Aub, in 1927, used injections of parathormone (Collip's parathyroid extract) and were able still further to increase the output of lead. This principle applied by Flinn and Seidlin to three girls with radium poisoning has caused gain in weight, improvement of the general condition, and great increase of the elimination of radio-active substance in the stools and expired air.

APRIL 1st, 1930.

THE date on which poor-law hospitals and institutions will be transferred to county and borough councils is still four months distant, but if these transferred institutions are to be appropriated by the public health authority on that date there is little time to spare. Memorandum L.G.A.26, which has just been issued by the Minister of Health, asks the councils concerned to submit proposals indicating whether it is their intention when the land in question (including, of course, the buildings upon it) is transferred to them, to apply to the Minister for his approval of its appropriation for the purposes of one of the special Acts. Any application is to be accompanied by a plan showing in a distinctive colour the land and buildings proposed to be appropriated, and by a report from the medical officer of health (or other appropriate officer) describing the present and proposed arrangements of the land and buildings. Couched, as it is, in formal terms, the memorandum deals, nevertheless, with the beginning of a revolution in public health practice. The opportunity was described by Sir Robert Bolam at the annual banquet of the Society of Medical Officers of Health, reported on page 1122, as not merely one of a lifetime, but as an opportunity unparalleled in centuries, for under the new régime the medical officer of health should, he said, be able so to alter the minds of legislators as to make the work of the medical profession at large bear fruit. At the same banquet Sir Arthur Robinson, First Secretary to the Ministry of Health, indicated the many directions in which the Local Government Act of 1929 will affect the public health service. On his right, by a curious chance, was sitting as chairman of the banquet the medical officer of health for Bradford, the only place in the United Kingdom where a general hospital is under municipal control. As a result of the changes which will begin on April 1st next, the exception is likely to become the rule, although, as Sir Arthur said, the right way to set to work is not per saltum, but gradually, quietly, and in the end surely. There may indeed be few councils which will take the drastic step of appropriating on the appointed date the institutions which are transferred to them, but, as the first circular issued by the Minister of Health to local authorities indicated,[1] they are made responsible on that date, severally or jointly, for the provision, maintenance, and management of all public institutions for the cure or mitigation of physical or mental disease. All Fools' Day, 1930, will tax to the utmost the wisdom of the wisest administrator.

CHARLES HOSE.

BY the death of Charles Hose the scientific world has lost a valuable worker in many directions, for although the centre of his activities was always the province of Sarawak the knowledge of natural history which he acquired there and on many expeditions passed into general knowledge through his writings. He entered the services of the second Rajah Brooke at a time when much of Sarawak was unexplored; neither animal nor vegetable, nor indeed human, life was understood, and Hose leapt at the opportunity of research along many and differing lines. He became a mining expert, and his oil discoveries added greatly to the wealth of Sarawak, while his anthropological studies are recorded in the "Pagan Tribes of Borneo," a work written in collaboration with Dr. William McDougall. His personal knowledge of leading tribesmen enabled him to construct maps of hitherto unexplored territory. Hose, who was made an honorary Fellow of Jesus College, Cambridge, in 1926, having previously received the D.Sc. from his University, gave his ethnological collections partly to the University and partly to the museum of the Royal College of Surgeons of England.

THE fifteenth annual report of the General Board of Control for Scotland (H.M. Stationery Office. 2s.) includes, besides details of the present condition of establishments for mental patients, some pertinent general remarks on the provision made for care and treatment of patients in asylums. According to the Scottish commissioners it has long been demonstrated that only a negligible number of the mentally affected cannot be treated under the same conditions as obtain in general hospitals. The desiderata of the ideal mental hospital, therefore, are full facilities for diagnosis and treatment; it should have well-equipped laboratories and a modern X ray apparatus under experienced medical control, and the administration of treatment by means of electricity, water, and light should also be supervised by a doctor. A dental room and a dentist who pays regular visits is highly desirable. The commissioners distinguish Edinburgh District Asylum at Bangour Village by citing it as an ideal hospital as regards provision for diagnosis and treatment, and give high praise to the new solarium being erected at the Govan District Asylum.

EXTENSION OF THE CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL.—Last week Princess Louise, Duchess of Argyll, opened a new wing of this institution. The extension, which has cost £51,000, will greatly relieve the pressure on the waiting-list.

LEICESTER ROYAL INFIRMARY.—On Nov. 13th the the Duchess of Rutland opened the reconstructed West Ward, named after the late Sir Edward Wood Ward, a former chairman of the governors. The day was chosen as being the sixty-seventh anniversary of the day upon which the ward was originally opened, and the same order of service was followed. The cost of the work, including two new operating theatres and their equipment, is £87,000.

LIII.

THE DIAGNOSIS OF ACUTE FOOD POISONING.

PART II.*—LABORATORY INVESTIGATIONS.

Wilful Poisoning.

WITH single cases of suspected food poisoning the possibility of wilful poisoning must be kept in mind. With a wide range of possible poisons it is impossible to discuss either symptoms or post-mortem appearances; these are fully described in books on toxicology. Remains of food left unconsumed by the patient are important to secure as unobtrusively as possible, and in particular any food or drink which may have been consumed only by the sufferer. If vomiting has occurred it is particularly important to secure samples either in bulk or on any linen on which it has been voided. Samples of urine are occasionally useful. In *post-mortem* examinations chief importance attaches to the stomach and this should always be ligatured off carefully with its contents and preserved for examination. Pieces of the small intestine should also be ligatured and preserved as well as the kidneys and liver. Other internal organs are less useful. It is essential to place the organs in jars which can be securely stoppered and *sealed* to prevent the possibility of tampering.

Local Inquiries by the Physician.

We must distinguish between the preliminary inquiries of the physician in charge of the cases and the more detailed and searching investigations possible to the medical officer of health with his facilities as regards right of entry and inquiry, and with the help he can call upon from the staff at his disposal. All outbreaks should be notified to the medical officer of health and his coöperation requested. Promptitude is however of moment and the physician in charge should make certain preliminary inquiries.

It is important, while the facts are fresh and defensive attitudes have not had time to develop, to make very careful inquiries about the food eaten by the sufferers. If there are a number of cases all subsequent to and seemingly related to a particular meal attention should be concentrated upon the exact constituents of that meal, the components eaten by *all* the persons who partook of it (sufferers and unaffected) with some general idea as to the amounts consumed. Frequently this preliminary inquiry will indicate with reasonable certitude the food at fault and elicit the fact that the sufferers were entirely confined to those who ate it.

Special efforts should be made to obtain some of this food, *as actually supplied*, for laboratory examination. This needs more personal trouble than is often given. It is not sufficient to merely ask for some of the food to be supplied. Many investigations have been handicapped by the fact that the food supplied for examination has not been the food as supplied but unconsumed, but has vaguely been part of the same food. It must be emphasised that only local or special portions may be infected and the rest of the food be quite sound. The fault may rest with meat gravy infected after preparation and standing, the meat from which it was made being perfectly good, and yet the meat alone is sampled. In some canned food outbreaks the writer has found that no steps have been taken to collect unconsumed scraps from the opened tin but that another tin of the same batch has been sent to the laboratory.

It is important to make a careful note of the physical conditions of the food before it is stale and decomposition changes may have started. The value of this examination is mainly on its negative side, since these cases often reach the courts and the physical condition of the food is an important point for the defendant. It is perhaps useful to point out that in the vast majority of food poisoning outbreaks (excluding botulism) the incriminated food is not noticeably altered in either appearance, taste, or smell when examined before secondary changes have developed. In botulism the food usually has a peculiar odour and taste, but sometimes appears unaltered. It is useful to note whether any domestic pets have eaten the infected food and have been ill.

After the presumptive food vehicle has been ascertained very detailed inquiries as to the source of infection are necessary. These are, however, very specialised, and for them the help of the medical officer of health should be invoked. They involve a careful study of the precise methods of preparation of the food, the conditions of storage after preparation, cleanliness conditions, the tracing and investigating of the original sources of the food, and the consideration of the possibilities of contamination from rats, mice, or other sources.

Laboratory Aids.

The laboratory is of undoubted value in the elucidation of food poisoning outbreaks, but there is a tendency on the part of the practitioner to attempt to throw all the onus of proof upon the pathologist. The intelligent coöperation of the clinician is necessary if satisfactory results there are to be obtained. The following three points are essential.

1. *Complete information must be supplied to the pathologist.*—In the first place, it is the bacteriologist, not the chemist, whose assistance s required, unless a definite chemical cause is suspected. It will be clear from the first article that the possible causes are very numerous. The practitioner must realise that the lines of investigation are essentially different for the different varieties of food poisoning. For living Salmonella bacilli the use of particular media is indicated, with serological tests; botulism requires a totally different bacteriological technique, chemical poisoning naturally requires a chemical examination, while to demonstrate *Salmonella* toxins in the absence of living bacilli is extremely difficult, often impossible. Unless the pathologist is fully informed by the clinician of all the facts he may lose valuable time and use up unrenewable food material upon investigations along the wrong lines. It will have been noted from the first part of this article how helpful is information about the symptoms, and how particularly useful are data concerning the incubation period. The different types of food poisoning all have different incubation periods.

2. *The right material must be submitted.*—Four classes of material throw light upon the causation—i.e.,

(*a*) *Any portions of the supposed peccant food.*—These must be actual portions remaining over (even scraps) from the food supplied which caused the illness. Frequently none is available.

(*b*) *Post-mortem materials from fatal cases.*—The spleen, pieces of liver, pieces of the small intestine, pieces of large intestine, and kidney are the most useful. To make a post-mortem examination and fail to submit the organs to bacteriological examination is for the most part a waste of time. When available this is both the easiest and the most reliable material on which to base a diagnosis as to the cause of infection.

(*c*) *Voided material from the cases.*—Specimens of fæces, and sometimes vomit, from the sufferers while in the acute stage, may give positive results, but are less useful than the other groups of material. In suspected chemical poisoning vomit material is particularly valuable.

(*d*) *Samples of blood for serological examination from the sufferers.*—One great advantage is that there is no urgency about these samples, since any serological reactions persist for many weeks, while in any case they will *not* develop until a week or more after the onset. The collection of these specimens, therefore, is better left over until the other samples have been sent and their examination started, which will enable the bacteriologist to indicate exactly what he requires. Classes (*a*) (*b*) and (*c*) must be sent without delay.

---

* Part I., on Causation and Clinical Problems, appeared last week.

3. *The material must be submitted properly.*—The directions of the writer, which have been adopted by the Ministry of Health, are as follows:—

Specimens of excreta may be sent in clean wide-mouth bottles. The food may be put in a clean tobacco tin. The organs from fatal cases should each be wrapped in a piece of clean cloth, wetted and wrung out (only damp, therefore) with 30 per cent. glycerin solution. All the organs may be placed so wrapped in one large tobacco or other tin. If possible, the samples should be sent packed in ice. An impromptu ice-box can be made by using a fairly large biscuit tin, and packing the tins and bottles in one side of this, and filling the other part with dry ice in small pieces. The tins and bottles must be secured from rolling about when the ice melts by means of cloths and wood partition, or other device. The biscuit box should be packed in a wood box with at least two inches everywhere of sawdust between the two boxes. If ice is not procurable the samples must be sent without it rather than be delayed.

The Interpretation of the Pathological and Chemical Data.

In cases of chemical poisoning the actual chemical agent responsible may be ascertained and an estimate arrived at as to dosage.

The analyst will supply information on the amounts present. A careful calculation is then necessary to ascertain whether this could represent a poisonous dose. Mere detection of a chemical poison does not necessarily imply that it was responsible. For example, in a case of botulism from canned fruit small quantities of tin may be found and be of no significance.

In *botulism* the pathologist may or may not be able to isolate *B. botulinus*, but he can often demonstrate, by animal experiments, the presence of botulinus toxin and ascertain the type of this bacillus responsible.

In *Salmonella poisoning*, if living bacilli are present, they can usually be isolated from the food, if any of it is available. They are never present in sound food. Fæces examinations, if collected during the acute stage or soon after, usually enable the bacillus to be isolated, but these bacilli tend to disappear fairly rapidly, and samples collected a week or so after recovery are often negative. In paratyphoid fever cultural blood examinations are often positive, but it is extremely rare for these to be successful in Salmonella food poisoning, and they are not worth doing.

With food poisoning from Salmonella toxins the laboratory report may be quite negative, since it is often impossible to demonstrate their presence in a articular outbreak; this is, however, possible in ome cases by special procedures. The diagnosis is then only a probable one based upon the whole of the facts of the outbreak.

In fatal cases the internal organs almost invariably yield the bacilli in outbreaks due to living Salmonella bacilli, and diagnosis in these cases is usually a simple matter.

Serological tests.—In many outbreaks no food is available, there are no fatal cases, and fæces samples are either unobtainable or obtained late and negative. In such cases the serological tests may furnish the only bacteriological clue. Inquiries have to be made as to the possibility of previous protective inoculations against typhoid and paratyphoid fevers, but apart from this it is rare for sera to give a positive reaction in any moderate dilution with any of the Salmonella strains. A positive reaction in a dilution of 1 : 50 or higher is therefore of great diagnostic value, and may be conclusive. While only a little blood, which can be withdrawn from the finger or ear in the ordinary way, is required, it should be more than the one or two drops which is often sent. It is quite easy to collect an adequate 0·5 c.cm. from the finger.

Fallacies.—There are a few fallacies to keep in mind as regards laboratory reports. If the food is of a meat type and is not submitted fresh the bacteriologist will find many bacteria and invariably *B. proteus*, because this organism is always present, in the writer's experience, in meat allowed to begin to decompose. The pathologist returns this in his report as present, but as such it means nothing. The presence of other strains such as *B. coli*, streptococci, &c., also cannot have significance under such conditions.

Conclusion.

In many mild outbreaks, from one cause or another, the bacteriologist's findings will be negative and the cause of the outbreak will remain obscure. These negative findings will decrease when fresher and better material is submitted and when our present knowledge as to causation is extended.

WILLIAM G. SAVAGE, B.Sc., M.D. Lond.,
Medical Officer of Health for the County of Somerset.

Special Articles.

RECENT WORK ON THE HORMONES OF THE OVARY.

OVULATION IN HUMAN BEINGS.

IT is not too much to say that nearly all the work on ovarian hormones during recent years is founded on the discovery of the cyclical changes in the vaginal epithelium which accompany the sexual cycle in small mammals. Stockard and Papanicolaou[1] first noted them in the guinea-pig in 1917, and the observation was later found to apply to the rat and mouse.

The implication of this purely biological investigation was grasped by Allen and Doisy,[2] who saw in this discovery the long-sought means of determining the activity of ovarian and placental extracts. Rats and mice were used for the experiments; their ovaries were removed, and smears from the vagina were examined microscopically. After oöphorectomy the sexual cycle is of course absent, and the rats remain in a permanently diœstral condition,* which corresponds with a characteristic histological appearance in the smears made from the vaginal epithelium. If an active preparation made from the ovaries or placenta is now injected into these animals, a cyclical change in the type of smear is produced, resembling that which occurs in the normal animal, and about 48–72 hours after the injection the leucocytes, accompanied by a few nucleated epithelial cells originally present in the diœstral state, have almost entirely disappeared and have given place to a cornified type of cell in which the nuclei are barely visible. These cells disappear as the time after the injection increases until finally the leucocytes and nucleated cells denoting the diœstral state are again preponderant.

Armed with this method of assay Allen and Doisy were able to consolidate much of the good work which had been done during the previous twenty years, and—what was no less valuable—were able to indicate the doubtful value of many investigations, which, in the absence of a reliable test object, had obscured the outlook and brought discredit on this branch of physiology. The result has been a tremendous development of research upon these lines in all countries. This work is mainly of two kinds: (1) the preparation of ovarian extracts of increasing purity, so that certainly less than 0·01 mg. is now necessary to produce œstrus in the rat—the ultimate object of this type of work is, of course, the isolation and chemical identification of the pure substance; (2) a study of the physiological and pharmacological properties of these extracts. Concurrently with these investigations some few early results of clinical tests have already appeared.

It may not be clear why so long an interval should have elapsed before this obviously very active substance should receive extensive clinical trial. The chief reason has been the nature of the early extracts, which were very crude and consisted of an insoluble oil hardly suitable for the purpose. More recently, however, the substance has been obtained by several workers independently in a water-soluble form of very high activity (Laqueur,[3] Jordan, Thayer, and Doisy[4]; Allen, Dickens, Dodds, and Howitt).[5] It still remains to be seen what will be the value of this material in medicine.

---

* The diœstrus is an interval between two periods of sexual desire in animals.

The Ovary and the Pituitary Body.

Meanwhile, research in another direction has been carried on by Zondek and Aschheim[6] in Germany and by Smith and Engle[7] in America. These authors showed independently and almost simultaneously that transplants of the anterior lobe of the pituitary body into immature female rats and mice produced very remarkable changes in the ovaries. Cornified epithelium appeared very soon in the vagina, and uterine hyperæmia, ovarian development, and the formation of large follicles or corpora lutea resulted. These effects are explained as due to the action of the anterior lobe hormone on the ovary, which is itself stimulated to produce its hormone or hormones, as in natural puberty. Ovulation may occur and many more corpora lutea than are normally found in these animals may be caused to appear. The anterior lobe hormone has no effect on animals whose ovaries have been removed.

These striking results, which are clearly of great importance, were followed by the remarkable discovery of Zondek and Aschheim that the anterior lobe hormone is excreted in the urine of women during pregnancy. The fact that the urine of pregnant women, and almost none other, when injected directly into immature mice, produces changes similar to those described above in the ovaries and uterus, has been made the basis of a biological test for pregnancy by Zondek and Aschheim, as has already been described in these columns.[8]

This work of the German and American investigators has clearly shown the relation long suspected to exist between the ovary and pituitary body. But there is probably more than one active principle contained in the anterior lobe of the latter gland, as is shown by the pioneer work of Evans and Long[9] in which they produced giant rats by injection of very concentrated extracts of ox pituitaries. Besides the growth-promoting principle we have also the hormone or hormones responsible for luteinising or ovulation, follicle-ripening, and also the production of local hyperæmia and the consequent formation of corpora hæmorrhagica, such as are obtained in rats by the injection of the urine of pregnant women. These last are so characteristic of the injection of urine—whilst gland transplants produce mainly follicular growth followed by ovulation and the formation of corpora lutea—that Engle[10] has recently questioned whether the derivation of the active principle in the urine of pregnancy from the anterior pituitary is really proved. This will evidently be difficult to settle with certainty, but on the information at present available it seems probable that Zondek's assumption is justified.

Fluhmann[11] has lately reported that bilateral oöphorectomy led to the appearance of anterior lobe hormone in the blood of 12 out of 10 women studied. The time which elapsed between operation and the test varied from 8 days to 13 years in the different cases. In several cases of sterilisation by irradiation, and in some cases of functional amenorrhœa, the reaction was also found to be positive. The same method as that employed by Zondek and Aschheim was used, except that the patient's blood-serum and not urine was injected. This work suggests that possibly further valuable modifications of this test of Zondek and Aschheim may be forthcoming, and that these may find useful diagnostic applications. Much more study of these important matters is necessary, and the increasing literature on the subject shows that it is already in progress.

The Time of Ovulation in the Menstrual Cycle.

Of a somewhat different nature, but equally remarkable, is the recent work of Knaus[12] from Prof. E. Knauer's clinic at Graz. In this case also the starting-point is from some purely biological researches, this time due to Hammond working with the rabbit.[13] As is well known, in the rabbit coitus is regularly followed by ovulation at a known interval of time. It is thus possible to bring about ovulation at any time in this animal, and it has been found that the presence of the corpus luteum is accompanied by the development of a considerable insensitiveness of the rabbit's uterus to the action of pituitrin. This change is recorded in vivo by filling the uterus with fluid and recording the uteric pressure as a kymographic tracing. The injection of pituitrin into an animal which has not ovulated produces an immediate contraction which is not obtained in the same animal after ovulation.

Knaus has used this new biological reaction in an attempt to solve the vexed question of the exact time of ovulation in the human female, and the result of his test is remarkable. He claims that it is possible to say with certainty that a normal woman with a regular four-weekly cycle cannot conceive during the first ten days or after the 18th day of the menstrual cycle—that there is, in fact, a physiological sterility during this period. This conclusion is contrary to what has been fairly generally accepted for many years, but such observations at least show the immense practical importance of studying the internal secretions of the ovary.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Pathological Research in Vienna.

Prof. Jarisch, who at present is the chief of the Pharmaco-Experimental Institute of the University of Innsbruck (Tyrol), is shortly to be appointed as successor of the late Prof. Paltauf, who was director of the Vienna Institute for General and Experimental Pathology. With the new director a new departure in the work of the institute is anticipated. Prof. Paltauf favoured research into morbid anatomy, whilst Jarisch will turn his attention more to pathological physiology and to biochemistry. Some time ago efforts were made to convert the existing pathological institute into an institute for experimental therapeutics, on the model of Ehrlich's Institute in Frankfort, but the plan had to be abandoned.

A new institute for cancer research is, however, shortly to be opened in Vienna. The necessary funds have been contributed by a generous grant by Mr. Childs, an American philanthropist, who sought and found cure from a serious malady in this city. The cancer institute will be directed by Dr. Edelmann, who has converted for this purpose a private nursing home and equipped it as a centre for experimental therapeutic research. It will be organised in connexion with the Federal Serotherapeutic Institute, and Prof. Jarisch and Dr. Pick, professor of pharmacology, and Dr. Edelmann will coöperate in the systematic study of cancer, and, it is hoped, will attract many foreign students to work out their problems in Vienna.

The Decreasing Birth-rate in Vienna.

The official report just published of the Austrian Board of Health for 1928 shows that the population of the Republic was 6,536,892 persons on Dec. 31st of that year. The number of living births amounted to 115,014; of deaths, 96,321. This means a slight increase of population for the whole Republic, but not for its capital. In Vienna the statistics show a surplus of 6411 deaths over births. In the current year the loss will be still greater since the first six months of 1929 show an excess of deaths over births, amounting to 5631. Vienna had, in 1914, a population of over 2,000,000, and in 1928 only of 1,862,470, and the loss is yearly more marked. The chief reason for the drop of the population figure, which is barely half what it was in 1913, is the decline of the birth-rate, for the death-rate is also constantly decreasing. One factor, the emigration from the capital to the country, plays a part which must not be neglected, but the chief reason seems to be voluntary birth restriction from economical considerations.

Trichinosis in Vienna.

At a recent meeting of the Gesellschaft der Aerzte Dr. Reitter demonstrated several cases of trichinosis which have lately been observed in this city. Eighteen cases of trichinosis in this country were reported in 1925 and 1926, and since then, according to Dr. Reitter, cases have been more frequent than is generally supposed. He recently discovered two more cases. One patient was a woman of 50, who was sent to hospital diagnosed as nephritis, because of swelling of the eyelids and face, combined with slight albuminuria. She ran a temperature of 102° F. and had intense pains in the legs, but no other symptoms. The diazo reaction was strongly positive, and eosinophilia was present. The fever disappeared after a week. An excision from the gastrocnemius muscle verified the diagnosis of trichinosis. The second patient was a woman aged 25, who came to the hospital on account of supposed sinusitis frontalis. This patient also had high fever (101·6°), a swelling of the eyelids, pains in the limbs, and a positive diazo reaction. The nose was found to be normal. After a blood count showing 17,500 leucocytes and 44 per cent. of eosinophiles, the correct diagnosis was easily reached, and verified by an excision from the gastrocnemius, where an enormous quantity of trichinellæ was visible. This patient was cured in 18 days. Dr. Reitter puts stress on the presence of eosinophilia, which is a cardinal sign. But one must look for other symptoms more easily detected by the general practitioner: pyrexia, with high temperature, œdema of the face, or at least of the eyelids, pains in the muscles, positive diazo reaction, and negative findings of other organs. Diagnosis is then easily verified by a blood count and microscopic examination of a piece of muscle. The only reliable prophylaxis against trichinosis is sufficient boiling of pork. In the discussion following Dr. Reitter's demonstration Dr. Weinberger emphasised the necessity of compulsory notification of trichinosis by veterinary inspectors, so that the sale of infected meat is made impossible. The centralisation of slaughtering in district slaughter-houses with inspection of the meat by qualified persons is necessary, besides the control of all foreign imported meat, as is done in some parts of Germany. Dr. Decastello pointed out that small outbreaks are certainly frequent, but pass unrecognised as "nephritis" or "rheumatism." He had observed that a swelling of the spleen is generally not noticeable, but the patellar reflexes are often absent (owing to injury to the muscles). The therapeutic measures consist in injections of salvarsan, trypaflavine, urotropine, but are not reliable. Some cases prove fatal from myocarditis or thrombo-arteritis.

Diffusion Anæsthesia of the Peritoneal Cavity.

Dr. Mandel, of the clinic of Prof. Hochenegg, has used lately a new method to anæsthetise the abdominal region, which he calls diffusion anæsthesia. Under local anæsthesia he opens the abdominal wall, inserts a drain, and pours into the peritoneal cavity 250–350 cubic centimetres of a ¼ per cent. to ½ per cent. solution of percain. This substance is a derivative of quinoline, and has nothing to do with cocaine. Its anæsthetic property is very high; it is active in a solution of 1:120,000 upon the cornea of the rabbit. Its action is superficial, but it has a high degree of penetration. Dr. Mandel has operated on 30 cases in this manner. A group of six cases consisted of exploratory laparotomy with absolute anæsthesia, the operations lasting up to one hour; a second group consists of five gastro-enterostomies with complete anæsthesia. No pain was felt even when the organs had to be handled and pulled. A third group comprises 15 gastrectomies. In three cases the method was a failure, perhaps owing to the fact that the solution used was old, not freshly made; the others were quite satisfactory. A fourth group is formed by four appendicectomies, and also showed very good results. Dr. Mandel uses pantopon before operation and adds adrenalin to the percain. No complication was noted, but further observations are necessary to decide the indication for this method.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Tuffier and the Chair of Surgery.

YOUR account of Théodore Tuffier (p. 993) does no more than justice to one who, as you say, upheld a great surgical tradition. Surprise has been expressed that he was never granted the full professoriate by the Paris Faculté, although he became agrégé in 1880, when he was but 32 years old. This appears the more remarkable, as in France at least great importance is attached to the status of professor, which is the key to most forms of hospital practice, as well as to the recruiting of assistants and pupils. The omission was due to personal and not professional considerations. Tuffier, however, had no need of official status; for many years his surgical service attracted every foreign surgeon passing through Paris, and his pupils are scattered all over the earth. He was a marvellous teacher, able to set out the hardest subject in clear language which impressed itself on the memory. As a surgeon he was rapid and skilful, often changing his methods, for he had no use for routine; each case was dealt with according to the findings of the moment. He was always ahead of his colleagues in trying every new operation, and stamping it with his own personality. You have spoken of his pioneer work in rachianæsthesia, but he was for some time the only surgeon in Paris to practice blood-transfusion by direct anastomosis of the radial artery of the donor to the saphenous vein of the recipient. It was, in fact, with some tremor that his assistants watched this operation, for once the anastomosis was performed, no one knew how much blood was passing, and whilst the recovery of the recipient might be dramatic, the operation had to be hurriedly stopped owing to the fainting of the donor. This was the way in which one of the most beneficent of therapeutic measures arose, and Tuffier's work was the prelude to the quick and simple process of present-day transfusion. In the social life of Paris, Tuffier took a high place. His judgment was always sound, and if adverse was couched in such a way as to appear almost indulgent. He was, besides, a great traveller.

Death of Prof. Lecène.

A second blow to surgery is the loss of Paul Lecène, who has died at the age of 51, as the result of typhoid fever contracted by operating on a case of cholecystitis. He passed rapidly through the earlier stages of a surgical career, and was made professor of clinical surgery in 1921. He was a man of wide culture, reading Greek as if it was his native language, and being one of the first authorities on morbid histology. He kept himself fit by outdoor sport, and was a practised boxer. His vast knowledge and robust character made him a formidable adversary at scientific meetings, but those who suffered at his hands had to admit his fairness and honesty of purpose. Several of his books on surgical morbid anatomy will rank as classics.

Euthanasia and Morphia.

A recent acquittal on a murder charge has revived interest in what is known as euthanasia, although it may be stretching a point to apply the term to the process of exterminating a suffering patient with several bullets from a revolver held in a hand rendered clumsy by emotion. The medical man has only to recall the tremor with which he applied the knife for the first time to the live skin of one of his fellows. Nevertheless, most doctors in this country would have voted as the jury did in the case of Richard Corbett, indicted for accelerating the death of his mother, who was suffering from a generalised cancer. A similar verdict has been given three times in the last five years. Euthanasia has been widely discussed here, and whatever may be its philosophy, it is a fact that the whole medical corps is opposed to its introduction into the law. One point made in court during the Corbett trial does not seem to have received the emphasis it deserves. Mrs. Corbett, although her suffering had been such as to bring a spectator of it to the verge of desperation, had been given no morphia. I do not know the reason for this in her case, but I do know intimately of a case in which a patient to whom the help of morphia was refused was killed by his wife, who was horrified at his suffering. It must be kept in mind that since the law on pharmacy, instituting what is called "*Tableau B*," came into force in 1916, chemists and physicians alike live in terror of morphia. Honourable practitioners have been brought before the magistrate for giving to agonised patients with cancer doses of morphia considered too high by an inspector of pharmacies. Some chemists actually prefer not to stock morphia at all, in order to avoid the annoyance of inspection. The law of 1916, which was framed with the laudable object of saving from the asylum a handful of wretched addicts, has set the terror of prosecution amongst physicians, and has condemned to helpless suffering thousands of patients who might have been relieved of it.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Civic Guard and the Protection of Children.

SPEAKING last week at the annual meeting of the Society for the Prevention of Cruelty to Children, General Eoin O'Duffy, Chief Commissioner of the Civic Guard of the Irish Free State, gave interesting information about the work done by the Civic Guard in carrying out the Acts for the protection of children. He drew attention to the frequency of infanticide in recent years, the number of cases reported in the five years 1924–28 being 80, with 50 prosecutions. He was not satisfied that the punishment of those guilty of infanticide was sufficient. It was sometimes difficult to get juries to appreciate the seriousness of the crime. The murder of infants was not placed on the same level as the murder of adults. During the same five years there had been 806 prosecutions under the Children's Act, and in the year 1928 there had been 11,042 prosecutions under the School Attendance Act. In many counties there had been no attempt to carry out the inspection of boarded-out children.

The Medical Society of University College, Dublin.

At the opening meeting for the session of the Medical Society of University College, Dublin, the president, Dr. D. J. Cannon, read an interesting address on the Relationships of Gynæcology to Endocrinology and to Other Branches of Medicine. He gave a clear account of recent researches on the mechanism of the menstrual function, and showed that there was reason to believe that not only the ovary, but also the thyroid and the pituitary were active in the stimulation or control of menstruation. He also discussed the relations of gynæcology to abdominal surgery and to psycho-analysis. The paper was discussed by Prof. R. J. Rowlette, Senator H. L. Barnaville, Prof. M. R. J. Hayes, Dr. D. G. Madill, and President D. J. Coffey, who occupied the chair.

Presidency of the Royal College of Surgeons in Ireland.

At a meeting of the Royal College of Surgeons in Ireland, held on Nov. 15th, Prof. Andrew Fullerton, of Belfast, was elected President in room of the late Prof. T. E. Gordon, who died last July. Mr. Fullerton is the immediate past-President of the College, having been in the chair from 1926 to 1928. He will now hold office until the annual election of the officers next June.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1928 statistics of two inland and three seaport towns:—

Name of town and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respirat. ry diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Leeds .. .. (476,500)*	16·1	12·9	1·13	1·16	2·1	2·0	79/37	31	4·6
Bradford .. (288,500)	15·3	13·6	1·00	1·52	2·6	1·6	69/31	25	5·4
Portsmouth .. (240,700)	17·2	11·3	0·95	1·31	1·4	2·2	55/23	26	5·4
Cardiff .. .. (227,000)	17·0	11·7	1·21	1·14	1·9	1·8	77/32	30	5·8
Birkenhead .. (159,200)*	18·5	12·3	1·23	1·48	2·2	1·9	80/34	40	5·5

* In both these cases the boundaries were extended on April 1st, 1928, and the Registrar-General gives a population for statistical purposes—viz., 474,800 for Leeds and 157,000 for Birkenhead.

The proportions of notified stillbirths to live births were: Leeds, 5 per cent.; Bradford, 4·5 per cent.; Cardiff, 6·4 per cent.; Birkenhead, 5 per cent.; and Portsmouth, not given.

Leeds.

Dr. Johnstone Jervis reports that by the extension of the boundaries on April 1st the area of the city was increased by 7060¼ acres to 38,100 acres, and the population by about 5000. The hours of sunshine were 1320·5 as compared with 1177 in 1927. A table shows that in 1928 Leeds occupied ninth place, equal with Manchester, for death-rate among the 13 large English towns, the towns with higher rates being Liverpool, Bradford, and Newcastle. Deaths from vehicular traffic accidents averaged about 60 during the past three years, as compared with about 20 in the three pre-war years. The practice of cremation gains ground very slowly in Leeds, the numbers for the last four years being 26, 14, 32, and 31, whilst the deaths in each of these years were over 6000.

Dr. Jervis hopes that the unification of the public medical services, consequent on the Local Government Act, 1929, will include the school medical service. There were 53 cases of small-pox without a death. Scarlet fever was extremely prevalent in the second half of the year. The cases notified, 3515, were more than in any previous year. The type was mild, and the deaths numbered 18. Dr. Jervis mentions that parents are slow to avail themselves of the facilities provided for the immunisation of young children against diphtheria. The need for complete immunisation of the staff of the isolation hospital is shown by the fact that 17 of the staff developed scarlet fever and 6 diphtheria. A marked increase of new cases of syphilis and gonorrhœa at the V.D. clinic is noted, succeeding the fall, which took place in Leeds in 1921–23. Dr. Jervis recommends that a trial be given to a scheme for boarding-out the child contacts of "open" cases of tuberculosis in a healthy environment. The "factory-in-the-field," for giving employment to consumptives in firewood-making, brush-making, and printing, is being continued. At the end of 1928 there were 35 tuberculous and 13 non-tuberculous employees. A striking example is given of the danger of tuberculosis being spread among clerks in an office. A junior typist was notified in March, 1927. In October, 1928, another junior clerk was diagnosed. The infecting case was a senior clerk with advanced disease, who was only referred to the dispensary in March, 1928. Artificial light treatment is found to be "of definite value" in tuberculous adenitis, bone and joint disease, and abdominal tuberculosis. Light treatment is also in use at two infant clinics, and is claimed to give good results in rickets, malnutrition, and general debility, for which ailments it is also found useful at the Infants Hospital, Wyther (50 cots). In February an orthopædic clinic was inaugurated for children under five years. Plans are being prepared for the much-needed new hospital at Elmet Hall, which will deal with orthopædics and surgical tuberculosis.

The chief veterinary officer, Mr. J. A. Dixon, M.R.C.V.S., reports that the cow population of the city was 2130 in the first quarter, and increased by 791 when the extension took place. Under the Tuberculosis Order 23 notifications were received from owners and 3 from veterinary surgeons, whilst 39 suspected animals were discovered by routine inspection of the cattle. This confirms the experience of previous years that the Order can only be effective where there is regular routine veterinary inspection. Of the 40 cows condemned 12 had tubercle of the udder, 15 tuberculous emaciation, and 13 were "otherwise" affected. A considerable number of the cowsheds in the added areas were below the standard in sanitation. The cooling of the milk is a difficulty, as many of the farms are without an adequate supply of water. The only Certified Milk herd in the city is that at the City Council's farm, and Mr. Dixon points out "that it would be rather difficult for farmers who recruit their herds by purchase of young stock, in the open market, as do the majority of the local farmers, to secure a regular supply of non-reacting cows."

The West Riding Smoke Abatement Committee has passed a resolution asking the Ministry to urge all the gas-works in the country to produce smokeless fuel by the low temperature carbonisation of coal. Since the war Leeds corporation have built nearly 6000 houses, but the housing of the man with an income of 35*s.* to 40*s.* "has not been touched." He needs a house with an inclusive rental of 6*s.* to 7*s.*, and a few municipal cottage flats are the only attempts to meet his wants. Each has a separate entrance, and they are very popular, and the demand exceeds the supply. It is intended to build more in future. Dr. Jervis also advocates the acquisition by the corporation of back-to-back houses of an intermediate type, to be let at low rentals to slum tenants, who, by being kept under supervision, "might be induced to keep themselves and their families in a fairly clean and healthy condition."

Bradford.

Dr. J. J. Buchan says there are 179 farms and 985 houses not connected to the corporation sewers. There are only 212 houses with privies, the remainder having water-closets, of which about 9 per cent. are of the "waste water" type.

Mr. W. Halstead, M.R.C.V.S., the veterinary inspector, states that there are about 3378 dairy cows stalled in the city, producing 7500 gallons of milk per day. Another 8000 gallons comes in from outside. The daily consumption of milk is given as 0·4 pints per head. As the result of regular inspection, 17 cows were found with tubercle of the udder and 15 otherwise affected with tubercle. Of 718 samples of milk examined, 39 were found to be tuberculous. In the follow-up of 15 outside tuberculous milks, 9 cows were found at nine farms with tubercle of the udder and slaughtered, whilst on six farms the source of the infection could not be traced. A milk purveyor, who failed to provide suitable storage accommodation for his milk and vessels, was convicted of selling separated milk, containing 29·7 per cent. of added water, and of neglecting to label his milk vessels with his name and address, and the words "separated milk," and was removed from the register by magistrate's order.

The Schick test is not employed in Bradford. There were 136 cases of small-pox with 4 deaths, all of old persons debilitated from other causes. It is claimed that the local powers for the compulsory notification of venereal diseases, obtained in 1925, have had a wholesome effect in causing cases to continue until recovered under treatment, either at the municipal centre or by private practitioners. In 1927 an investigation officer was appointed to follow up known cases of cancer, and, with the coöperation of the whole medical profession, it is thought that no case will be lost sight of. The follow-up of the 450 cases which came under treatment during 1928 shows how late cases of cancer come under medical observation. Of 153 cases notified by practitioners, 113 were too advanced for any but palliative treatment. Of 220 operations in hospital, a radical operation was not possible in 124, and in another 118 cases admitted to hospital no operation at all was possible. A table shows that during the last 20 years there has been a slow but quite marked decline in the neonatal death-rate, but that the mortality in the first week of life does not show quite the same improvement. Midwives attended 3157, or 74·4 per cent., of the registered births. Of these the municipal midwives attended 882. The total births were 4421. In the maternity wards of the municipal hospital there were 654 live births and 69 stillbirths, and 11 maternal deaths. The new patients, who attended the antenatal clinic of the hospital, numbered 700. The local authority conducts 11 maternity and child welfare centres, and the main effort of volunteers is to provide skilled instruction in dressmaking, sewing, knitting, cookery, and mothercraft by experienced teachers at four centres. A holiday home and convalescent fund are other features of the voluntary work.

The municipality erected 1260 houses, and at the close of the year 84 were in course of erection and 362 contracted for. There were also 247 private enterprise subsidy houses in course of erection at the end of the year. Nevertheless, many very serious cases of overcrowding come to light, and there is still a great scarcity of houses. On Dec. 31st, 1928, the applicants for new houses numbered 2126, of whom 483 were living in lodgings. The White Abbey improvement scheme is making progress; 95 per cent. of the properties have been acquired and 36 per cent. demolished. In November artificial light treatment was inaugurated at the new central school clinic, and, in order that an accurate opinion may be formed as to its value, exact details of the treatment, dosage, &c., with results, are to be kept, and will be given in future reports.

Portsmouth.

Dr. A. Mearns Fraser reports that diphtheria was unusually prevalent, especially in the last quarter. The notifications were 866 and the deaths 53, a case-fatality of 6·12 per cent. A table shows that there were few fatalities from diphtheria in Portsmouth from 1861 to 1880; in 1881 and 1882 there were 205 and 106 deaths respectively; 1899 and 1900 were again peak years with 120 and 104 deaths respectively; another peak occurred during 1911 to 1915, since which the annual deaths have averaged about 40, and varied from 18 to 66.

The municipal maternity home (14 beds), which is about to be replaced by a combined maternity hospital and child welfare centre in Fratton, admitted 255 patients for their confinements, and the weekly antenatal clinic conducted at the home was attended by 780 new cases, the total births being 4445. The insurance scheme by which expectant mothers pay a premium of 5s. for provision of medical assistance if required has been in operation for two years. In the two years before the scheme the claims for medical services amounted to £1550; in the two years of the scheme's operation the claims have amounted to £2250. Dr. Fraser states that during the two years of the scheme doctors were called upon to conduct the whole confinement in 13 per cent. of the insured cases, but only in 3·3 per cent. of the uninsured. There is an increase in the maternal mortality from childbirth, accounted for by 14 deaths from puerperal sepsis.

A satisfactory feature of 1928 was the large number of new houses erected, but the housing requirements of the population have not yet been adequately met. The municipality erected 220 houses and flats. There were also 429 subsidy houses erected by private enterprise, and £32,400 was advanced under the Small Dwellings Acquisition Act, 1899, for the financing of 73 houses. A start is to be made in getting rid of some of the worst slums in the city during 1929. During the year the selection of tenants for municipal houses was placed under the health department. This entailed the classification and placing in order of urgency of over 1500 applications. Preference is to be given to large families living under unhealthy and overcrowded conditions, but unfortunately a large number of these applicants have had to be refused because they were unable to afford the rent.

Portsmouth came off well with 1923 hours of sunshine, and in this connexion the low death-rate from respiratory diseases with influenza is noteworthy.

Cardiff.

Dr. Ralph M. F. Picken's report contains many special features of interest. Records have been kept of hospital cases of cancer of the breast and uterus since Jan. 1st, 1926, and of the rectum since Jan. 1st, 1928. Of 30 cases of cancer of the breast treated in 1926, 16 were alive at the end of 1928. Of 29 cases of cancer of the uterus treated in 1926, 5 were alive at the end of 1928. In 34 of the 55 cases of cancer of the female genital organs treated by operation during 1924 to 1928, the period between discovery and operation was six months or less, and the average period between the first operation and death was 10·5 months. Dr. Picken comments that although cancer involving the uterus is eminently suitable for operative or radiological treatment in its early stage, only one-third of 167 of such cases received this treatment.

The circumstances of three outbreaks of milk-borne diphtheria, involving 31 cases with no deaths, are described by Dr. C. J. McSweeney. The first outbreak of 13 cases was associated with an unrecognised attack in the farmer's daughter, who slept in the same room with her sister, who was a carrier. The second outbreak was associated with the farmer's daughter, who was a carrier, and in this case virulent diphtheria bacilli were isolated from lesions on the udders of cows, which were diagnosed by a veterinary surgeon as cow-pox. In the third outbreak of 11 cases a carrier was found among the milk roundsmen. In view of the reports from abroad, sera submitted for the Widal reaction since October, 1928, have been tested for agglutination with *Brucella melitensis*. In November one such serum gave a positive result, and the patient in question, after consultations, was decided to be suffering from undulant fever of the *Brucella abortus* type. Since this occurrence milk samples sent to the public health laboratory for other purposes have been examined for *Brucella abortus*, and three positive samples obtained from different animals on a farm in a neighbouring county. Dr. Picken makes the deduction that milk-borne undulant fever may be more prevalent in this country than has generally been supposed. Since June, 1925, pregnant women attending the antenatal clinics have been submitted to the Wassermann test. The results up to the end of 1928 show that of 1967 such tests, 61, or 3·1 per cent., were positive. All those who give a positive result are treated at the auxiliary V.D. centre for women and children.

Cardiff has no large insanitary areas, and slum clearance is not as big a problem as in many towns. A recent investigation has revealed approximately 100 "unfit" houses. Section 8 of the Housing Act, 1925, has proved invaluable in securing the removal of dilapidations, and, when owners have proved difficult, ground landlords have readily brought pressure to bear. Water-closets without flushing cisterns have become a serious problem, to deal with which new powers may be necessary. There are approximately 14,000 such in the city.

The school report shows that of 29 children attending the oral school for the deaf, 14 were born deaf; that zinc ionisation for obstinate ear discharges continues to give good results; and that the Greenhill open-air school (accommodation about 100) and the special classes for stammerers, both recently started, are giving very encouraging results.

Birkenhead.

Dr. D. Morley Mathieson shows the need for the revision of the graded milk scheme. To the man in the street "Grade A must be the best milk, whereas it is really third in the scale." Another matter requiring attention is the compulsory keeping of registers by dealers. During the year one Birkenhead purveyor, licensed to bottle Grade A (T.T.) milk, sold other milk under this guise, and had his licence revoked. Dr. Mathieson points out that the risk of such frauds would be considerably minimised if every retailer were required to keep a register of all graded milk bought and sold. Such a register is required at present for wholesale transactions. During the year 84 samples of milk were examined for tubercle, and nine gave a positive result. This is equivalent to 10·7 per cent. to be compared with 21·0 per cent. for the 1927 samples.

An amended scheme for the welfare of the blind has been prepared by the health committee and approved by the Ministry. Under the scheme the health committee becomes the responsible authority, comprehending within its sphere of activities all aspects of the work, economic, medical, social, financial, and educational (without prejudice to the powers and duties of the Education Committee). The special Blind Persons Act subcommittee, in addition to five members of the health committee, includes representatives of the Education Committee of the Board of Guardians and of the voluntary institutions for the blind in Birkenhead and Liverpool. Full particulars of the new scheme are included in the report. The blind persons coming within the scope of the Act on March 31st, 1929, numbered 219, 118 males and 101 females. None was under the age of 5, 8 were aged from 5 to 16, and 2 from 16 to 21. So far as could be ascertained the age of onset of blindness was below 20 in 62 of the 219 cases—viz., 0–1 year in 29, 1 to 5 years in 9, 5 to 10 years in 7, and 10 to 20 years in 17.

The total births numbered 2923, and the antenatal clinic was attended by 493 expectant mothers. Dr. Mary A. S. Deacon reports that in all 612 new cases attended the clinic. Of 168 who were in their first pregnancy, 4 suffered from venereal disease; of 325 in a later pregnancy, 12 had venereal disease; and of 119 who were not pregnant, 17 had venereal disease. Dr. Deacon is also in charge of the special V.D. clinic for women and children. For the purpose of health education Birkenhead joins in the scheme conducted jointly by the Merseyside boroughs, and Dr. Mathieson states that this campaign has been welcomed by the public.

INFECTIOUS DISEASES IN ENGLAND AND WALES DURING THE WEEK ENDING NOV. 9TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 172 (last week, 168); scarlet fever, 3389; diphtheria, 1743; enteric fever, 66; pneumonia, 1121; puerperal fever, 36; puerperal pyrexia, 94; cerebro-spinal fever, 9; acute poliomyelitis, 29; acute polio-encephalitis, 2; encephalitis lethargica, 16; dysentery, 6; ophthalmia neonatorum, 77. No cases of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Nov. 12th-13th was as follows:—Small-pox, 195 under treatment, 9 under observation (last week 173 and 8 respectively), scarlet fever, 2795; diphtheria, 2656; enteric fever, 98; measles, 304; whooping-cough, 113; puerperal fever, 34 (plus 19 babies); encephalitis lethargica, 123; poliomyelitis, 7; "other diseases," 22. At St. Margaret's Hospital there were 9 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (3) from enteric fever, 22 (5) from measles, 9 (4) from scarlet fever, 16 (3) from whooping-cough, 32 (6) from diphtheria, 78 (20) from diarrhœa and enteritis under two years, and 62 (7) from influenza. The figures in parentheses are those for London itself.

No deaths from enteric fever were reported outside London. No large town reported as many as 10 deaths from diarrhœa, the highest figures being Birmingham 9, and Manchester 8. Manchester and Oldham each returned 3 deaths from measles, Liverpool 4 deaths from whooping-cough, Birmingham 10 deaths from influenza.

The number of stillbirths notified during the week was 260 (corresponding to a rate of 38 per thousand births) including 47 in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. P. M. Rivaz is placed on the Retd. List with rank of Surg.-Capt.

The following appointments are notified: Surg.-Comdrs. S. R. Johnston to *Victory*, for P. and R.T. School; and K. A. I. Mackenzie to *President*, for three months' post-graduate course. Surg. Lts. S. Jenkinson to *Royal Oak*; N. J. U. Mather to *Repulse*; H. L. Belcher to *Daffodil*; and F. G. V. Scovell to *Dragon*.

ROYAL ARMY MEDICAL CORPS.

Capt. G. K. Maurice to be Maj., and remains secd.

Lt. G. M. Cooper relinquishes his temp. commn.

The undermentioned to be Lts. (on prob.):—Lt. A. N. T. Meneces, from Supp. Res. of Off., R.A.M.C.; Lt. E. J. Curran, who relinquishes his temp. commn.; F. R. Gedye; and J. E. Snow, who is secd. under the provisions of Art. 205, Royal Warrant for Pay and Promotion, 1926.

ARMY RESERVE OF OFFICERS.

G. F. Walker to be Lt.

TERRITORIAL FORCE.

The undermentioned Majs. to be Lt.-Cols.: W. H. Fisher, C. V. Bulstrode, H. M. Fort, W. F. Mackenzie, D. S. Sutherland, (Bt. Lt.-Col.) H. F. Wilkin, L. B. Cane, J. B. Stanley, D. W. Boswell, C. Corfield, J. Taylor, W. C. Gunn, G. H. Stevenson, S. F. Linton, W. F. Denning, N. M. Fergusson, J. E. N. Ryan, A. La T. Darley, A. J. Gibson, R. C. Clarke, A. C. Court, A. F. Lee, G. H. H. Waylen, and J. F. Edmiston.

Capt. A. H. Crook resigns his commn. and retains his rank.

Capt. D. C. Maclachlan to be Maj.

Lts. W. T. B. Joss and M. L. Sutcliffe to be Capts.

D. A. McM. Crawford (late Offr. Cadet, Edinburgh Univ. Contgt., Sen. Div., O.T.C.) to be Lt.

ROYAL AIR FORCE.

Flying Officer H. D. Humphreys (Temp. Lt., General List, Army) is promoted to the rank of Flight Lt. (Dental) on promotion of the rank of temp. Capt. in the Army.

RESERVE OF AIR FORCE OFFICERS.

The undermentioned relinquish their commissions on completion of service: Flight Lt. J. G. F. Heal and Flying Officer H. W. D. Mackenzie.

INDIAN MEDICAL SERVICE.

Temp. Lts. Abdul Majid Khan and Patit Paban Chowdry to be Temp. Capts.

The undermentioned retire: Col. J. N. Walker and Lt.-Col. J. W. Watson.

The undermentioned resign their temp. commns.: T./Capts. Ratan Kumar Misra (and retains his rank), Tabla Ram Birmani, Pritam Varialsing Karamchandani, and T./Lt. Henry Brij. Nath Swift.

NAVAL MEDICAL OFFICERS IN CIVIL HOSPITALS.

Time spent in civil hospital appointments before entry into the Service has hitherto only been allowed to count for the purposes laid down in the Regulations for the entry of Medical and Dental Officers, R.N., if it was of not less than one year's duration for medical officers, or six months for dental officers. It has now been decided to remove this limitation, and consideration will accordingly be given to the grant of additional seniority, &c., to officers who served in such appointments for shorter periods than those hitherto laid down as the minimum. It has also been decided that officers who are permitted to continue to hold civil hospital appointments after entry into the Service may, at Admiralty discretion, be allowed to count for similar purposes the time spent in those appointments, both before and after entry into the Service, subject to the proviso that the total period allowed to count will not exceed one year in all for medical officers or six months for dental officers. The revised regulations will apply to all officers entered for permanent service or transferred to the permanent list on or after July 1st, 1926.

DONATIONS AND BEQUESTS.—Mr. Roger Lewis, of Malberry House, Little Mill, Monmouth, left £500 each to the Pontypool General Hospital and the Royal Gwent Hospital, Newport.—Besides other bequests, Mr. Samuel Crabtree Helm, of Ilkley, left £2000 each to the Bradford Royal Infirmary, the British Empire Cancer Campaign, Dr. Barnardo's Homes, Liverpool University, Manchester University, and the Society for the Prevention of Cruelty to Children; £1000 each to the Alton Cripples' Hospital and College, the Halifax Infirmary, the Ilkley Coronation Cottage Hospital, Liverpool Hospital, the Royal Eye and Ear Hospital, Bradford, the Royal Institution for the Blind, Bradford; the Society for the Prevention of Cruelty to Animals, Saltaire Hospital, the Seamen's Hospital, Greenwich; the Yorkshire Home for Incurables, Harrogate; and the National Association for the Prevention of Tuberculosis.—Miss Charlotte Inston, of Oakhurst, Oxford-road, Moseley, Birmingham, left her residence and furniture to the Birmingham and Midland Free Hospital for Sick Children, £625 to the General Hospital, Birmingham, £500 to the Walsall Cottage Hospital, and £100 to the Birmingham and Midland Hospital for Women.—The Hon. Mrs. (Diana) Newton, of Portchester-road, Bournemouth, left £3000 to the Church Missionary Society for the English Hospital at Jaffa; the balance of a promised sum of £500 to the Derbyshire Royal Infirmary; £200 each to the Queen Victoria Memorial Home of Rest, Derby, and the Victoria and West Hants Hospital, Bournemouth; and £100 each to the Derby and Derbyshire Home for Females, and the Derbyshire Hospital for Sick Children.—Mr. Albert Charles Jones, of Bouncill Towers, Kenilworth, left £1250 to the General Hospital, Birmingham; £1250 to Queen's Hospital, Birmingham; and £500 to St. Dunstan's Hostel for the Blind.

Correspondence.

"Audi alteram partem."

THE CRAFT OF SURGERY.

To the Editor of THE LANCET.

SIR,—Prof. Tonks in his letter speaks of the craft of surgery and no one is better able to view surgery in this light. Being a distinguished artist himself, and having had a medical training, he knows that operative surgery is an art that requires a good deal of craftsmanship in the handling of tools.

The complete success of a surgical operation depends largely upon the experience, judgment, and dexterity of the operator and the facility with which it is carried out is a test of the operator's skill. Some training in this manual aptitude is aimed at in the operative surgery classes of the medical schools, where the student is first taught the principles of the art as illustrated in the classical operations. The pupil, however, can only attain to a limited degree of efficiency, for the cadaver imposes none of the restrictions and complications of the living. What is so often neglected, however, is instruction in the correct use of the common tools of surgery such as the chisel, the gauge, and the osteotome. It is surprising how many who, having passed through the schools, hardly know how to use the chisel. It is true that considerable practice is necessary to enable one to put these tools to their finer uses as anyone knows who has had experience in working on human bone with its varying density of texture in different individuals. But some attempt might be made to teach students the intelligent use of these instruments. The easy handling of tools is a distinguishing feature of the best craftsmen. That fine surgeon Arthur Barker, used to commend to the initiate the sewing of old kid gloves as an excellent practice for bowel stitching. And there is a world-famed surgeon abroad, almost unrivalled in the technique of a certain difficult type of bone surgery, whose skill is attributed to the fact that earlier in his career he was a considerable craftsman in wood. He is, of course, an extreme example of what can be attained by much practice with the implements of a craft. I am, Sir, yours faithfully,

A. ROCYN JONES.

Harley-street, W., Nov. 18th, 1929.

THE ACUTE VULVITIS OF LITTLE GIRLS: IS IT GONORRHŒAL?

To the Editor of THE LANCET.

SIR,—The contribution by Dr. E. Wordley in your issue of Nov. 16th (p. 1035) raises once more the question of the gonococcal nature of the acute vulvitis of infants and little girls. Is the diplococcus found in the discharge veritably a gonococcus? The astonishing rarity of ophthalmia as a complication is difficult to explain if virulent gonococci are present in the profuse discharge. That the discharge is infective and passes from one child to another is doubtless true, yet in my experience the frequency with which cases are detected varies directly with the energy with which the necessary examinations are made. For example, so long as the scare in the ward persists so long does the epidemic continue. It dies down only by the exhaustion of all concerned.

Many little girls are attending venereal departments of hospitals and undergoing prolonged local treatment. Some of them are gravely upset by the worry and anxiety of the whole business. Some lose weight, colour, and appetite, sleep badly, or have attacks of vomiting, entirely due to the nervous upset. Yet I have the feeling that like the leucorrhœal discharges of adult women, the persistence of the discharge is most intimately dependent upon the general health. With improvement in the general health, a discharge which may have been present for months will suddenly cease.

It would ease the situation, at present so distressing both for mothers and children, if the condition could be stated to be not venereal and not gonococcal. At present the position seems to me to be doubtful.

I am, Sir, yours faithfully,

H. CHARLES CAMERON.

Devonshire-place, W., Nov. 18th, 1929.

⁂ S. C. L. writes that Dr. Wordley's case has some points in common with one in his experience, in which a woman, aged 21, contracted a moderately severe urethritis and cystitis three weeks after her marriage. The infection was proved to be due to the coliform bacillus, and in our correspondent's view was an auto-infection dependent upon two factors: (1) the trauma of the initial coitus, and (2) an error of hygiene, the anus after defæcation being cleansed from the rectum towards the vagina, thus facilitating the infection of a part already made susceptible.—ED. L.

THE MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY, LIMITED.

To the Editor of THE LANCET.

SIR,—One must assume that Dr. E. F. Thomas's "reply" in your issue of Nov. 9th to Mr. Bowdler Henry's letter was not deliberately intended to mislead, but he obscures the issue, and the statements he makes are untrue. Not one of my resolutions "directly attacked" any of the recommendations of the board. Neither can Mr. Steadman's nomination for election by any stretch of the imagination be construed as an "attack" on the board's recommendation that the retiring directors should be re-elected since he was nominated three weeks before the board made any recommendations at all.

No, the board cannot make Mr. Steadman's candidature the excuse for sending out proxies. After the notices calling the annual general meeting had been issued, the board sent out a request for proxies in order to defeat my resolution fixing an age-limit for directors, and thus to keep themselves in office. This is the ethical question referred to by Mr. Henry, and I submit that this action of the board is discreditable.

I am, Sir, yours faithfully,

HARVEY HILLIARD.

Clarendon-place, W., Nov. 13th, 1929.

To the Editor of THE LANCET.

SIR,—In reply to Dr. Thomas I should like to say that my remarks were merely the expression of a spectator desiring to see fair play. As such, and in the absence of bitterness or hostile intent, they do not constitute an "attack." I am not concerned per se with the board's reception of Dr. Harvey Hilliard's resolutions; but I am concerned to see that any of us, all equal members in this Society, contesting a vacancy upon the board, shall be ensured an impartial attitude on the part of those fellow members, who, by election, constitute the board for the time being.

Last year, when Mr. R. J. McNeill Love contested a vacancy, the retiring member was compelled by decision of the board—and, as I think, rightly so—to send out his own proxies at his own expense. This year, under the shelter of a general proxy, issued sometime after intimation had been given that there would be a contestant, the board—wrongly as I maintain—took the interests of the retiring members under its (official) protection, making their battle its battle. Thus, using the Society's funds, they converted what should surely be a private contest into one of board *versus* contesting member. By so doing, whatever their intention to the contrary, they placed themselves in the discreditable position of appearing banded together to keep a newcomer out.

I am, Sir, yours faithfully,

BOWDLER HENRY.

Harley-street, W., Nov. 13th, 1929.

To the Editor of THE LANCET.

SIR,—By the courtesy of the Editor I have seen forward copies of the letters of Dr. Harvey Hilliard and Mr. Bowdler Henry with an intimation that if I so desired I might send a reply.

I have nothing to add to the plain statements I made in my previous letter, and I cannot see that anything I have said is affected by the assertions of Dr. Harvey Hilliard or the criticisms of Mr. Bowdler Henry, as continuity of directorate is an essential factor in the successful conduct of a business, and the success of the Medical Sickness Society is self-evident.

I am, Sir, yours faithfully,

E. F. THOMAS.

Oakley-street, S.W., Nov. 19th, 1929.

ROYAL MEDICAL BENEVOLENT FUND CHRISTMAS GIFTS.

To the Editor of THE LANCET.

SIR,—It has been the practice of the Royal Medical Benevolent Fund for many years to give a Christmas gift to each annuitant and some of the most necessitous of the grantees.

The annuitants, who are over 60 years of age, and the grantees are both deprived of those little amenities of life which the more fortunate of us enjoy. Many of our beneficiaries are alone in the world as their friends and relations have passed over, and consequently they will not receive any gift or extra comfort this Christmas. Last year the Fund gave to each 30s.; this meant an expenditure of £500. Many readers will wish that the recipients of this gift in former years should not be deprived of it this year. But unless I am favoured by a generous response to this appeal, our Funds will not allow of this gracious and friendly act.

Will every reader of this letter please consider if he or she cannot send to the hon. treasurer, Royal Medical Benevolent Fund, 11, Chandos-street, London, W.1, a Christmas donation. I shall be grateful whether the donation be large or small.

I am, Sir, yours faithfully.

THOMAS BARLOW,
President.

Nov. 18th, 1929.

THE SIGNIFICANCE OF VISCEROPTOSIS.

To the Editor of THE LANCET.

SIR,—Your leading article of last week tempts me to suggest a possible explanation of the greater incidence of abdominal invalidism in women. I offer it for what it is worth, since it has formulated itself rather as an impression than a true hypothesis supported by adequate evidence. It depends on the biological fact implicit in the statement that, whereas man possesses a sex organ, woman *is* a sex organ. In other words, the average woman is so completely adapted to one great biological function that her range of adaptation outside it is much less than that of the average man. In a woman of a constitutional inferior type that range may decline to zero and with it her capacity for sublimation. In such a case excessive repression or inadequate functioning result in a lapse into invalidism, the organism withering, as it were, from lack of the essential stimulus necessary to maintain it in health.

I am, Sir, yours faithfully,

Leeds, Nov. 18th, 1929. HARRY BEDINGFIELD.

INTERPRETATION OF FERTILITY TESTS.

To the Editor of THE LANCET.

SIR,—From Dr. Browdy's letter I gather that I did not make perfectly clear the fact that oligozoöspermia indicated a lowered fertility rather than an absolute sterility. Theoretically a man with one spermatazoon per cubic centimetre of semen is capable of paternity. Still less can a man with a count of 60,000,000 be considered sterile, although from the experience of Comber and Sanders he would appear to be much less likely to have children than one with a count of 100,000,000. I also "would hesitate to give a negative reply," I would merely state that a man with a count of under 60,000,000 showed a fertility below what is considered the normal.—I am, Sir, yours faithfully,

KENNETH WALKER.

Harley-street, W., Nov. 19th, 1929.

LATER BREAKFASTS IN HOSPITALS.

To the Editor of THE LANCET.

SIR,—Adverting to the annotation on p. 937 of your issue of Nov. 2nd, may I point out that the custom of not calling any patient before 7 A.M. has now been adopted in this hospital. For many years past it has been the practice for those occupying private rooms not to be awakened before this hour, and this practice has now been extended to all patients with satisfactory results. By a slight adjustment the hours of duty for the nursing staff have been reduced by this innovation.—I am, Sir, yours faithfully,

H. J. SAY.
Secretary, London Fever Hospital.

Liverpool-road, N., Nov. 13th, 1929.

SOUTHEND GENERAL HOSPITAL.—The Duchess of York last week laid the foundation-stone of the new hospital which is being erected upon a site exceeding 12 acres, given by Lord Iveagh, who has also subscribed £20,000 towards the cost of building and is, in addition, adding one-third to the amount subscribed during the present year. The first section, which will provide 100 beds towards the intended total of 400, will include two ward pavilions, a children's wing, an operating and electrical block, an administrative block, and a nurses' home.

RADIOLOGY AT THE CANCER HOSPITAL.—The House Committee of the Cancer Hospital, Fulham-road, last week approved of an advanced course in radiology which has been drawn up by the Medical Committee. It is stated that the course will deal with all aspects of the subject on a larger scale than has before been attempted in London. The course will begin on Jan. 21st, and will be continued on succeeding Tuesdays and Thursdays until April 10th. It will consist of lectures and practical work, with demonstrations in both laboratories and hospital. A new radiological block is to be built which will add about 70 beds, bringing up the total to nearly 200. There will be pay-beds for middle-class radium patients. These developments will cost £150,000 and the hospital is appealing for that sum.

SCHOLARSHIPS AT EPSOM COLLEGE.—A vacancy has arisen for a Leopold Salomons Entrance Scholarship of £50 a year, open to the son of a member of the medical profession either living or dead.

Those may apply (*a*) who were over 11 years and under 14 years of age on Jan. 1st inst; (*b*) who can show an adequate standard of education for their age; and (*c*) whose financial condition is such as to make it impossible or difficult to obtain an education at the College without the help of the scholarship.

A vacancy has also arisen for a Sir Walter Buchanan scholarship of about £38 a year. It is primarily intended for the sons of deceased or prematurely invalided officers of the Indian Medical Service, but failing any such candidates, it may be granted to the sons of medical men of purely British parentage who are in necessitous circumstances and who have practised medicine for at least five years in India. Forms of application for both scholarships may be had from the Secretary, 49, Bedford-square, London, W.C. 1. Applications must be forwarded before Dec. 4th.

Obituary.

THOMAS OPENSHAW, C.B., C.M.G.,

CONSULTING SURGEON TO THE LONDON HOSPITAL.

WE regret to announce the death of Mr. T. H. Openshaw, the well-known orthopædic surgeon, which occurred on Sunday last, Nov. 17th, in a nursing home, after a brief illness.

Thomas Horrocks Openshaw was born in 1856, a Lancashire man, but educated at the University of Durham and the London Hospital. He took the English Conjoint Diploma in 1884, being already L.S.A., and graduated in medicine at Durham in 1883. In 1886 he obtained the diploma of F.R.C.S. Eng., and the degree of Bachelor of Surgery at Durham, where he proceeded to the M.S. He was for a period demonstrator of anatomy at the London and in 1890 was appointed assistant surgeon. Nine years later he became full surgeon, a position which he held for no less than 27 years, being appointed consulting surgeon in 1926. From the beginning Openshaw was a strong personality at the London Hospital. A successful student, a good football player, and a simple nature which manifested itself in strong friendships and strong dislikes, he was inevitably respected on the one hand for his high qualities and on the other was universally known as "Tommy," proving how much his genial characteristics were appreciated. Openshaw had just become full surgeon to his hospital when the South African War broke out and he was appointed surgeon to the Imperial Yeomanry Field Hospital, later becoming P.M.O. at one of the hospitals in Pretoria. He was mentioned in dispatches and was awarded the C.M.G., and was for a time a prisoner in the hands of the Boers.

MR. OPENSHAW.

[*Photograph by Elliott & Fry.*

Although originally elected to the London Hospital as a general surgeon, Openshaw early in his career devoted himself to orthopædics and indeed founded the orthopædic department of the hospital. His accurate knowledge of anatomy, gained as a demonstrator for many years, stood him in good stead here, and he soon became recognised as an authority on the subject, his private practice in the later phases of his professional life being almost entirely orthopædic in character. It was in this connexion that he made for himself an enviable name after the European War. When this war broke out he was too old to serve abroad, but he was appointed consulting surgeon to the Eastern Command with the rank of Colonel, A.M.S., was elected surgeon to King Edward VII. Hospital, and later was attached to Queen Mary's Hospital, Roehampton, where he became senior surgeon and where his special knowledge was of the utmost value to many wounded soldiers. No one who was ever present at the demonstrations which Openshaw would give of the manner in which many exhibiting grave anatomical defect would respond to his invitation to show what they could do with the aid of surgical appliances, can ever forget the scene. It has been described as resembling a ring-master supervising a circus performance, where the performers themselves seemed to enjoy playing their part.

Openshaw, though so enthusiastic about, and well-versed in his specialty, wrote no treatise on this or any surgical subject, but he acted for a time as joint editor of the Catalogue of the Pathological Museum of the London Hospital. He served for an extended period—namely, 1916 to 1924, on the Council of the Royal College of Surgeons, but took no prominent part in medical politics. His medical interests, however, were numerous, for he was consulting surgeon to the Royal National Orthopædic Hospital, the Poplar Hospital for Accidents, and the Cottage Hospitals of Tilbury, Sidcup, and Woolwich, while he was also surgeon to the Royal Surgical Aid Society. His military inclinations were pronounced, for as a lad he had been a keen Volunteer—he held a commission as Surgeon-Lieutenant in the Volunteer Medical Staff Corps when he went to the South African War—he became a Lieut.-Colonel to the Lincolnshire Yeomanry, and received the Territorial Decoration. For his services in the European War he was created C.B. He was a prominent Freemason and had been Master of the Shipwrights Company.

Openshaw married in 1890 Gertrude, daughter of Mr. William Pratt, of Bruern Abbey, Oxford, who predeceased him by a few months. A daughter survives him, but his other child, Major L. P. Openshaw, was killed in a flying accident in the summer of 1927.

SIR ARCHDALL REID, K.B.E., M.B., C.M. EDIN., F.R.S.E.

WE regret to announce the death of Sir Archdall Reid, the well-known authority on heredity, which occurred on Monday last at Southsea, where he had resided for practically the whole of his professional life.

George Archdall O'Brien Reid was born in India, at Roorky, his father being an officer in the Bengal Native Infantry. He received his medical education at the University of Edinburgh, and graduated M.B., C.M., in 1881. But he did not settle down to medical practice until he had undergone varied experiences as a game-hunter, school-master, and prospector, travelling in this way extensively in the Pacific and America, returning also to India and visiting New Zealand. In 1887 he came to reside in Southsea, where he remained until his death.

Throughout his long years of medical practice in one place Reid devoted himself to the study of heredity, basing his long and important treatises and his many public controversies alike on his intimate acquaintance with pathological conditions in a large town and his varied knowledge of primitive life and tropical pathology, while his knowledge was perpetually reinforced by acute and ruthless study of the great literature of the subject. It is as an authority on heredity that he will be remembered, and seeing how essentially the study of heredity is bound up with the study of the passage of time, it is somewhat remarkable that his strongly held views should to a great extent have been contained in a book which he wrote, over 30 years ago, entitled the "Present Evolution of Man." He was young to grapple in a considered volume with the central ideas implied in the word evolution, but he showed at once that he had gained a clear insight into the main hypotheses and was able to judge between them; he was critical whether he was follower or opponent, and could bring independent thought [illegible] to support independent views. His insistence on the predominant influence of education and example went to support his broad inference, at the time much challenged, that most if not all the mental qualities exhibited by man and characterising more especially different races were due to a transmission of the power or capacity for acquisition which had been gained and was not inborn; and in reference to the part played by evolution in a struggle for existence against zymotic disease, he held that, while in the process of time susceptibility to a disease might lessen as the attacks of pathogenic organisms might increase, he brought forward many-sided evidence to support his view that a growing racial immunity would accompany in a satisfactory manner a dying-off of the weaker members. On the question of alcoholism he declared that "if the world is to become more temperate it must be by the elimination not of drink but of the excessive drinker," thus on his first appearance as an author stating what may be termed the principle which in his future writings and controversies he upheld.

In 1901 he published "Alcoholism: A Study in Heredity," an expansion of these views, and a consideration of the phenomena of national drunkenness by the laws of biology, finding the action of alcohol on the race closely analogous to that of the zymotic diseases. Put briefly, this implied that the nation which had not at any time developed national drunkenness would be liable to massive risks from alcohol, which would not be incurred by nations which had passed through stages of national abuse into temperance. The theory was ably advanced and Reid's powers of argument made him an extremely difficult opponent, but he was attacked vigorously by the advocates of legislation against national intemperance, and the controversy, as it appeared in our columns, makes informing reading which is sometimes quite amusing.

In 1905 Reid published the "Principles of Heredity," undoubtedly impelled to do so by the varied nature of the opposition which his previous work had stirred up. He did not confine himself to the subject of heredity, but essayed the ambitious task of unfolding a complete scheme of biological evolution. The work was distinguished alike by incisiveness of diction, originality of thought, and cogency of argument, and it formed, directly and indirectly, a vigorous plea for the education of the public, especially the young, in the subject of heredity. For Reid held that, with the exception of a few organic instincts, man's mental equipment and much of his physical character are essentially acquired, and his message throughout was that proper education in biology was needed to rear a race of capable citizens. His last work was the outcome of the honest efforts and the sincere thinking of one who during the war had realised the dimensions of the menace of venereal disease. His book, "The Prevention of Venereal Disease," was not, and was not intended to be, an impartial statement. Alike from personal experience, the digestion of many reports and conversations with many authorities, he came to the conclusion that the application of simple antiseptic measures ought to be available, and that their use ought to be insisted upon, holding that instruction should be made public, and that neither the fear of infection nor the fear of the pulpit could be relied upon as deterrents.

Sir Archdall Reid married Florence, daughter of Lieut.-Colonel John Mahony, and she predeceased him. He was created K.B.E. in 1919.

CHAS. HAMILTON WHITEFORD, M.R.C.S. ENG.

Mr. Hamilton Whiteford, whose death on Nov. 13th is reported from Plymouth, was well known as a surgeon in the neighbourhood, and came of an old Plymouth family. He was educated at Plymouth College, at that time known as the High School for Boys, and completed his medical education at St. Bartholomew's Hospital. On qualifying in 1892, he took up house appointments at Coventry, and then returned to his home town as resident at the South Devon and East Cornwall Hospital, where he afterwards became honorary anæsthetist. Though he never had an extensive practice he was a capable surgeon, and spared no pains in the study of his profession. He took a lively interest in keeping abreast of the latest methods and put them into practice with care and thoroughness. A somewhat brusque and outspoken manner was only a veneer over a genuine and kindly nature. Those who knew him well were aware of many acts of sympathy and self-sacrifice. Mr. Whiteford was an active member of the Plymouth Medical Society, where his shrewd and outspoken criticism was keenly appreciated, and enlivened many an otherwise featureless discussion. Until his sight became impaired he was an excellent all-round athlete, and at one time was one of the most competent lawn-tennis players in the West of England. His death will be widely regretted, and especially by those who knew him best.

BRIAN MELLAND, M.D. LOND., M.SC. MANCH.

DR. BRIAN MELLAND.

Dr. Melland, who died at his home at Bowdon on Nov. 14th after a short illness, was representative of the best type of practitioner and was responsible for introducing one of the most effective remedies yet available for asthma. Born in Manchester, he was the son of Dr. Frederick Melland, who came to the city in 1839 and studied and practised medicine for the long period of 73 years till his death in 1911. Brian Melland was educated at the Manchester Grammar School and the Owens College, and became Doctor of Medicine of London University and Master of Science of the Victoria University. He held hospital appointments at the Manchester Royal Infirmary and the Children's Hospital. As a student he showed great promise in research work and if his health had been good might have made his mark in the world of science. His work on the histology of striped muscle-fibre, published in 1884, revealed him as a man with original ideas, and a paper published in our own columns in 1910 on the treatment of spasmodic asthma by the hypodermic injection of adrenalin introduced to us what is still perhaps the most potent drug in that complaint. In his younger days Melland, like other members of his family, was a sound athlete in various games but especially in tennis and lacrosse. In the latter game he played for the North and was picked to represent England. An attack of acute rheumatism prevented him playing and a further attack made it advisable that he should go abroad. He settled, therefore, in Grand Canary where he practised for about ten years. His account of the Canaries (*Medical Chronicle*, 1897) is one of the best that has been written. On his return to England he settled in Bowdon, joining the late Dr. W. Owen Jones in practice, and here he remained till his death, winning general affection and respect. He was twice married, first to Florence Trevor-Roper, and secondly to Kathleen Oliphant. His two sons were both killed in the war and he leaves a widow and five daughters.

DANIEL MARTIN BADEN EVANS, M.B., M.R.C.P. LOND., F.R.C.S. ENG.

AT the age of 29 Mr. D. M. B. Evans died on Nov. 9th of septicæmia following a slight injury on the football field. At the time of his death he was surgical registrar at Charing Cross Hospital, where he had received his clinical training. He entered the hospital from Cardiff Medical School in 1921, qualified two years later, became a Member of the Royal College of Physicians in 1926, and a Fellow of the Royal College of Surgeons last year. His career as a student brought him many prizes, and he sought a wide experience in appointments after graduation. These included work as resident medical officer at Queen Mary's Hospital for Children, Carshalton, and at the Bolingbroke Hospital, as senior house surgeon at the All Saints' Hospital for Genito-urinary Diseases, and demonstrator of anatomy at King's College. "By his death," writes Mr. Norman Lake, "Charing Cross Hospital has lost one of its most brilliant students of recent times. For the past two years he had identified himself very closely with the work of the hospital while he held the post of surgical registrar; indeed, it was probably his keen and constant application to the duties of that post which so reduced his resistance as to render him a ready prey to the septicæmia which so rapidly and tragically caused his end. His great ability was obvious to all, and the future had much in store for him. The hospital, the whole profession, is the poorer for the loss of a life so full of promise—a skilful surgeon, a lucid teacher, a musician, and a sportsman."

WE have to record the death of Dr. MATTHEW WILLIAM GAIRDNER, on Oct. 11th, at the age of 79. His father, Dr. Matthew Baillie Gairdner, of Crieff, had seven sons, of whom Matthew was the third. He took up medical study at Edinburgh in 1867, and was one of Lister's dressers. On qualifying as L.R.C.S. Edin. in 1871 he held house appointments at the Royal Infirmary, the Chalmers Hospital, and elsewhere, serving under such distinguished men as *Annandale*, *Heron Watson*, *George Balfour*, and Halliday Douglas. After work as a ship's surgeon and in India he settled in Naples, where he practised for the rest of his professional life. Dr. Gairdner's only remaining brother is Dr. James Gairdner, of Crieff. His son is on the resident staff of the London Hospital.

Dr. FRANK HERBERT SHAW, who died at St. Leonards-on-Sea on Nov. 11th, was a well-known medical practitioner in St. Leonards and Hastings. For over 40 years he was actively associated with the Buchanan Hospital as surgeon. A son of Dr. Archibald Richard Shaw, of St. Leonards, he was born in London in 1858. He studied medicine at King's College, completing his training at Guy's Hospital and in Germany, and became M.R.C.S. in 1881. He first went into practice at Chester, but after a time returned home to assist his father. There were few organisations in Hastings and St. Leonards with which Dr. Shaw was not in some way connected. He was at one time a keen Volunteer, and for a period was surgeon-captain to the old 2nd Cinque Ports Garrison Artillery. Twice married, he leaves a widow and two sons and two daughters.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

ANNUAL HOLIDAY BILL.

ON Friday, Nov. 15th, in the House of Commons, Mr. WINTERTON moved the second reading of the Annual Holiday Bill which, he said, provided that every employed person should be entitled to an annual holiday of not less than eight clear consecutive days on full pay. If any attempt were made to evade the provision with regard to the payment of wages, either by the dismissal of the workman or by his suspension immediately before the annual holiday became due, the penalty on conviction was a fine not exceeding £20. The Bill contained a provision against contracting out by arrangement between the employer and the workman, while in the case of the fixing of wages by piece-work rates it was provided that that should be arranged by regulation. The annual holiday was not in any way to interfere with the existing rights of anyone to the customary bank or other holidays, and it was made clear that the eight days were additional to any rights enjoyed under existing law. An employed person was defined as anyone employed under a contract of service or apprenticeship, and that would cover all the approximately 12,000,000 employed persons in the country. At present 3,000,000 persons enjoyed the privilege of at least a week's holiday with pay, and the Bill would add another 9,000,000. The measure was opposed by certain Members of the House because it was suggested that it would place a burden on industry. But an annual holiday surely meant improved health, and that must mean increased efficiency, which in turn would mean increased output and production. The Bill would have the effect also of bringing more people into employment, and would help the seaside resorts.

Mr. J. HUDSON seconded the motion for the second reading.

An Amendment.

Captain HUDSON moved the following amendment:—

> "This House declines to proceed with a Bill which materially affects every phase of industry, agriculture, and commerce, which interferes with the long-established custom of employers and employed to settle conditions in their own industries, and which is consequently of so far-reaching a character that this House should not entertain it unless it is presented by a Government which is in a position, after full consultation with all interests concerned, to give the House authoritative information on the cost and effects of the proposal and the measure of agreement thereon throughout the industries affected."

He said that he and the other Members of the Conservative party were opposed to the Bill, not because it was bad in principle, but because they believed that in its present form it would have such an upsetting effect upon industry that it would do more harm than good. The mining industry had worked out the cost as being something like £2,250,000 a year, which was estimated to be equal to 2½*d.* per ton of coal. The country was, he believed, moving along the lines of a universal holiday for all workers, and he did not think there was a single Member of the House who was opposed to that, but this Bill would not, in his opinion, bring that about. In any case, a proposal of this kind should be made, if it was to be made at all, not in a private Member's Bill but in a Government measure.

The View of the Government.

After some debate,

Mr. LAWSON (Parliamentary Secretary to the Ministry of Labour) said that the Government accepted the principle of the Bill, but was conscious of the fact that the matter could not be dealt with in such simple terms as it proposed. They felt that there was some need of consulting the industries of the country before anything on a big scale was done. In view of the heavy programme of Parliamentary business, the Government could give no real guarantee that time would be found for its further stages if the measure obtained a second reading. The Government hoped, however, that the industries concerned would assist in the spread of the desirable practice embodied in the Bill.

After the closure had been carried by 184 votes to 63, the amendment was negatived without a division, and the Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 14TH.

Hospital Accommodation for Rhodesian Miners.

Sir ALFRED KNOX asked the Under Secretary of State for the Colonies the present estimated numbers of Europeans and Natives, respectively, at present employed on the copper mines of Northern Rhodesia; what hospital accommodation for these employees was now provided, and where; whether any new schools were now being built to provide for the education of children of employees in these mines; whether any new legislation regarding safety and workmen's compensation had been passed to protect workers in these mines; and whether he would require the furnishing of regular reports on all casualties similar to the returns required from the mines in the Gold Coast.—Mr. **Lunn** replied: For the whole industry, natives 14,883, and Europeans 1118, well-equipped hospitals are now available at the established mines, and are being provided at mines in the development stage. Educational questions and revision of existing protective legislation are under consideration. Regular casualty reports will be required.

THURSDAY, NOV. 15TH.

Charges of Indecency in Hyde Park.

Mr. **Day** asked the Home Secretary the number of charges of indecency brought by the police under the Hyde Park regulations during the months of July, August, and September, 1929; and in how many cases was the police evidence supported by that of private persons.—Mr. **Clynes** replied: The number of charges of indecency brought by the police under the Hyde Park regulations was three in July, seven in August, and five in September. In only one case was the police evidence supported by that of private persons.

Silicosis.

Mr. **Hannon** asked the Home Secretary, in connexion with and in view of the wide scope of the Various Industries (Silicosis) Scheme, 1928, if he would indicate the precise industries, other than the manufacture of pottery and scouring powders and the processes in these industries, in which he had had definite evidence of silicosis, disabling silicosis, or death from silicosis, or of any of these accompanied by tuberculosis, and their number.—Mr. **Clynes** replied: The following are the particulars (so far as it has been possible to trace them at short notice) of ascertained cases of silicosis which have come during the last three or four years to the knowledge of the Factory Department or the Mines Department in the particular industries or processes covered by the Various Industries Scheme, excluding the potteries and the manufacture of scouring powders: One case in each of the following industries or processes—sand-grinding (iron foundry); silica milling (silica flour manufacture); stone crushing (road making); tin mining; and lead mining; two cases in millstone dressing (corn milling); four cases in sandblasting (metal works); ten cases in stonemasons' work; and 25 cases in coal mining. These cases are mostly fatal cases where the cause of death was ascertained through a post-mortem examination ordered by the coroner, and they must not be taken as affording any criterion to the incidence of the disease in the industries or processes concerned or as representing the whole or even the main part of the experience on which this scheme is founded. It must be borne in mind that the disease is not notifiable as other industrial diseases are, and that, as pointed out in the recent report of the Committee on the Medical Arrangements for the Diagnosis of Silicosis, the diagnosis of this disease involves expert examination which has not been generally available. As a consequence, except in those industries under the Refractories Industries Scheme in which special arrangements for expert examination have been instituted, the disease has not been diagnosed as such, but has been set down as some other form of disease of the respiratory system. The disease has, however, been the subject of extensive medical research for a number of years, and much experience has also been gained through the periodic examinations carried out under the Refractories Industries Scheme, and I am advised that the result has been to show conclusively that wherever workmen are subject to certain conditions of exposure to silica dust, they incur a substantial risk of the disease and, in fact, wherever any special inquiry has been held into any process giving rise to such conditions, silicosis has been found to be present to a serious extent. For instance, the inquiry into the sandstone industry in 1928 showed that out of 464 workmen examined 112 were found to have contracted silicosis. The honourable Member will understand, therefore, that in selecting the industries and processes for inclusion in the Various Industries Scheme, regard was necessarily had not only to the ascertained cases of silicosis but also to the degree to which the workers would in fact be liable to be exposed to silica dust in the particular circumstances of their employment.

Medical Referees and Workmen's Compensation.

Mr. **McKinlay** asked the Home Secretary the number of cases submitted to the medical referees under the Workmen's Compensation Act during the past three years in Glasgow, Edinburgh, and Dundee, and the number of such cases decided in favour of the injured persons.—Mr. **Clynes** replied: The number of cases referred were as follows: At Glasgow 179 in 1927, 210 in 1928, and 205 in 1929; at Edinburgh 114 in 1927, 166 in 1928, and 147 in 1929; at Dundee 37 in 1927, 16 in 1928, and 19 in 1929. The information asked for in the last part of the question is not available.

Gifts and Inducements and Panel Prescriptions.

Sir **Kingsley Wood** asked the Minister of Health whether he proposed to make any alteration or amendment in the Medical Benefit Regulations relating to gifts or inducements by chemists of coöperative societies concerning National Health Insurance prescriptions.—Mr. **Greenwood** replied: The matter is engaging my consideration.

Proposed Raising of Insurance Income Limit.

Mr. **D. G. Somerville** asked the Minister of Health if he would consider appointing a committee to investigate the question of raising the present limit of £250 entitling participation in the National Health Insurance Act to a higher figure more consonant with the existing cost of living.—Mr. **Greenwood** replied: I will see that the matter is brought to the notice of the committee which is engaged in a survey of the schemes of social insurance.

Local Authorities and Blind Persons.

Mr. **Tillett** asked the Minister of Health the number of local authorities who had made arrangements for promoting the welfare of blind persons under the powers conferred upon them by the Blind Persons Act, 1920, Section 2.—Mr. **Greenwood** replied: Such arrangements have been made by all the 146 local authorities under the Blind Persons Act.

Application of Artificial Cream Act.

Mr. **Lawther** asked the Minister of Health if his attention had been called to the proceedings at Marlborough Street police-court on July 2nd and 12th, and the subsequent appeal at the London sessions on Sept. 13th, when it was decided that the Artificial Cream Act could not apply as the case had not been brought forward by an official of a local authority but by an outside authority; and if he would be prepared to bring forward legislation empowering individuals to seek protection under the said Act where county or borough councils failed to carry out their statutory duties.—Mr. **Greenwood** replied: I am aware of the proceedings referred to by my hon. friend, but I cannot undertake to introduce amending legislation on this subject at the present time.

Open Spaces in London.

Captain **Austin Hudson** asked the Minister of Health whether he was aware that certain recreation grounds, playgrounds, and open spaces in London were being closed in order that local authorities might utilise the sites for building purposes; and whether, in view of the increasing need for such open spaces in towns and cities, he could take any steps to deal with this matter.—Mr. **Greenwood** replied: I am not at present aware of any case where in London a public recreation ground, playground, or open space has been closed for building. If the hon. Member will give me particulars, I shall be glad to make inquiries.

Vaccination and Small-pox.

Mr. **Freeman** asked the Minister of Health whether his attention had been called to the deaths of five children within one month following vaccination—viz., Terence Kellaher, 5 months, vaccinated August 14th, died Sept. 15th; Ronald Whitehouse, 5 months, vaccinated August 23rd, died Sept. 5th; Leslie Brower, 6 months, vaccinated Sept. 11th, died Sept. 18th; Frederick Wright, 11 years, vaccinated in March, died Sept. 12th; and Jackie Balshaw, 4 months, vaccinated Sept. 12th, died Oct. 1st; and if he would institute inquiries as to whether vaccination was one of the contributory factors in the deaths of these and similar cases.—Mr. **Greenwood** replied: My attention has been called to two of the five deaths referred to which occurred in London, Blackburn, Bolton, West Bromwich, and Somerset. In neither of these two was vaccination one of the certified causes of death. In both cases post-mortem examinations were made and inquests held, and the deaths were found to be due to causes entirely unconnected with vaccination. I have no information as to the remaining three cases beyond the death certificates which show that in two of them post-mortem examinations were made, and in none of the three was there any reason to think that vaccination contributed in any way to the fatal issue. As regards the last part of the question, I may say that all cases in which death is stated to have resulted directly, or indirectly, from vaccination, are reported to my department by the Registrars of Births and Deaths, and are made the subject of investigation.

Mr. **James Gardner** asked the Minister of Health the number of deaths in respect of which the death certificate included the word vaccination, or vaccinia, or vaccine, or similar words, registered during each of the last six months for which figures were available.—Mr. Greenwood replied: The number of deaths are as follow: April, none; May, 4; June, 3; July, 4; August, 5; and September, 1. These figures include two deaths in which the words "vaccination" or "vaccinia" did not appear on the medical certificate or coroner's certificate, but which, on inquiry by the Registrar-General, were stated to be associated with vaccination, and one case in which the word "vaccination" appeared on the medical certificate in the form of a positive denial that the vaccination had any connexion with the death.

Approved Societies and Ophthalmic Treatment.

Dr. Morris-Jones asked the Minister of Health how many approved societies under the National Health Insurance Acts provided facilities for optical and/or ophthalmic advice and treatment for insured persons; whether there were any approved societies that did not provide such facilities; and, if so, whether he would give the names and numbers of such societies.—Mr. Greenwood replied: Consequent upon the second valuation, 5883 societies and branches in England and Wales, comprising nearly 12,000,000 members, have made arrangements to provide ophthalmic treatment, including the provision of optical appliances, as an additional benefit; 1156 societies and branches, with about 1,700,000 insured members, do not provide this benefit, generally because their surpluses have been used for other benefits. I cannot undertake to give the names of these societies and branches.

Approved Societies and Dental Treatment.

Dr. Morris-Jones asked the Minister of Health how many approved societies under the National Health Insurance Acts provided or contributed towards dental treatment for insured persons; whether there were any approved societies that did not provide or contribute towards such treatment; and, if so, the number and names of such societies.—Mr. Greenwood replied: The number of approved societies and branches in England and Wales which contribute towards the cost of dental treatment of their members as an additional benefit is 6645, covering 12,727,000 insured members. Only 494 societies and branches, with approximately 900,000 members, are not in a position to give dental benefit, either because they selected other additional benefits, or because they had no available surplus. I cannot undertake to give the names of these societies and branches.

Plague in British India.

Major Graham Pole asked the Secretary of State for India the number of cases of and deaths from plague in British India in each of the last five years; and whether any progress was being made in India in respect of the methods of effectively dealing with this scourge.—Mr. Wedgwood Benn replied: I have no reliable figures of cases. Plague figures have shown on the whole a marked decline in recent years. Research work on prophylactic methods has yielded valuable results, but I am advised that there is not yet any reliable treatment of the disease. Progress depends largely on the willingness of the people to coöperate with the authorities in making fuller use of well-established measures, especially inoculation. The figures of deaths from plague in British India during the last five years are as follows:—

Year.	Deaths.	Year.	Deaths.
1924	361,843	1927..	32,160
1925	117,717	1928..	82,078
1926	196,249	Total	790,047

Opium Revenue in British Empire.

Mr. Mander asked the Under Secretary of State for the Colonies what States within the British Empire at the present time were deriving revenue from opium; and to what extent.—Mr. Lunn replied: The following statement shows the British Colonies and Protectorates which derived revenue from the sale of opium in 1928: Hong-Kong, $3,382,101·87. Straits Settlements, $12,322,203. Federated Malay States, $11,782,128. Unfederated Malay States: Johore, $4,224,465; Kedah, $3,053,561; Perlis, $200,608; Kelantan, $435,848; Trengganu, $201,570; and Brunei, $70,447. North Borneo, £98,408; Sarawak, $951,118.00; Ceylon, Rs. 807,000 (estimated receipts 1929–30); and Wei-hai-wei, $2,700 (estimated receipts 1928–29).

MONDAY, NOV. 18TH.

Ex-Service Men and Seven-years' Limit.

Mr. Day asked the Minister of Pensions whether he could now make a statement as to the action the Government proposed taking to abolish the seven-years' limit with regard to ex-Service men. Mr. Shillaker asked a similar question.—Mr. F. O. Roberts replied: The operation of the seven-years' time limit on the making of fresh claims for disablement, and of the arrangements made by the late Government for dealing with certain cases affected by it, has been closely investigated by me since I assumed office. At the present time, more than ten years since the men were demobilised, cases in which disablement by war service can now be justifiably claimed for the first time are, as is admitted on all hands, few in number, and will necessarily become fewer. Old war wounds, thought to have been healed, but now giving trouble for the first time since the war, are readily identifiable, and are already dealt with both by medical treatment and pension. New claims in respect of some ailment or disease are the more numerous, but comparatively very few cases are found on investigation to be genuinely traceable to war service. The situation is one that requires to be met by provision for a small and diminishing number of genuine cases only. These cases require to be dealt with on different lines from those that were suitable at an earlier period of pensions administration.

The Government intend taking such action in regard to the time limit as will secure "that all claims shall still be considered." The arrangements made by the late Government do not, in my opinion, fully secure this object, and therefore the Government have decided to amend and extend them in important respects. For the future, the arrangements for dealing with belated claims for disablement will be such as to ensure the following essential points: firstly, that no application is rejected solely on the ground that it is barred by the time limit; secondly, that every applicant is given explicit opportunity to produce evidence in support of his claim; thirdly, that all evidence in support of a claim is fully considered, and every reasonable line of investigation indicated by the claim is pursued to the full, including medical examination wherever necessary. These arrangements will effectively secure that no bar is raised to the making or consideration of a claim. At the same time, I think it important that ex-Service men should feel assured that their claims are considered impartially. I am, accordingly, with this object, arranging to make use of the statutory powers of the local War Pensions Committees to hear and investigate cases of complaint from dissatisfied applicants. I intend, in addition, to secure the assistance of independent advice by the appointment of medical experts (to be nominated by the Presidents of the Colleges of Physicians and Surgeons), who will be associated with the Department in advising on all cases in which there is material conflict of evidence on the claim.

Replying to a question by Sir A. Pownall, Mr. Roberts said there would be no rejection of claims on the ground of the time limit. Every case would be invited to give evidence; that evidence would be investigated through the War Pensions Committees or through the Ministry, and on top of that they would invite the assistance of independent medical experts.

Sir A. Pownall: Is it not the case that no case was turned down by the late Government? Is it not the case that many hundreds of cases were considered by the late Government, although they had gone beyond the seven-years' limit?

Mr. Roberts said that it was true that numbers of cases had been considered.

Dr. Vernon Davies asked if the right hon. gentleman's reference to medical experts applied to London headquarters alone, or would the Provinces also be included?

Mr. Roberts: They will deal with all cases that are submitted.

Small-pox Concealment at Aden.

Mr. Holford Knight asked the Secretary of State for India whether his attention had been called to the sentence of three months' rigorous imprisonment passed on an Arab, Salem Mohamed Yaseen, at Aden, for concealing cases of small-pox; for what reason the Resident ordered the man's release after he had served five weeks of his sentence; whether he was aware that the objection of the Arabs and others in Aden to the notification of small-pox was due to the fact that the so-called contagious diseases hospital was a collection of huts several miles distant, that patients had to be carried on litters by human beings through the burning sun and with dust blown into mouths and eyes by the hot winds, and that subsequently it was decided that the penalty for breaches of the small-pox order should be a fine not exceeding 50 rupees; and whether he would make inquiries into the case of Salem Mohamed Yaseen, in view of the indignation of a large part of the Moslem community in Aden and district at the treatment he and others received at the hands of the medical officials during the recent small-pox scare at Aden.—Captain Wedgwood Benn replied: I have received communications on this subject from the Anti-Vaccination League, but have no other knowledge of the facts alleged. I have seen, however, a report by the Public Health Commissioner with the Government of India on the outbreak of small-pox at Aden which assumed menacing proportions in March last, and in view of the very serious situation with which the authorities were faced, mainly through *concealment* of cases, I should not feel justified in questioning the measures they found necessary to deal with it.

Sun-bathing by the Serpentine.

Mr. SHAKESPEARE asked the First Commissioner of Works what progress he was making with sun-bathing facilities by the Serpentine.—Mr. LANSBURY replied: I propose to permit mixed bathing in the Serpentine next summer, but I do not at present contemplate making any special arrangements for sun-bathing.

Epizoötic Abortion Among Dairy Cattle.

Brigadier-General CLIFTON BROWN asked the Minister of Agriculture whether, in view of the serious losses suffered by milk farmers from epizoötic abortion, he would issue regulations to make it a notifiable disease; and whether research work was being carried out to find a cure for the prevention of this scourge. Mr. BUXTON replied: Epizoötic abortion differs from the diseases of animals which are scheduled, in that this disease may persist in a herd from three to seven years, or even longer, and, therefore, if it were made notifiable and the movement of animals on to and off of the infected farms controlled, stock-farming would be most difficult, and the cost of administering the order enormous. It is possible by means of a test, which is within the means of all stock-owners, to detect infected animals and protect healthy herds against disease. Research work on this subject is being conducted all over the world, and it is the policy of the Ministry of Agriculture to encourage research workers in this country to concentrate on a cheap means of immunisation.

Cases of Anthrax.

Mr. DUKES asked the Home Secretary the number of cases of anthrax infection reported to his department during the present year, giving the places where the disease was contracted and stating also the number of cases in which infection proved fatal.—Mr. CLYNES replied: The number of cases of anthrax reported during the present year in factories and workshops is 35, three of which were fatal. Cases were reported from Dewsbury, Earlsheaton, Heckmondwicke, Saltaire, Kidderminster, Liverpool, Kilmarnock, Chesham (Bucks), Stockport, Warrington, Runcorn, Bermondsey, Derby, Westbury (Wilts), Worcester, Somerset, and Leeds. In addition, four cases occurred among dock labourers, two of which were fatal. These were reported from Millwall Dock, London Dock, and Alexandra Dock, Liverpool.

Institutional Treatment of Ex-Service Men.

Mr. D. G. SOMERVILLE asked the Minister of Pensions how many disabled ex-Service men were still in institutions under his care; and whether he was satisfied that all possible steps were taken to alleviate the weariness of their protracted convalescence.—Mr. F. O. ROBERTS replied: Apart from cases of insanity in public mental hospitals, there are at present 4774 disabled ex-Service men receiving in-patient treatment at the cost of the Ministry. I am satisfied that everything possible is done to provide both interest and amusement for these cases, so far as the exigencies of treatment admit. Suitable occupation is provided in all cases where this is practicable, having regard to the fact that the majority of the cases in hospital are under treatment for less than six months. Outings and other entertainments are also arranged at all hospitals in coöperation with various voluntary associations.

A NEWCASTLE NURSES' HOME.—Sir Walter Runciman, who recently gave £50,000 to the Royal Victoria Infirmary at Newcastle-on-Tyne, last week laid the foundation-stone of the Runciman Wing of the nurses' home. The building will provide accommodation for 150 more nurses at a cost of about £45,000.

MARRIED WOMEN DOCTORS.—Considerable discussion has arisen in Birmingham in consequence of the intention of the Board of Management of the General Hospital to recommend the governors to declare married women ineligible for appointments on the medical staff, save in exceptional cases. The resolution of the board asks that "women members of the staff who marry during their term of office upon the medical staff be required to relinquish their position in view of the disorganisation of the work of the hospital which may be entailed owing to the demand of their domestic duties."

Medical News.

UNIVERSITY OF CAMBRIDGE.—On Nov. 15th the following degrees were conferred:—

M.D.—R. H. Metcalfe and H. R. Youngman.

M.B. & B.Chir.—G. C. Dewes, T. A. A. Hunter, T. S. Read, and J. L. Newman.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of the Council was held on Nov. 14th, with Lord Moynihan, the President, in the chair.

Diplomas of Membership were granted to 120 of the candidates whose names we gave on Nov. 9th as recipients of the L.R.C.P. (excepting O. S. Kah, E. H. Parkinson, M. E. Roberts, D. Sheehan, P. D. B. Spence, and F. R. Stansfield).

The Licence in Dental Surgery of the College was conferred on the following:—

C. S. Anderson, Richard Bayly, H. M. Bruce-Payne, Hyman Cohen, J. R. Cohen, A. F. De Villiers, W. H. Dodd, W. B. Earsdon, R. H. J. Fairney, W. F. H. Frost, Samuel Gorohovsky, H. L. T. J. Hardwick, F. H. Hughes-Jones, I. J. Immelman, H. G. L. Johnson, R. F. Johnson, W. B. Kilpatrick, E. J. F. King, Oliver Lyth, J. C. McNeill, C. E. Maguire, F. F. V. Manfield, H. H. Markovitch, M. E. Minton, C. A. Palk, W. C. Rae, Eric Schofield, Roy Scoggins, E. C. Shaw, W. H. H. R. Smithurst, R. W. Stevens, A. G. Taylor, W. R. Watts, R. J. Wheatley, A. H. V. Williams, I. C. Wilson, and C. J. Woodcock.

Mr. Victor Bonney was reappointed the representative of the College on the Central Council for District Nursing in London. Mr. V. Bonney and Mr. L. C. Rivett were appointed to give evidence on behalf of the College before the Maternal Mortality Committee appointed by the Ministry of Health.

It was decided to hold an evening reception on Thursday, May 29th, 1930, in connexion with the jubilee celebrations of the British Dental Association.

The President reported that he had received an offer from Mr. Louis Baron of a gift of £500 a year for a period of seven years for a research scholarship in the Royal College of Surgeons, to be called "The Bernhard Baron Scholarship." A resolution expressing gratitude was adopted.

A scheme was approved for granting the scholarships for medical students endowed by the late Mrs. Eliza Macloghlin, and regulations were adopted. The approximate value of each scholarship will be £100 a year.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual dinner was held at the Piccadilly Hotel, London, on Nov. 14th, when Dr. J. J. Buchan, medical officer of health for Bradford, presided, and 100 covers were laid. Proposing the toast of "The Society," in the unavoidable absence of the Minister of Health, Sir Arthur Robinson, First Secretary to the Ministry (grand vizier instead of sultan, as he said), began by recalling what had happened since the Society was founded in 1856; the general health services built up since then were admittedly the first in the world, although it was peculiarly difficult to apply the principles of local government to a community like London which was as large as half a dozen nations. The lamented death of Sir John Gatti had delayed the issue of the report which would grapple with this situation. Especially on problems of nutrition had research made progress, but practice lagged far behind, and the Ministry had been called on to lend a hand. The Local Government Act of 1929 was now in being; since 1875 there had been nothing but piecemeal legislation, but the new Act remodelled every department of local government. The primary thing in it was that by next April the new authorities must make efficient arrangements to take over the work of the poor-law guardians who had been at their job for a hundred years. The Ministry had been criticised for not breaking up the poor-law at once, but the right way to set to work, said Sir Arthur, was not per saltum, but gradually, quietly, and in the end surely. Under the Act the control of the health services by the Ministry passed away. Comprehensive surveys of public health would be made in the areas (this was essential in view of the provision in the Act to reduce grants in case of default), and the whole of this information would be at the disposal of local authorities and their medical officers, the Ministry issuing periodic papers to sum up the results of their inquiry. This, he said, was the function of a central health department; not, as had been put to them, to issue "plain rules for plain people," but to ascertain facts, and leave voluntary societies and local authorities to popularise them. Under the Act there would be a resurvey of country areas, for until the areas were sound the functions of local government could not be properly distributed. The medical officer to the local authority must needs be an administrator, for he had to link up his work with the rest of the municipal work; he had to frame a general policy in which health should play a leading part. The health authority was now put in charge of the whole of the health functions; time would show the vast importance of this step in its effect on administration and research. The institutional provision to be taken over from the guardians was variable in standard, from the type of the old poor-law infirmary to that of the first-rate hospital; in the hands of the local authority there would be a gradual tendency upward. This, it had been said, would be a threat to the voluntary hospitals; but take the example of Bradford where, in spite of the existence of the municipal hospital, the voluntary hospital was putting through an important scheme of extension. Medical officers must realise that they could learn a great deal from the voluntary hospitals; it was up to them to see that full use was made of them, so that there should be ample accommodation available in all areas. Until, said Sir Arthur, you got constant consultation between the local authority, the medical officer of health, and the voluntary hospitals, you would never get efficiency. Touching on the question of whole-time service, at the head there must of course be a whole-time administrator; how the principle worked out in the lower grades he would watch with interest. In conclusion, he announced the intention of the Minister of Health to introduce at an early date a Bill which would provide for the superannuation of all local government officers. Dr. Buchan, in responding, said the Society had the most earnest intention of carrying out the great work which had been initiated by the Ministry of Health; they appreciated fully the need for unification of the health services and for the unification of hospital work. His Society had already taken a large part in getting health maxims over to the people, but local differences made this harder in some places than in others. Prof. J. Johnstone Jervis, president of the Yorkshire Branch, proposing "The Guests," pictured with great humour the distressful situation of each body represented and their need for succour at the hands of his own Society. Fourfold response to this toast was made by the Bishop of Sodor and Man, Sir John Rose Bradford, Sir Robert Bolam, and Mr. J. H. Palin, M.P. Sir Robert remarked that medical officers of health had in the Local Government Act an unparalleled opportunity so to alter the minds of legislators as to make the work of the medical profession at large bear fruit. The toast of "The President," proposed by Alderman H. Thornton Pullan, J.P., chairman of the Bradford Health Committee, was accorded musical honours, and after responding Dr. Buchan called on Dr. R. A. Lyster to propose the toast of Mr. G. S. Elliston, Executive Secretary of the Society, who would be resigning that post next September after 11 years' service. In his reply Mr. Elliston made it clear that his retirement from secretarial work was only a prelude to greater activity as a journalist in public health. During the evening Mr. Norman Williams delighted the company with his mellow voice.

ABERDEEN UNIVERSITY CLUB, LONDON. — The eighty-second half-yearly dinner of this club will be held at the Trocadero Restaurant on Thursday, Nov. 28th, under the chairmanship of Dr. T. Wardrop Griffith. The Secretary's address is 9, Addison-gardens, W. 14.

NO. 14 STATIONARY HOSPITAL.—The tenth annual dinner of the medical officers of this hospital will be held at the Trocadero Restaurant, Piccadilly-circus, London, W., on Friday, Dec. 6th. Colonel C. R. Evans will be in the chair. Members of the mess who have not received notice are asked to apply to the Secretary, Dr. H. L. Tidy, 39, Devonshire-place, W. 1.

BRITISH SERBIAN UNITS.—The annual reunion dinner of the British Serbian Units Branch of the British Legion and of all friends of Serbia will be held at the Grafton Hotel, Tottenham Court-road, London, W., on Saturday, Nov. 30th, at 7.15 P.M. Mr. Philip Mitchiner, F.R.C.S., will take the chair. Tickets may be had from Miss C. M. Marx, 24, Melcombe-court, Dorset-square, N.W. 1.

THE BRITISH INSTITUTE OF RADIOLOGY.—The annual conference of the British Institute of Radiology, with the accompanying exhibition, will be opened on Wednesday, December 4th, at the Central Hall, Westminster, by Mr. Arthur Greenwood, the Minister of Health. On Friday, December 6th, the annual dinner of the Institute will be held in the Trocadero Restaurant, Piccadilly, at 7.30 for 7.45 P.M.

DISEASE IN THE TROPICS.—Sir Leslie Wilson, late Governor of Bombay, will speak on the Hospital for Tropical Diseases in London and its Work for the Empire at a meeting at Mrs. F. S. Franklin's house, 44, Lancaster-gate, London, W., at 5 P.M., on Thursday, Nov. 28th. Admission is by invitation cards only, and they may be had from the resident Secretary of the Hospital for Tropical Diseases, Endsleigh-gardens, W.C. 1.

THE IVORY CROSS.—The fifteenth anniversary dinner of this Society will be held on Tuesday next, November 26th, at the Hyde Park Hotel, when the Duke of York will preside.

MERSEYSIDE HOSPITAL COUNCIL.—The report of the first year's working of the Merseyside Hospital Council states that there are already over 210,000 workmen employed in about 8000 business undertakings who are contributing an average of 7*s.* 6*d.* a year to the fund. Employers add one-third to their employees' contributions.

WILLIAM MACKENZIE MEDAL.—This medal "for original work in ophthalmology of outstanding merit," which has been awarded this year to Mr. W. S. Duke-Elder, is to be presented to him at the Glasgow Eye Infirmary at 8 P.M. on Monday, Dec. 2nd, when he will deliver an address on the Clinical Applications of the Newer Conceptions in the Physiology of the Eye.

BIRMINGHAM CHILDREN'S HOSPITAL.—Extensions to this institution opened last week increase the total accommodation to 230 beds. They comprise an isolation block, a new private ward for fee-paying cases, a medical ward, and extra facilities in the out-patients' department. The cost has been £25,000, and a babies' ward and a nurses' home have yet to be added. In the last 12 years the hospital has cost £160,000.

CREMATION IN MANCHESTER.—The number of cremations in Manchester has risen from 265 in 1925 to 436 in the 12 months ending with August. Since the crematorium opened the total number has been 5700. The national statistics of cremation also show an advance, the number for the 12 months ended on June 30th being 4105 as against 3260 in the preceding year. The total number recorded up to date is 40,609. There are now 18 crematoriums in this country, and another at Edinburgh has just been completed.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Nov. 25th.—8 P.M., ODONTOLOGY. Paper: Mr. J. H. Badcock: The Design of Partial Dentures Considered in Relation to the Health of the Oral Tissues. Casual Communications:—Mr. F. St. J. Steadman: A Dentigerous Cyst in Connexion with a Supernumerary Incisor. Dr. E. W. Fish: A Report on Dr. Gottlieb's Histological Study of the Results of Traumatic Occlusion.

TUESDAY.—5 P.M., MEDICINE. Clinical Meeting at the London Hospital, E.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. The Improvement in the Public Milk-supply—Is Pasteurisation Necessary? Speakers: Mr. J. Monton and Mr. H. W. Steele-Bodger. Discussion: To be opened by Dr. R. Stenhouse Williams, followed by Dr. J. F. Halls Dally.

THURSDAY.—8.30 P.M., UROLOGY. Pathological Evening.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Nov. 25th.—8 P.M., Clinical Evening.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Nov. 28th.—8.30 P.M., Mr. F. Llewellyn Jones, M.P.: The League of Nations and the International Control of Dangerous Drugs. To be followed by a discussion.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, Nov. 29th.—8.30 P.M., General Meeting. Papers will be read by Dr. N. L. Lloyd and Mr. V. E. Lloyd on Observations on the Urinary Excretion of Novarsenobillon in Syphilis and its Relation to Toxic Effects. A discussion will follow.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, Nov. 25th, to SATURDAY, Nov. 30th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Lecture by Mr. T. G. Stevens: Prolapse. No fee.—Tues., 8.30 P.M., Two lectures, especially suitable for M.R.C.P. candidates:—Dr. Kinnier Wilson: Encephalitis; Varieties; Relation to Fevers and Exanthems. Fri., 8.30 P.M., Dr. Kinnier Wilson: Disorders of Movement; Classifications; Pathogenesis.—VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W. Mon., 10 A.M., Demonstration by Mr. Denham Pinnock. No fee.—HAMPSTEAD GENERAL

Hospital, Haverstock Hill, N.W. Thurs., 4.30 P.M. Demonstration on Spinal Manipulation by Dr. T. Marlin. No fee.—Royal National Orthopædic Hospital, 234, Great Portland-street, W. Second week of special course. All day.—St. Mark's Hospital, City-road, E.C. All day course in Proctology.—Further information from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

Monday, Nov. 25th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Wards.

Tuesday.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw, Medical Out-patients. 2.30 P.M., Sir Henry Simson: Gynæcological Operations.

Wednesday.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. Dr. Scott Pinchin: Medical Out-patients.

Thursday.—11.30 A.M., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

Friday.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Shaw: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.

Saturday.—9 A.M., Mr. Vlasto: Throat, Nose and Ear Operations. 9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Children's Department.

Daily, 10 A.M. to 5 P.M., Medical, Surgical and Special Out-patients, Operations, Ward Visits, Anæsthetic Courses.

SOUTH-WEST LONDON POST-GRADUATE SOCIETY, St. James's Hospital, Ouseley-road, Balham, S.W.

Wednesday, Nov. 27th.—4 P.M., Mr. Maurice Whiting: The Ophthalmoscope in General Practice.

NORTH-EAST LONDON POST-GRADUATE COLLEGE. Prince of Wales's General Hospital, Tottenham, N.

Monday, Nov. 25th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

Tuesday.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

Wednesday.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

Thursday.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics. Operations.

Friday.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations. 4.30 P.M.: Demonstration on Practical Neurology by Dr. L. R. Yealland.

NATIONAL HOSPITAL, Queen-square.

Monday, Nov. 25th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. James Collier: Muscular Atrophies.

Tuesday.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Mr. Armour: Surgery of Compression Paraplegia.

Thursday.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Walshe: Vascular Lesions of Nervous System.

Friday.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: Clinical lecture.

UNIVERSITY COLLEGE, Gower-street, W.C.

Monday, Nov. 25th.—2 P.M., Prof. Herbert Spencer: Medicine in the Days of Shakespeare. (Public Lecture.)

ST. PAUL'S HOSPITAL, Endell-street, W.C.

Wednesday, Nov. 27th.—4.30 P.M., Mr. Frank Kidd: Radium for Malignant Disease of the Bladder.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Monday, Nov. 25th.—5 P.M., Mr. J. C. Dawes, M.I. Mech.E.: Disposal of Refuse.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road.

Friday, Nov. 29th.—4 P.M., Mr. C. Gill Carey: Diagnosis of Sinusitis.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.

Thursday, Nov. 28th.—9 P.M., Dr. J. L. Livingstone: *Some Points in the Treatment of Phthisis.*

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

Tuesday, Nov. 26th.—3.15 P.M., Mr. G. G. Penman: Diseases of the Eye in Childhood.

PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, W.

Friday, Nov. 29th.—6 P.M. (at the Medical Society of London, 11, Chandos-street, W.), Dr. R. G. Gordon: What is the State Doing for the Individual and the Race, and How Much Efforts may be Amplified.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

Wednesday, Nov. 27th.—4 P.M., Prof. S. L. Cummins: Some Aspects of the Tuberculosis Problem.

ANCOATS HOSPITAL, Mill-street, Manchester.

Thursday, Nov. 28th.—4.15 P.M., Dr. G. E. Birkett: General Principles of Radium Therapy.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

Friday, Nov. 29th.—3.30 P.M., Mr. Townrow: The Treatment of Acute and Subacute Media.

ST. MARY'S HOSPITALS, Whitworth-street, Manchester.

Wednesday, Nov. 27th.—4.15 P.M., Mr. Comyns Berkeley: The Teaching of Midwifery. (Lloyd Roberts Lecture.)

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, Nov. 26th.—4.15 P.M., Mr. J. Morley: Hydronephrosis.

Friday.—4.15 P.M., Dr. H. Dove Cormac: Border-line Cases: the Physical Basis of Mental Disorder.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

Wednesday, Nov. 27th.—4.15 P.M. (in the Royal Maternity and Women's Hospital), Dr. A. N. McLellan: Demonstration of Obstetrical Cases.

Appointments.

Bainbridge, W., M.B., Ch.B. Edin., D.P.H., has been appointed Honorary Ophthalmic Surgeon to the Hull Royal Infirmary.

Claye, A.M., M.D. Leeds, F.R.C.S. Eng., Honorary Assistant Surgeon to the Hospital for Women at Leeds.

Gill, J. W., M.B., Ch.B. Aberd., Certifying Surgeon under the Factory and Workshop Acts for the Montrose District of the County of Angus.

Randle, A., M.D. Lond., Medical Superintendent of the Mile End Hospital.

Vacancies.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Swindon (Wilts.) and Berkhamsted (Herts).

Births, Marriages, and Deaths.

BIRTHS.

Davidson.—On Nov. 8th, at Square House, Christchurch, Hants, the wife of Dr. A. Whyte Davidson, of a daughter.

Earp.—On Oct. 30th, at the Presbyterian Hospital, Denver, Colorado, U.S.A., the wife of Dr. J. Roslyn Earp, of a son.

Gabb.—On Nov. 16th, at Copthorne, Guildford, the wife of Dr. Harold Gabb, M.C., of a daughter.

Patterson.—On Nov. 16th, at Plas-yn-dre, Ruthin, the wife of S. W. Patterson, M.D., of a daughter.

Roffey.—On Nov. 10th, in London, the wife of Dr. Bernard W. Roffey, of Gillingham, Kent, of a daughter.

MARRIAGES.

Brown—Cory.—On Nov. 9th, at Christ Church, Montreux, Surgeon-Commander Robin Brown, Royal Navy, to Dorothea Grace Cory.

Tom—Eadie.—On Nov. 11th, at Northleach Parish Church, Dr. Arthur Tom, of Bellevue House, Cheltenham, to Marjorie, daughter of Mr. and Mrs. H. G. Eadie, Charlton Park Gate, Cheltenham.

DEATHS.

Clarke.—On Nov. 10th, at "Netherleigh," Thorne-road, Doncaster (very suddenly), Henry Joy Clarke, M.D., J.P., aged 72.

Falkiner.—On Oct. 30th, at Dublin, Ninial McIntire Falkiner, M.D., F.R.C.P.I., late of Tyrone.

Forbes.—On Nov. 14th, at Sierre, Switzerland, Dorothea Christine Forbes, M.R.C.S., L.R.C.P., D.P.H., younger daughter of the late George Forbes, M.D., Blackpool, aged 32.

Hackett-Wilkins.—On Nov. 15th, at Mongeham Lodge, Great Mongeham (near Deal), Colonel Thomas James Hackett-Wilkins, O.B.E., I.M.S. (retired).

Melland.—On Nov. 14th, after a brief illness, Brian Melland, M.D., of The Bower, Ashley-road, Altrincham, in his 66th year.

Openshaw.—On Nov. 17th, at a nursing home, after a few weeks' illness, Thomas Horrocks Openshaw, C.B., C.M.G., F.R.C.S., of Wimpole-street, W., aged 73.

Reid.—On Nov. 18th, at Southsea, Sir Archdall O'Brien Reid, K.B.E., M.D., F.R.S.E., aged 69.

Shaw.—On Nov. 11th, at London-road, St. Leonards-on-Sea, Frank Herbert Shaw, M.R.C.S., F.R.C.P.

Shove.—On Nov. 16th, at Upper Richmond-road, Putney, S.W., Edith Shove, M.B., aged 81.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE MANAGEMENT OF PATIENTS SUFFERING FROM CANCER OF THE BREAST.*

By F. Hernaman-Johnson, M.D. Aberd., D.M.R.E.,
RADIOLOGIST TO THE FRENCH HOSPITAL, LONDON; PHYSICIAN IN CHARGE, X RAY AND ACTINOTHERAPEUTIC DEPARTMENT, CROYDON GENERAL HOSPITAL.

The management of patients suffering from cancer of the breast begins in the general practitioner's consulting-room. Every patient who consults her doctor because of trouble in her breast is a possible subject of cancer. The first duty of the doctor is to differentiate, where possible, between the real and the imaginary—between that which has an existence in the external world and that which has its being only in the mind of the patient. Cancer-phobia is a complaint calling for sympathy and tactful handling; otherwise, the mental state of its victim may be worse than that of the patient suffering from the disease itself. A witty friend of mine, asked if cancer was a curable disease, replied: "Of course it is; I have been cured of it myself hundreds of times!" Indeed, there are few of us who have reached middle age who have not been cured of it at least once or twice. For cancer-phobia is an almost universal complaint, though fortunately in most cases the attacks are infrequent and fleeting.

When a patient presents herself complaining of vague pains in the breast and nothing whatever can be found on physical examination, she should be questioned carefully about trauma. If nothing definite can be elicited, it is justifiable to ask her point blank what she fears and why. Generally it will be found that she has recently been in contact with some friend or relative who has cancer, or has been reading literature on the subject. Such patients require the most vigorous reassurance. It should be explained to them that pain is not an early sign of cancer. But it must be remembered that the patient has felt pain—or if one likes to go into fine-spun distinctions—believes that she has felt pain—and requires an explanation. The blessed word "neuralgia," talk about being "run down," and the prescription of a tonic are usually all that is required to make her happy. The doctor should never let her get the idea that he thinks her fussy. Some day she may have real trouble in her breast and nothing should be done which would make her hesitate to consult him a second time.

Even when the breast is absolutely normal to palpation, there are two things which should suggest that an eye should be kept on the patient. If there is a definite history of injury, even years before, caution is necessary; and when there is a pronounced family history of cancer the chances of an individual member developing it are greatly increased.

Next comes the patient with the suggestion of a vague "fullness," scarcely to be called a "mass," somewhere in the breast. If there is tenderness, it is permissible to regard this provisionally as mastitis. Many such cases yield to X rays in small doses, and no more is heard of the trouble. But if any signs or symptoms persist after a few weeks of treatment diagnosis becomes urgent. There is only one certain means, and that is the surgical removal of a section for microscopic examination. To be really effective, and more especially to establish a negative diagnosis, this must be done at leisure; a frozen section at the time of operation is not enough. This again means an interval of days, and some surgeons—notably those of the New York Memorial Hospital—are insistent that such an interval is dangerous, as the exploratory section leads to dissemination. Their view is perhaps extreme, but I am myself terribly frightened of disturbing a malignant growth by surgical trauma, however slight, as I have seen tragedies follow. All risk from the incision can, however, be avoided by using a recently introduced form of diathermic knife which seals the tissues as it passes through them but with a layer of coagulation so thin that healing by first intention is not interfered with. If the incision is large enough to require stitching there is again an element of risk. It should not be difficult to devise a diathermic needle which could sterilise its own track before the suture is pulled through. When such technique is not available, X rays should be administered both before the exploration and in the interval between this and total removal, should it prove necessary.

If a single well-defined lump is felt, no matter how small, it should be remembered that statistics tell us that the chances are at least two to one that it is cancer. It may, of

anxiety. They almost always disappear under X rays or radium. *Large nodules sometimes prove refractory* and require surgical removal, but it is probable that a freer use of radium would, even in such cases, render operation very seldom necessary. For widespread simultaneous invasion of the skin, with a tendency to ulceration, we must resort to X rays combined with light. This, the most distressing form of recurrence, will often prove largely intractable—but at the worst it is generally possible to keep the patient from becoming the mass of stinking sores which would formerly have been her fate. Radiation, while it may not cure, does have an inhibiting effect upon putrefaction even in the worst cases.

The patient with inoperable recurrence in the cervical glands may present a serious problem, as they are apt to cause great pain. Such patients are often very low in vitality and spirits, and respond poorly, or even adversely, to X ray treatment. I have found from experience that the best thing to do is to put them on a course of ultra-violet light. This usually has a remarkable effect upon their health, weight, and spirits, and enables them to profit by deep X rays to the glands at a later date. There is no doubt in my mind that in some instances patients of this type may be literally snatched back from the edge of the grave by treatment with ultra-violet light. Nor is the effect merely evanescent. It may, to my personal knowledge, prolong life for two years or more. This experience is also that of workers in the light and X ray departments of the Cancer Hospital.

I have known deep X rays in large doses relieve the swollen arm due to axillary recurrences. In its worst form it is a dreadful affliction. Amputation of the fore-quarter has been proposed for it and once or twice carried out. It is admittedly a desperate remedy, but in a really bad case in a relative of my own I feel sure that I should have it carried out if I could find a surgeon to do it. Internal metastases—in the lungs, mediastinum, or liver—defy radiation, but whenever there is pain it should be tried for its sedative effect. Metastasis in bone is a field in which deep or high-voltage therapy gives results which cannot be obtained by less penetrating rays. It is frequently possible to cause the regression of a particular growth of bone, though of course multiple metastases will conquer in the end. Metastatic deposits in the spine frequently cause severe and intractable pain. Deep X rays may relieve this to some extent, but the difficulty is that patients so affected are usually too ill to be brought for X ray treatment.

The Hopeless Case.

As the story of the cancer patient begins with the general practitioner who makes the diagnosis so, as a rule, it ends with him in sole attendance. But his final task, painful though it often is, has been immensely lightened by the aid of the radiologist. When I was in general practice I was seldom without at least one patient dying of cancer. The reason was not the abnormal size of my practice but the length of time these unfortunate patients took to die. Often the whole house was permeated with the smell of them and the odour seemed positively to rush out into the street at once when the front door was opened. Yet they lived for months, a terrible burden to themselves, their families, and their medical attendants. One of the greatest contributions of radiotherapy to medicine has been that such patients are now for the most part kept on their feet, physically unobjectionable, until within a few weeks of the end. Still, *there does inevitably come a time when the patient can* no longer struggle out to attend for X ray treatment. It is wise to forestall this time when one sees it approaching by suggesting a rest. This course is far sounder from a psychological point of view than to wait until the patient herself feels that she can no longer make the effort. To allow her to come to this point is, as a rule, to make her abandon hope, whereas to hold out the prospect of a later return for treatment avoids any abrupt realisation.

When the patient is finally bedridden morphia should certainly not be withheld, but it may be desirable at first to give it by the mouth only and to camouflage it as a tonic. Sometimes heroin causes less general disturbance. I think it is cruel to force highly concentrated nourishment upon these patients against their will, or, at any rate, in the absence of any desire. Under such circumstances the only thing the patient really craves is a little water; this is no doubt nature's way of hastening dissolution.

One drug should certainly be avoided for patients in extremis, even those who, while they have not actually reached this stage, are obviously not far from it. That drug is lead. I say this not because I think that lead has no effect in inhibiting the growth of cancer. Sometimes it has such an effect, and that is why in the moribund case it may delay the final exit. But the risk is, in my experience, that, while life is prolonged, pain is increased. I can express no opinion as to the general value of lead in cancer, but if it is tried at all let it be on those whose general health is good, so that the drug may work in conjunction with the *patient's power of resistance. That the body offers a* resistance to the spread of cancer can scarcely be doubted, and that the resistance may suddenly give way is a matter of clinical observation. Salvarsan and quinine, both at first thought to be specific remedies acting directly on the respective organisms of syphilis and malaria, have been shown to require the coöperation of the body cells in order to effect their purpose. We may be sure that any beneficial action of lead must presuppose reactive power in the system, and its ultimate success cannot be looked for when there is already extreme exhaustion.

General Care.

This is a matter which almost exclusively concerns the family doctor. Is the patient to be told the nature of her complaint? Some years ago it was customary in most cases to conceal the truth; whereas in men suffering from malignant disease, frankness has always been the rule rather than the exception. But times have changed; women have taken their place beside men in almost all the business of life, and there would seem to be no further justification for withholding disturbing knowledge simply because of the patient's sex. Some women would go utterly to pieces if they knew they had cancer, but so would some men. Each case must be judged on its merits. In most instances it is desirable that the patient should know what is the matter. How else can we secure her intelligent coöperation in her after-treatment? It is, fortunately, not necessary that the word cancer should even be mentioned. It is possible to establish a perfect understanding between doctor and patient without any definite statement. When a complete removal of the breast is recommended, most women know, or at least strongly suspect, what this means. *It is a mistake* to give any patient an opening to ask forthwith "is it cancer?" The advice as to operative removal should be coupled with a statement that it will be necessary for some time afterwards to employ X rays at intervals, in order to avoid any risk of return. This suggestion of the possibility of recurrence is in nine times out of ten sufficient to stop the patient from asking a direct question; at the same time, she is comforted by the thought that something will be done to forestall what she dreads. A question as to whether X rays will make certain that there will be no further trouble is not often asked. If it is, I think the practitioner is justified in being very reassuring. At the worst there is one chance in three that she will be alive and well in three years' time, and with proper post-operative treatment my belief is that the odds against survival are reduced to 60 per cent. This is the scientific *forecast* based on *statistics, but the general* practitioner is dealing with an individual, and the mental attitude of that individual to her trouble is going to have an effect upon the survival prospects in her particular case. Recurrence in cancer depends not only upon the malignancy of the growth but upon the patient's resistance to it. It matters little what view we take of the essential nature of neoplasms—whether we regard them as analogous to the manifestation of syphilis or tubercle—or look upon them as collections of atavistic cells which have revolted from civilised restraint and determined to indulge in a primeval orgy of reproduction. In either case the tumour cells do not have it all their own way. Pathology tells us that local barriers of fibrous tissue are set up, and clinical observation makes it abundantly clear that general resistance may suddenly fail, with dramatic consequences. A patient who *has been going along, perhaps for years, without much change,* fails to appear at the clinic. The next day a letter arrives from a relative to say that "Mrs. So-and-So seems to have gone all to pieces in the last week," and in a few days she may be dead. Sometimes, if there is a little warning, the resistance may be restored for a time by purely constitutional means, such as treatment of the whole body by light. Or the re-energising process may be a purely mental one—as when a patient hears that a much-thought of son or daughter is travelling half across the world to see her. Under such circumstances I have seen patients revive in a most extraordinary way, and sometimes survive for months, or even a year or two, when it had seemed to all that the end was approaching. The converse of this is also seen: a patient doing well receives a shock, or undergoes a period of some anxiety, and breakdown occurs. The importance of mental attitude must therefore be fully recognised, and it is not only justifiable but obligatory upon us, while admitting by implication the nature of the disease, to take an optimistic view of the prospect of cure.

Fifty years ago to tell a patient that he had consumption was regarded as a death sentence. Only yesterday I had in my consulting room a man, 60 years of age, who told me that when in his twenties he had had, while out shooting, a sudden attack of pulmonary hæmorrhage. Two of his brothers had died of consumption, and he immediately contemplated using his gun on himself. On second thoughts, however, he decided that it would cause less disturbance if he merely ran full speed up a neighbouring hill. This he did, firmly believing that this violence would produce a fatal rupture; he arrived panting at the top, but the expected flood did not come. It was just at the beginning of the fresh-air cure era. The young man looked around, saw that the prospect was fair, and decided to build himself a hut on the hill top. He did so, lived in it for a year, and has never shown any signs of the disease since. The mention of lung tubercle does not now produce a feeling of despair, though many still die from it. Instead of side-stepping the issue with cancer patients, it would be far better to try to strip the disease of the worst of its terrors. Judged by relative standards, cancer is not among the worst of maladies. Under modern conditions, it is, as a rule, comparatively merciful. Rheumatoid arthritis in its worst forms, tuberculosis, actinomycosis, osteomyelitis, and chronic progressive disease of the nervous system may all be far worse afflictions, yet their names do not inspire the same dread. Many, even in the medical profession itself, are inclined to indulge in a kind of devil-worship, shaking their heads and chanting the words "the cause will never be discovered, and there is no cure," as if they were an invocation. Let us turn our backs on superstition. So long as there is no visible recurrence, the purely precautionary nature of X rays or other treatment should be emphasised. If recurrence actually occurs, it should be made light of and its purely local nature insisted on. If small recurrences are dealt with effectively by radiation, it is astounding to see how little the patient comes to fear them. Faith in the treatment, once established, is fortunately hard to shake. But if misfortune decrees that intractable external lesions become established before internal ones have had time to do their work, the process is usually so prolonged that patients have time to accustom themselves to the idea that they will never be really cured, and for the most part do not trouble the doctor with embarrassing questions. If they do ask, it is no use promising a cure for what is obviously getting worse in spite of treatment.

It is generally admitted that nearly all patients who have had cancer of the breast will show a recurrence if they live long enough. I have myself seen this happen after more than 20 years of freedom. Unless we are to regard such manifestation as cancer de novo, we must assume that malignant cells can lie dormant literally for decades. This means that every patient should be regarded as holding metastases at bay by reason of her natural powers of resistance. Therefore all the recognised means of maintaining good general health should be employed—fresh air, food containing a due supply of vitamins, suitable clothing, exercise, and rest and change when necessary. One must avoid making such patients think they are invalids, but tasks involving excessive strain or worry should not be deliberately entered upon.

Eight Points.

(1) Indefinite resistance or fullness which is not tender calls for exploratory section.

(2) Such exploration is dangerous unless performed with a special diathermy knife, or else preceded and followed by X rays.

(3) Mastitis showing a typical clinical picture may be treated for some weeks by X rays, to see if it subsides.

(4) In the majority of cases, the patient finds a nodule by accident while washing. Of such cases treated by surgery alone, two out of three will be dead in three years, certainly in five.

(5) Pre- and post-operative X rays and light treatment greatly reduce the percentage of external recurrences, and in many instances prolong life.

(6) Operation plus X rays is at present the treatment of choice, but it is possible that in the near future radium will oust surgery as routine treatment.

(7) Trauma is of great importance in the ætiology of breast cancer. Physiotherapeutic treatment at an early stage will reduce the risk of subsequent malignant change.

(8) The successful treatment of patients suffering from carcinoma mammæ is largely concerned with maintaining their resistance to latent foci of the disease. In maintaining the resistance, mental health is as essential as that of the body.

PUBLIC HEALTH IN GIBRALTAR.

ACCORDING to the annual general report for 1928, now issued from the Colonial Office, the estimated total population of Gibraltar at the close of the year was 16,281, of whom 15,719 are fixed residents. These figures represent the population between sunset and sunrise, but some 4500 aliens and 1500 British subjects resident in the neighbouring Spanish town of La Linea come into Gibraltar daily. The number of births during the year was 366, of which 212 were boys and 154 girls. The birth-rate per 1000 was 23·28. The births refer to the fixed population only, as under the Aliens Order in Council no alien may give birth in the Colony. 293 deaths were registered, and the crude death-rate was 17·40 per 1000. Infantile mortality was 122·0 per 1000. Deaths from pulmonary tuberculosis were 1·0 per 1000; 21 persons died from cancer. The general health of Gibraltar continued to be good. The vital statistics are considered satisfactory, and with regard to infectious disease there is nothing of outstanding importance to record, except an outbreak of measles, of which 961 cases were reported, 11 being fatal. The epidemic was of a mild nature, and complications were rare. The sanitary work of the Colony is carried out by the city council, who also have charge of the roads, lighting, water-supply, and hygienic measures in dwellings. A new Ordinance has been enacted to bring local legislation up to the standard required by the International Convention relating to Dangerous Drugs.

The general climate of Gibraltar is mild and temperate, though somewhat hot and oppressive during the months of July and August. The meteorological record for 1928 shows 69·5° F. as the mean maximum temperature, the highest shade temperature being 90·0° F. on July 27th, and the lowest 42° F. on Jan. 1st. The rainy season is spread over the period from September to May; the annual average rainfall is 35 inches, but in 1928 only 25·44 inches were registered, of which 7·06 inches fell in November.

The tourist traffic again showed a slight increase. Various improvements are being carried out which will make it possible for tourists to visit the three principal sights of Gibraltar—the Galleries, the Water Works, and the Moorish Castle—in greater comfort and in shorter time than has hitherto been required. It is also hoped that a first-class hotel will be erected in the near future.

AN AMERICAN INVESTIGATION OF CONTRACEPTION.

THE Holland Rantos Company, dealers in obstetrical and gynæcological materials, 150, Fifth-avenue, New York City, has made a statistical investigation of the efficacy of the contraceptive technique, which it recommends. This consists of the routine combination of an occlusive device, a spermaticide, and a douche. The Rantos type of occlusive pessary resembles the familiar Mensinga type, except that the Rantos has a spiral spring in the rim in the place of the watchspring which maintains the shape of the Mensinga. The spermaticide is a lactic acid-jelly combination, with the trade-name of Koromex. It is put up in a collapsible tube, to the screw nozzle of which a cannula is attachable. The jelly is smeared round the rim of the pessary, and is expressed upon the rubber dome of the pessary, which is worn convexity upwards, from the collapsible tube. The pessary requires to be fitted by a doctor. The Company sent out 2300 questionaires, and received 726 replies. These showed that the combined method of diaphragm and spermaticide gave a satisfactory result in 90 per cent. of all cases. In the hands of specialists in contraception, the percentage of success is claimed to be as high as 97 or 98 per cent. Satisfactory results were recorded with the spermaticide alone in 66·8 per cent. of cases.

RICKMAN'S SECOND SERIES OF EIGHTEENTH CENTURY POPULATION FIGURES.

Two years ago we noticed a book by Mr. G. Talbot Griffiths entitled "Population Problems of the Age of Malthus." Since this date there has come to light in the General Register Office a bound volume of manuscript notes and workings from which the estimates for the pre-census populations were derived. Some of the implications of these notes are discussed in a paper by Mr. Griffiths that has appeared in the *Journal of the Statistical Society* (Vol. XCII., Part 2, 1929). They have an important bearing upon the comparative reliability of Rickman's first and second series of calculations of the pre-census population of England and Wales, appearing respectively in 1801 and in 1841. It has generally been assumed that of these two series the later was the more reliable. Mr. Griffiths's chief aim in his paper is to show that, in fact, the data from which the 1801 series was calculated were more reliable than those that formed the basis of the 1841 series.

ANOTHER LOCAL ANÆSTHETIC.

WE published last week a note under this heading which referred to a drug shortly to be placed on the market by the Clayton Aniline Company, Limited, under the name of Percain. A further reference to it will be found in our Vienna letter this week. The company informs us that the drug is being tried in certain metropolitan hospitals and privately, and can be obtained from their pharmaceutical department at 40, Southwark-street, London, S.E.

QUEEN ALEXANDRA MILITARY HOSPITAL, MILLBANK. The Prince of Wales will open the new wing of this hospital on Nov. 26th at 12 noon. Application for tickets should be made to the Commanding Officer of the hospital.

An Address

ON

PSYCHOLOGY AND MEDICINE.

Given to the Medical Section of the British Psychological Society on Oct. 23rd, 1929,

BY HENRY YELLOWLEES, M.D. GLASG.,
F.R.C.P. EDIN., D.P.M.,
PHYSICIAN AND LECTURER IN PSYCHOLOGICAL MEDICINE TO ST. THOMAS'S HOSPITAL.

IN the closing pages of his text-book William James stated that Psychology was not a science; that it was only the hope of a science, and that it was waiting for some one who would be to it what Lavoisier was to chemistry, and what Galileo was to physics. He added that when such a person arose the necessities of the case would make him a metaphysicist. Such a person has now arisen, and the revolution which James foresaw has taken place. Few will deny that Freud has been to psychology all that Darwin was to biology and that Newton was to mathematics, and more. That is my personal view, and I hold it sincerely. The necessities of the case, however, have not succeeded in making Freud a metaphysicist, though they have gone some distance towards accomplishing that feat with Jung. Apart from this one point James's prophecy has been wonderfully fulfilled.

PSYCHOLOGY AND SCIENCE.

Freud has lifted from psychology for ever the reproach of being only the hope of a science. In spite of the stupendous difficulties in the way of collecting data, and of the unusual and elusive nature of the data when found, he has triumphantly brought order out of chaos by applying the methods and the spirit of science to the deepest and most secret workings of the mind. We may ignore the debatable fringe which is inevitable in every great scientific advance, and is merely the crest of foam which the wave may carry along with it or may leave behind. The fact remains that he has reduced psychology to a system of tested and proven theories which can be applied with helpful and illuminating result to practically every department of human activity.

It is not unfair to say that this system claims to be the only system of truly scientific and practical psychology. It certainly realises and states that it is incompatible with any other. I propose therefore to deal almost entirely with it in what I have to say. I have called this paper Psychology and Medicine, but you will understand that when I use the word "psychology" it is the doctrines, the methods, and the view-point of psycho-analysis that I have in mind. It is with the application of scientific psychology to medicine that we are now concerned, and we may look for a moment in passing at the question: Who is to do the applying?

I need not remind you that new scientific knowledge, once given to the world, becomes the common property of all interested and intelligent people. A very short course of instruction will enable any average student to know more about antisepsis than Lister, and more about political economy than Adam Smith. Each generation begins where its predecessors left off, and the discoveries of a great mind, once added to the stock of human knowledge, become the current coin and the commonplaces of lesser minds who would never have had the genius to make them, and may not have the ability fully to understand or apply them.

This process is well illustrated in the case of psychology. The main outlines of Freud's methods, and the more general and simple of his conclusions, have met with a wonderfully ready acceptance from a large section of the intelligent medical and lay public. One no longer hears the phrase "the new psychology." It has become the ordinary, and, indeed, the only, psychology.

What the modern young person does not know about complexes, projection, sublimation, and all the rest of it seems hardly worth knowing. And why not? It is always something to have the glad tidings accepted at all, and one cannot fairly complain if a convert's enthusiasm occasionally outruns his understanding. In any case it is rather beside the point, because if we are to come to any conclusions about the application of psychology to medicine we must consider the process as it is carried out by the acknowledged psychological experts. To do otherwise would be less than fair.

What scientific psychology has to offer to medicine is the psycho-analytic method of investigation and treatment. I say "investigation and treatment" because, as you all know, the two are inseparable. The investigation is the treatment and the treatment is the investigation. So inseparable are they that, as Dr. Ernest Jones and others have pointed out with proper pride, diagnosis very often comes after treatment and not before it. Though there are those who would object to this state of affairs, I for one have no complaint to make of it. I view it simply as one of those "necessities of the case" which William James, in his innocence, regarded as calling for the services of a metaphysicist. Psycho-analysis must make her contribution to medicine in her own way. She has also the undoubted right to say who shall or shall not preach her gospel, or, at least, to decide what qualifications her missionaries require. She seems to me to be disappointingly reserved in her account of what manner of man her champion must be, but that is her own affair. I suppose that one should not even criticise her requirements, but I have ventured to make a few comments on her list. It is a short list, but after a reasonably careful search I can find nothing to add to it.

THE EQUIPMENT OF THE ANALYST.

Firstly, then, the medical psychologist must undergo "a laborious special training, demanding at least three years incessant practice." I presume that he obtains the special training from books. As regards the three years incessant practice, it is not quite clear where he obtains his material—perhaps from among the deserving poor. In any case the rule seems an admirable one, and I should be glad to see it come into force.

Secondly, he must possess, before beginning this training and practice, "a good knowledge of neurology." The precise reason for this particular stipulation eludes me at the moment, but one can commend it heartily on general principles. At the least it is a graceful courtesy towards the art of medicine. It is indeed the one and only concession which the psychologist is specifically asked to make to the vast subject which he is approaching, and as such it has every claim to honourable mention.

Thirdly, the medical psychologist must himself have been analysed. This, although it is by no means universally observed, seems an eminently reasonable condition to make. It is one more of those "necessities of the case" which keep cropping up. Not being a metaphysicist, I must refrain from dealing with the delightfully interesting questions which it raises. I shall not even propound them. Personally I am entirely in agreement with the poet who says, referring to psycho-analysis, "Only those who brave its dangers comprehend its mystery." It is true that the poet is ostensibly referring to the sea, but, as we all know, the sea is a universal symbol of the unconscious, and his real meaning is thus quite clear.

Finally, the psychologist must have certain personal qualities of which patience, unimpeachable integrity, tact, and sympathetic understanding are those officially recommended. Such qualities are obviously ornaments to any man, though I confess that I had never regarded the two latter ones as being essential to, or characteristic of, a devotee of pure science. I learn *from* Dr. Ernest Jones that without these qualifications the psychologist may fail to "gain the patient's confidence to the requisite degree." But this will never do. If there is one thing with which a scientific method has no concern it is surely the gaining of people's confidence by one's personal qualities. That is work for an unscientific and inferior order of beings.

In the very paper from which I have just quoted, and almost on the same page, we read: "In *suggestion* treatment the physician adds something to the patient's mind—confidence, belief, &c. The psychoanalytic method does not add. It is in almost every respect the reverse of treatment by suggestion." I cannot reconcile these two quotations. It looks very much like more work for our metaphysicist. Perhaps I should say, in parenthesis, that if anyone cares to object that I am quoting from a very old paper, I reply that I freely admit it, and that I hope to *tell* you why before I have finished.

However, if the psychologist really desires the graces of tact and sympathetic understanding it is not for others to suggest that he may put them to such base uses as that of gaining a patient's confidence. Let us rather rejoice that he adds these virtues to his unimpeachable integrity and his good knowledge of neurology, and let us consider how this "verray parfit gentil knight" will fare in his great adventure of applying psychology to medicine. Our knight-errant's venture, I am sorry to say, is a failure. It is rather a splendid failure, because he kills any number of dragons, he does little or nothing that is *actively* harmful, and he does a great deal that is helpful and wise and good. But he fails for all that.

PSYCHOLOGY AND "OBJECTIVITY."

There are various points of view from which the comparative failure of analytical psychotherapy can be discussed. The first one, which is staring us in the face, is the question of the attitude of the psychotherapist to the patient he is about to treat. Scientific psychology has not the slightest hesitation in defining that attitude. The goal to aim at, we learn, is complete objectivity on both sides. This is admittedly difficult for weaker brethren, and it did not greatly surprise me to learn from Dr. Glover that "every psychotherapist at one time or another is aware of a tendency to backsliding." The two commonest wanderings from the straight and narrow path of objectivity are, apparently, "flirtation with endocrinology," and "an impulse to give the benefit of the doubt to organic factors in illness." These are indeed regrettable lapses. I can only say of the first that boys will be boys, and of the second that it looks as if the good knowledge of neurology were already *proving a* double-edged weapon. What happens, by the way, to the tact and sympathetic understanding I cannot tell you. I presume that they fly out of the window as objectivity enters the door.

The purely objective attitude is, of course, the only right and proper one for a scientific inquiry. It is the ideal way to approach, say, a fossil, or—to be strictly accurate—for two fossils to approach each other. As between two human beings, ill or well, I should have thought that its utter *impossibility* would have been obvious to anyone with the very slightest experience either of medicine or of real life. But the psychologist cannot alter his attitude when he comes up against real life. To do so would be to destroy an admirably sound scientific edifice. If the facts of life will not fit in, so much *the worse* for them. And so it happens that his position sometimes comes to resemble that of the research physiologist whose experiments so often work perfectly in a test-tube and fail completely in the human *body*.

But we are in a stronger position than the physiologist. He cannot say, with any hope of being generally believed, that the human body is the same thing as a test-tube, but we can, and do, talk about "the series of events in space-time that constitute the living self." Many people will accept this statement without pausing to inquire what, if anything, it means. A few will realise how it recalls the delicious and polysyllabic fragrance of Herbert Spencer, and hardly any will have the courage to tell us that as a way of looking at medicine or life it is an academic and old-fashioned absurdity. But it certainly helps to justify the attempt at objectivity, which is always something.

Now there is a certain proportion of medicine
of life which comes into the field of vision even of
man who thinks that to study life is to look with
complete objectivity at "a series of events." With
this amenable proportion the psychologist deals
admirably well up to his limits. With the much
greater proportion which he misses he deals in a way
which is hardly so creditable. He ignores it, as far
as he possibly can, and when to ignore it be
impossible then he misinterprets it or explains
away. The attitude of objectivity thus seems to
get us into difficulties from the outset, and I must
refer to some that arise from it before proceeding to
other aspects of our subject. They can be summarised
easily enough. Psychology is a science, medicine
is *an* art. It follows that when psychology has
given all she has to give it is only the purely scienti
aspect of medicine that can possibly benefit. A
in every medical operation, down to the simpl
piece of therapy, there is an inevitable mixture
science and art. There is a scientific basis, there
a scientific technique, and there is—or ought to be
an element which, because it is art, defies analy
but without which results are apt to be comm
place and incomplete.

I need not tell you that psycho-analysis does
accept this view. It cannot see any necess
difference between the attitude of a physician
patient and that of a psychologist to his pr
It will never admit that there can be any el
in any human relationship which is incapable of
scientifically analysed and explained.

PSYCHOLOGY AND "SUGGESTION."

Well, of course, there is, as we all
psychologists included—and it is here that
begins. The psychologist finds before he h
tackled half a dozen patients that by far
vital and potent factor in his relation wit
and his treatment of them, is something abo
his psychology is silent and with which even
knowledge of neurology does not seem to h
Let me digress here for one moment to beg
to misunderstand me on the question of
medicine. For unscientific medicine I have
contempt and I have an even greater one for th
brood of so-called "pseudo-sciences" whic
round it. There is nothing worthy in medici
is unscientific, but there is a very great deal in
which transcends science, and which scien
as yet explain or apprehend. Particularl
true in psychological medicine, and, a
saying, this is a fact which modern p
cannot and will not grasp.

When I said a moment ago that she
on the subject, I was speaking something les
truth. She is, of course, very far from si
forgets that there is nothing unscientific
unable to explain a fact, and that indeed, th
business of science is not to explain facts, bu
and observe them. She puts every single fa
connexion that she cannot fully explain
enormous heap—a rubbish heap—and on the
the heap she plants a banner with the strange
"suggestion."

The thing now proceeds on lines which ps
analysis has itself made only too familiar to
The fact that something exists which we don't
stand is, of course, intolerable, and the
mechanisms come into play. A compreh
explanation of "suggestion" is evolved, which
the psychologist the most ample grounds for
beside his banner the red flag of "danger." Conc
this [illegible] o you [illegible] if I call it "

technical name and say "this rationalisation?"—I have only to say without hesitation and with every hope of violent contradiction that it is probably the most sadly inadequate performance of which any science has ever been guilty.

But the matter does not end here. Though the psychologist has now a respectable "reason" for disliking "suggestion," yet he goes erring after it time and again, partly because he wants to, and partly because he cannot help it: it is a necessity of the case—of every case. This sad but familiar state of affairs may, I think, legitimately be termed a conflict. Officially—or consciously—the psychologist shuns "suggestion" like the plague. Unofficially—or unconsciously—he coquettes with it daily. Need I tell you the inevitable result? I don't mean minor results such as the lapsus calami which I quoted to you, but the main psychological result. It is simply the mechanism of an obsessive fear writ large. Psycho-analysis and its disciples are suffering from a psychoneurosis—a compulsion neurosis. The word "suggestion" is to them precisely what a red rag is to a bull—and for many parallel reasons.

Although I have dealt with this at some little length—the treating of people, however inadequately, with their own medicine being always attractive—it is really only the approach to a number of more important and practical questions which arise when we come to consider the actual treatment of patients by the psycho-analytic method. We have to deal with people who are sick in a particular way: people who may be described generally as suffering from mental disharmony of some kind or other. Our problem is a thoroughly practical and clinical one—what has scientific psychology to say to the victim of mental disharmony?

THE AIMS OF ANALYTICAL THERAPY.

Fr tells him first of all that with his coöperation
repro disentangle and lay bare the very roots of
spite o that it can make him realise the sources from
collectin is thoughts arise and the machinery by which
of the d s. Such a realisation, it continues, will dissolve
order o he inhibitions, the make-believes, and the
spirit of ties which cloud thought and hamper conduct,
of the will become a man who sees himself as others
which i or even more clearly, and who sees life steadily
and is ole. Finally, and best of all, the psycho-
carry a symptoms which were the result and the
remains mental disharmony will disappear as mental
of teste is restored. That is the essence of
with he gy's contribution to medicine; that is its
every d to the sick man. The message is, in the

to do the arrel with it is of a different nature, and as
I need n above points are concerned I am quite
once give without prejudice—to take it at its own
perty of for the present. Besides, I very largely
very sho th that valuation. I believe that in a
average of cases psycho-analysis is more likely than
any other method permanently to remove a given psychoneurotic symptom.

But we shall all be agreed that that is but a poor compliment. The mere removal of symptoms is a small matter—do not even the suggestionists the same? Analytical therapy's self-imposed task and method is the disentangling and rearranging of the whole mental life of the patient, so that psychoneurotic symptoms become an impossibility. Neither is there salvation from neurosis in any other method. The whole thing is admirably logical and scientific. It is like an infinitely skilled workman dealing with some intricate and delicate machinery which has gone wrong.

There is bound to be an ascertainable and remediable cause for the irregular functioning so long as the laws of matter and motion remain. Yes, here it is; the friction is eased, or the foreign body removed, the parts are reassembled, and off we go again. Unfortunately, human beings are not constructed on the lines of a motor-car, or an eight-day clock, and they are just as incapable of completely scientific psychological analysis as they are of purely objective psychological approach.

THEORY AND PRACTICE.

What exactly do we find when we begin to dissect the mind of John Smith? We find, for one thing, that he is a mass of ideas, prejudices, reactions, and beliefs, many of which are utterly irrational and are constructed on similar lines to psychoneurotic symptoms, differing from them, I suppose, only in degree, if at all. In any case, he certainly cannot be analysed and save these things intact. Down must come the entire structure. It was a queer shape, anyhow. True, it made up what he called his personality, but we can't help that. One must break eggs to have an omelette. And then—though we are debarred from giving him advice or assistance in the task—he can always re-educate himself to a more practical sort of personality, just as the omelette re-educates itself into a square egg. I know of but one recorded instance of this double metamorphosis being attempted with an egg—namely, the classical case of Humpty Dumpty. In that case the re-education was a failure, even with military help, but possibly John Smith may be more fortunate.

Let us take down this absurd looking old cabinet. I have borrowed it from another writer for the purpose. It is composed of hundreds of pieces of various woods, many of them very valuable, but its shape is wrong, the drawers work badly, and the mosaic pattern of the inlay has not been symmetrically arranged. As we proceed even graver faults in construction become apparent. The stresses and strains are all improperly distributed. Here is a stout cross-piece bearing nothing, and there is a lid which is only supported at all because two uprights have fallen out of place and are holding a weight for which they were never intended. However, we shall soon ease that. There is the whole thing on the floor at last. *Requiescat in pace*—or to be literally accurate—*in pacibus*.

Now for the reassembling. Strictly speaking, the new design ought to be specified by the cabinet itself and not by us—it should be a self-governing cabinet—but I waive that point. In a very short time we shall be only too thankful to put the thing together to any design at all. And at the end we shall be left, like the boy who analysed his watch, with half a dozen pieces that don't seem to fit in anywhere, but the cabinet somehow is not the same without them.

Is everything a neurotic symptom which is constructed as such symptoms are? Is everything which crumbles during an analysis a neurotic symptom? Is every irrational reaction or idea or belief a neurotic symptom? If so, what exactly *is* a neurotic symptom? If not, is it good that these things should be dissolved away, and is the analysed or unanalysed state the more healthy?

Be these things as they may, it is very certain that, apart from any "symptoms" he may show, John Smith's life is largely composed of irrationalities, which to him and for him are real and practical truth, and upon which his efficiency and health depend. All the logic is on our side, but the man is incorrigible. We put him right on the facts of life before birth in which he ought to believe but does not; we put him right on the legend of life after death, in which he ought not to believe, but does, and he might at least, one would imagine, live and think according to our logic between the cradle and the grave. But will he? By no means. We tell him, for instance, all about the dangers and terrors of authority, we instruct him regarding infantile attitudes and reactions, and we preach the gospel of psychological independence. And all of it is true enough in its way. But John Smith is horribly practical. He knows all about authority—he was once an office-boy. He believes, with Johnson, that "no two people can be half an hour together, but one shall acquire an evident superiority over the other." His common sense tells him that personality needs a soil in which to flourish and a background against which to be displayed, and that unless the world is to be peopled exclusively by Mussolinis authority will be a reality in every department of human life till the end of the chapter. At least it is a reality, and a gladly accepted one, to him. The same is true of many more of his irrational components. They are the left-over pieces. We have proved that he can be reconstructed—after a fashion—without them, but they were real and essential to him, and he knows how to make use of them. They were his—and will we please give them back.

PSYCHOLOGY AND BELIEF.

I want to go just a step further in this connexion before passing on, and to look for a moment at the objects, rather than the mechanisms, of irrational belief. To begin with, we all know that facts are of different orders and natures, and that in any study of facts by scientific method the scientist must begin by defining the nature of the phenomena with which he is going to deal. The phenomena with which the psychologist deals are conveniently grouped as mental. All the activities of mind and their outcome in behaviour are his province, and it is in connexion with those phenomena, and those only, that he should observe his facts, collect his data, and formulate and test his hypotheses. A patient has, let us say, various convictions and beliefs. These beliefs are psychological phenomena which should be carefully studied as such. That is to say, we can show the patient how his belief arose, whether his mental processes were as logical as he perhaps imagines, how he has rationalised, where he has been swayed by emotion, and so forth. We can, in short, expose and explain the entire machinery by which the belief has been produced, and the mental bases on which that machinery rests. What we cannot do, or rather, what we should not do, is to offer any opinion as to the truth or falsity of the thing believed.

When you have said all you have to say about my conviction that nine sevens are 63, and I then say: "Thank you, but as a matter of fact *are* nine sevens 63?" you have only one proper course—namely, to direct me to the nearest mathematician. The debate is now upon a mathematical question, not a psychological one, and has passed out of your domain into his. To that illustration, which, by the way, is borrowed, there is the reply that in it the mental processes are logical and the conclusion demonstrably sound. But neither fact makes the slightest difference to the principle. The principle still holds if I say, for instance, that my school was the best one, or that my university was the most modern one, or that my system of psychology is the only scientific one. If I tell you these things you may very properly draw certain inferences about me and my mental processes, but you have no business, as psychologists, to deny or dispute my conclusions. I may conceivably be right.

It is surely obvious that our concern should be only with the means by which a belief or opinion was reached. However faulty, insufficient, or absurd these means may have been has no bearing whatever upon the objective reality of the thing believed. That is a question for the appropriate department of knowledge: history, or mathematics, or astronomy, or perhaps the universal testimony of human experience. To all this you may reply that I am needlessly elaborating an elementary point, and discussing an error into which no good psychologist would fall. But failure to look carefully at the elementary points and to discuss them fully has been responsible for more misunderstanding than anything else in psychology. That, by the way, is my justification for lecturing on first principles to an audience of experts. The besetting sin of every medical psychologist is that he insists on running before he has learned to walk. He does more than run, he skates, and it is sometimes over very thin ice. As regards the frequency of this particular error I will only say that when we find, as we so often do, that something in which a patient believes is an externalisation of what he wants to believe, and that his conviction of it is produced by the familiar irrational mechanisms, then we are almost irresistibly tempted to deny to the thing believed the possibility of an independent objective existence.

We yield every day to the temptation to pass judgment on matters with which our psychology has nothing to do, and to confuse the mechanism of belief with the object of belief. A mental conception—a phantasy, if you like—can perfectly well have an independent objective counterpart as well. After all, many objective realities began as psychological ones, if you come to think of it. Although I may apprehend a reality in a round-about and fallacious way, it may exist none the less. It is very possible that in the first instance I believe something to be true because I ardently desire it to be true, and because it would meet my psychological needs if it were true. But does that necessarily make it false or non-existent? It is possible, you know, that realities exist which are suited to our psychological needs, and if it is a question of the fundamental psychological needs of every man and every age, then I think the possibility becomes a probability.

PHANTASY AND REALITY.

Things may exist even though we hope for them. Occasionally, even in real life, a story may have a happy ending. There was once, for example, a small barefoot boy who, stimulated by the effects of stones, nettles, and broken glass, told his companions a silly little childish phantasy of some wondrous place where the floors were of smooth rubber, where neither nettle nor glass might enter, and where there should be no more gravel. And in this strange heaven, said he, there lived one who knew about feet and who cared for them, and who would give to his feet and to those of all who came there a wonderful covering, a protection from pain and cold and wet, a foot-joy such as it had not entered into the sole to conceive. And his companions who were psychologists in the making but were not yet perfected in the tact and sympathetic understanding so necessary to their profession, laughed at him. And the boy cried himself to sleep. And in the morning his father took him to a bootmaker's shop. And there he found not only boots beyond his imagining, but, strangely enough, a pair that fitted his feet and might have been made for them alone, as it were from the foundation of the world.

Nobody considers it impossible, or even remarkable, that things should exist which satisfy our bodily needs. Did you ever think of that marvellous and illogical character, the man who, craving for carbohydrates, found and ate the first potato? What a venture of faith! Almost anything might have happened. What did happen was that when he got home his wife, who was a psychologist but had only a fair knowledge of neurology and none of physiology, explained to him that the potato did not really exist, and that if it had existed it would probably have poisoned him. And the man said that he wished it had. The friends of Christopher Columbus told him that America was simply his phantasy, an externalisation of himself which had no objective existence outside his mind. When they found they were wrong they were much disappointed. Some people are a little disappointed still, but the fact remains that America was not an invention; it was a discovery.

We may note, by the way, that a similar kind of error tends to creep into our dealing with symbols.

This has often been pointed out before, and I do not propose to discuss it at length. All I have to say about it at the moment is conveyed by the story—which deserves to be better known—of the precocious little school-girl who laughed and giggled in the class when the teacher announced a lecture on wading birds, of which the first was the stork. When asked to explain her mirth, she replied with a knowing smile: "Oh, but teacher . . . the idea of there really being any storks!"

Father's mashie was several different things at the children's charades last night. It was an oar, and a putter, and a sceptre, and a fishing-rod. Nevertheless it retains an independent existence as a mashie in its own right, and is, in fact, the actual weapon with which father hacked his way to victory at the seventeenth hole on Sunday, though I admit you would never have thought so to look at the charade, or at the mashie, or, for that matter, at father. But this is rather a digression. If I am not becoming wearisome to you, I should like to consider one more aspect—perhaps the *chief* and central one—of the inadequacy of the psycho-analytic method of treatment.

THE INADEQUACY OF ANALYSIS.

Let us return for a moment to our rough analogy of the wooden mosaic cabinet. I do not wish to push it too far, but I may point out that something has eluded us in our analysis of it. The most important thing of all has eluded us—namely, the glue. We can testify to the strength with which it resisted our separation of the pieces, and to the fact that it looks as if it were all there still—but it will not stick the pieces together again. It has ceased to be adhesive. It will never be adhesive any more unless we add something to it, and, as we have learned, "the psycho-analytic method does not add"

Analytical psychotherapy shuts its eyes, of necessity, to many *of the greatest and most powerful realities* in human life. I say of necessity not only because it works, so to speak, on but one plane and by but one method, but also because it will not admit any realities in mental activity and experience unless they exist upon its plane, are amenable to its method, and can be expressed in its terms. Alone among the sciences it claims a universal applicability, and alone among the sciences it is never at loss. Its discoveries and truths are wonderful and helpful and fascinating, but when seen against the background of its own demanding—namely, the everyday life and health of men and women—they cannot help appearing what Mr. Alfred Noyes in some very striking verses calls "little truths." In a certain immortal allegory we read of a man who could look no way but downward, with a muckrake in his hand; a man who would neither look up nor regard, *but raked to himself the straws*, the small sticks, and the dust of the floor.

Now the usual uninformed and foolish criticisms of psycho-analysis are directed against the muckrake and the sweepings, with which I, personally, can see nothing amiss. The man seems to me to have done the most that could be demanded from anyone in his position. He used suitable apparatus, collected just what one would expect with it, and I have no doubt he left the floor a better place than he found it. Both his position and his implement made window-cleaning impossible. The limited nature of his activities was the direct consequence of his attitude, and it is his attitude to which I object. Such an attitude is bound, as I have been trying to show, to lead to misapprehensions, unwarranted assumptions, and incomplete results. But the greatest tragedy of it is the amount that eludes it altogether. The man does not realise the tragedy, because it never occurs to him to question his attitude, to expand his methods, or to admit his limitations. "I cannot see a sky," he says, "and my rake has never brought it along the floor to me. Therefore there is no sky, and that is the end of it." I fear that this attitude is a necessity of the case, both in the analyst and the analysed.

If, as I imagine, nobody has yet made a post-mortem psycho-analysis of Swinburne, in the approved manner, I beg to propose him as the next victim. Alternatively, if sciences have patron saints, I should put him forward for that office. I know of no one whose outlook shows so clearly both the strength and the weakness of the psycho-analytic position. In particular he possesses in almost unique degree the ability to make a desert and call it peace.

> "Though one were strong as seven
> Yet he with death shall dwell
> Nor wake with wings in heaven
> Nor weep with pains in hell."

The good cheer with which he enunciates this demonstrable truth is in quite the best tradition. And then, of course, we have the well-known lines:—

> "From too much love of living,
> From hope and fear set free
> We thank, with brief thanksgiving,
> Whatever gods may be,
> That no life lives for ever,
> That dead men rise up never,"

and so forth. Could the position possibly be better expressed? Note in particular the psychological independence achieved in the first two lines, the brevity of the transference phenomena, and the scientific caution of line four, merging into well-warranted confidence in the simple dogma which follows. Surely this is the sincere milk of the psycho-analytic word.

By way of contrast I should like to introduce to you the outlook of a very different, and, as I think, a more all-round character, whose creator, appropriately enough, is Mr. G. K. Chesterton. He is a knight, who rides "forever seeking after God," or, as we should put it, he is more interested in looking through the window than in cleaning up the floor. The fact that he may not be able fully to analyse or explain what he may see does not trouble him. He will experience it, and the experience will be none the less valid and real. But will he ever see anything? That I cannot tell you—not at present, anyhow. Shakespeare—or Hamlet—thought so, and the possibility is hinted at in an old-fashioned psychological handbook. And I think we must leave it at that. Besides, it is not the important point. We are not concerned with what he may or may not see. What really matters is that he has adopted an attitude and outlook from which vision is at least possible, and that the attitude makes for completeness and sanity and health, and is indeed essential for them. He is rather a fine fellow, this knight, though I fear that his sublimations and transferences need some attention, because there is in his eyes, he says . . .

> . . . . "the star of an unconquerable praise,
> For in my soul one hope for ever sings
> That at the next white corner of a road
> My eyes may look on Him."

Well, of course, if the man is going to talk that way we can't compete. It would be like inquiring the distance from roast beef to the square root of minus two. Our own familiar jargon, lying on the floor beside that rake, at least sounds as if it meant something, but when it comes to souls, and hope singing, then we give in. Unfortunately, we don't give in, as I have just pointed out, but let that pass. This knight of Chesterton's is at least a man, to whom life is a great adventure, surrounded with wondrous and mysterious possibilities, and is not a disgruntled machine to which life is a matter of complete indifference. Breathes there the man with—mind so analysed, that he doubts which is the happier and healthier and saner outlook?

SYMBOLIC AND INTIMATE KNOWLEDGE.

If psycho-analysis recognised any psychology but its own, I do not think it would be really difficult to clear up this matter of the truths which elude the analytic method. Is it not, in essence, a question of the two varieties of truths, about which William [illegible] has so much to say: the "innate" or "a priori" truths, as he calls them, of the sciences, and the utterly different "truths of experience" or, if you prefer to go back to Locke, "mental" truth and "real" truth?

In Dr. Eddington's wonderful book "The Nature of the Physical World" there is a chapter on Science and Mysticism in which he discusses the same question, using the *terms* Symbolic knowledge and Intimate knowledge. "Intimate knowledge," he points out, "will not submit to analysis; or, rather, when we attempt to analyse it the intimacy is lost and it is replaced by symbolism." In that one sentence the necessary inadequacy of psycho-analysis is unanswerably set forth. If only this were admitted, how the value of its great work would be enhanced. Dr. Eddington gives a wonderfully happy illustration. He supposes, he says, that humour and wit can be analysed. Well, we can all assure him that he is quite right there. He then points out that after a sample of humour has been duly analysed and passed as a joke, the next thing to do is to laugh. "But it may *certainly* be predicted," he says, "that as the result of this scrutiny we shall have lost all inclination we may ever have had to laugh at it. It simply does not do to expose the inner workings of a joke. The classification concerns a symbolic knowledge of humour which preserves all the characteristics of a joke except its laughableness." And that is why psycho-analysis, though not of Scottish ancestry, misses the point of every joke it touches.

Now there are very large departments of life where intimate knowledge flourishes and symbolic knowledge is at a discount. It is when it insists on tackling these that the psycho-analytic method is specially apt to make itself look ridiculous. It becomes hope*lessly confused, for example, between the symbolic* knowledge which is theology, and the intimate knowledge which is religious experience. We cannot now discuss this great subject, but I may take a final illustration from it.

A great many years ago a company of working scientists made a singularly complete reductive analysis of Jesus of Nazareth. I do not suppose that as they carefully divided his clothing they imagined it possible that anything had eluded or escaped them. But something did escape them; something which for 2000 years has done more than any other single factor to influence individual characters and national destinies. I am not now concerned with the nature or the value of this something, but with its reality and potency. I merely state a fact which, if any sane person doubts, he can confirm by reading half a dozen biographies or a history book. Modern psychology, however, has but one method to apply to this unique phenomenon. Armed with our sword of science, and strong in our unimpeachable integrity and, of course, our good knowledge of neurology, we march forth to apply our instruments of precision to what is probably the *greatest truth* of experience. We go one better than our Roman predecessors, for we tear into futile
strips not the garments nor the body [illegible] haracter
and mind of that supreme person [illegible] we sa
"behold the man." We, too, are c [illegible] nothi
has eluded us, because—nouveaux [illegible] we are
we have not learned and will not [illegible] here
aspects and regions of reality [illegible] meth
can never apprehend.

PSYCHOLO [illegible]

And now what do [illegible] p
of view of medicine [illegible] th [illegible] fr
any other conside [illegible] ot
[illegible] ct with the vit
[illegible] sed and
[illegible] s, is bound
[illegible] nt. The
[illegible] t psycho-
[illegible] life of or
[illegible] much abo
[illegible] paradox, t
[illegible] psycholo

out with machine-made uniformity and mathematical precision. Even its deepest researches and truest discoveries have little practical and helpful relation to the life of experience. As far as John Smith is concerned, the Ego, the Super-ego, and the Id have just about as much to do with his life as the three-card trick has to do with the Derby.

John Smith does not want a system that explains everything; he feels that it would cramp his cosmos and make him think that there was nothing worth explaining. He is not thrilled by the prospect of saying "I understand and I am not afraid." He thinks that it is equally fine, and much more likely to be true, to say "I do not understand and I am not afraid." He has no objection to a poet telling him that hope is singing in his soul, though he wouldn't have put it that way himself, and he is quite prepared to add faith and charity to the orchestra. Another poet has referred to this irrational trio as "the music of the dream that never dies," but those to whom the journey from floor to window presents insuperable difficulties find it simpler to call them "transference phenomena."

I would point out, in conclusion, that in the present trend of psycho-analytical writings we find very striking examples and results of its detachment from practical life, and therefore from practical medicine. The writers seem to turn away from the clinical side of the subject as if aware of its incompleteness and sensing its pitfalls, to wander in the happy hunting-grounds of scientific speculation and research. The actual illness of the patient is sometimes referred to in a way which leaves the impression that the writer's main concern is to get busy with a description of what he has learned from the case, or an account of the principles which it illustrates. These are perfectly legitimate topics, and I quite agree that if a writer's medical equipment happens to consist solely of a good knowledge of neurology, one must be prepared to make allowances, but the high proportion of this kind of work is an interesting and significant fact nevertheless.

I said I would tell you why I quoted from an old paper. It was for the good reason that nowadays papers on practical medical psycho-analysis are almost impossible to find. I thought I had found one a few weeks ago, but as I read on it became clear that the author had not so much as seen the patients whose reactions he was describing.

Not long ago I heard two brilliant papers read during a discussion on a strictly clinical subject, but so far removed were they from the matter under consideration that when they came to be published their very titles had to be changed. While I would not go so far as to compare our psychological knight-errant with Sir Andrew Aguecheek who was dubbed, if you remember, with unhatched rapier and on carpet consideration, although a devil in private brawl, yet I do suspect him of spending more of his time over his well-known text-book on "The Principles of Dragon Hunting" than in single combat with individual
[illegible] ons. This is by no means to his discredit. It is
[illegible] last and final necessity of the case. He has been
[illegible] than useful as it is; he has been essential. His
[illegible] is simply that he cannot realise his incomplete-
[illegible] or admit so much as the possibility of coöpera-
[illegible] ith some one, let us say, like St. George, who,
[illegible] l his faults, has been trying to slay dragons in
[illegible] cal if empirical way for quite a long time.

[illegible] will please remember very specially that in
[illegible] have jus [illegible] ying, and in the little I have
[illegible] say, I [illegible] ularly referring to Freudian
[illegible] nalys [illegible] e, original, and—as I think—
[illegible] ed m [illegible] erwise, it would, of course,
[illegible] say that psychology, even
[illegible] but little practical and
[illegible] y life and experience. But
do [illegible] the intimacy of that
[illegible] Freudians disown.

[illegible] t [illegible] it is inevitable that psycho-
be [illegible] less prominent as a means

of therapy, and ever more effective and far-reaching and profound as a system of psychology. But if it were never applied to another patient clinical medicine still owes it a debt which it would be hard to overestimate. We need not discuss the reasons why the acknowledgment of that debt has been perhaps somewhat lacking in readiness and cordiality. It is possible that there may be faults on both sides. I should be sorry to leave the impression that I, for one, did not feel the debt keenly and acknowledge it frankly, and I trust that any apparent flippancies in my remarks have not exceeded the amount which is not merely allowable, but needful, if an address of this unconscionable length is to be tolerable at all. As for my more serious criticisms, psycho-analysis is only too well able to look after itself, and, in any case, I respect it too much to be insincere.

PSYCHOLOGY AND MYSTICISM.

Until psycho-analysis can acknowledge and overcome its limitations, it cannot be what it claims to be: a complete, self-contained, effective, independent contribution to—indeed, a synonym and substitute for—the great art of psychological medicine.

Psychology is not an art; it is only the hope of an art. It is waiting for a greater than Freud—not necessarily a greater genius, but certainly a greater—because a more complete—man. When he arises, the necessities of the case will make him what we should now call something of a mystic, because his great work will be to connect scientific truth in some unimagined way with those great realities of experience apart from which mental life is a mechanical rattle, and mental health an impossibility. He will relate the machinery of mind, as never before, to every fact of life and of experience. It may seem a hard thing to say of him, but I expect he will believe in God. Otherwise I cannot conceive how he will succeed in reaching across the gulf between science and mysticism, between symbol and reality. One can hardly imagine that that gulf may ever be bridged and the road run clear from knowledge of mind to understanding of life and of the mysteries that lie in and around and beyond it. But should it conceivably happen, then science will have achieved her supreme triumph, and one need set no limits to its possible results.

One cannot readily picture the lines along which this great scientist will work nor the discoveries he will make. We can be sure, however, that he will *not be false to science as we know it, though he will* so enlarge its vision and scope that it will become a means of apprehending truths at which now we can only guess. When I think about this new and great scientist, I like to remember that new truths sometimes have a way of turning out to be simply old ones, expressed from a different viewpoint and in words more suited to the time. Remembering this, I sometimes wonder whether the wheel might conceivably come full circle after all, and whether science's last and greatest discovery might possibly—just possibly—prove to be a restatement, in much better words, of course, of something which was said by a great mystic long ago: that "God created man for immortality, and hath set eternity in his heart."

An Address

ON

PITFALLS IN UROLOGICAL DIAGNOSIS.

Delivered at St. Mary's Hospital Post-graduate Course on Oct. 6th, 1929,

BY R. M. HANDFIELD-JONES, *M.C.*, M.S., F.R.C.S. ENG.,

SURGEON WITH CHARGE OF OUT-PATIENTS, ST. MARY'S HOSPITAL; SURGEON TO THE MILLER HOSPITAL AND TO THE PRINCESS LOUISE HOSPITAL FOR CHILDREN.

ACUTE PYELITIS.

ACUTE pyelitis is an infection of the mucous membrane of the pelvis and calyces of the kidney most frequently caused by the *Bacillus coli*. The severity of the condition varies considerably. An unrecognised acute pyelitis can lead to a chronic condition, which may prove to be most intractable. The great importance of early diagnosis is illustrated by the following case:—

A British officer, while serving in Mesopotamia, was suddenly taken ill with severe pain in his left side, a high temperature, and rigors. The diagnosis was *sandfly fever*, and the local symptoms were referred to an enlarged spleen, which was said to be present. He came to see me in 1924, when he had been overhauled and chronic pyelitis had been correctly diagnosed by many surgeons, but his symptoms had not been relieved. A routine urological examination revealed a left kidney infected with *B. coli*, a right kidney free, and the bladder unaffected. For one year he showed marked improvement and then suddenly relapsed. I asked Mr. Girling Ball to see him and he was advised to have a nephrectomy done as the only hope of clearing up his symptoms. Before this could be arranged he nearly died of hæmorrhage from an acute hæmorrhagic cystitis. Finally, in 1926, a left nephrectomy was performed and the patient is now alive and well. But his history shows what disaster can follow a missed pyelitis.

The symptoms of acute pyelitis are pain, vomiting, high fever, rigors, pyuria, and later frequent and painful micturition.

Pain.—This always starts in the side or lateral part of the abdomen, and is often described by patients as being situated in the iliac fossa. Never at any time is it referred to the central area of the abdomen. When the attack is established the pain is about the level of the umbilicus, extending from the outer edge of the rectus sheath round the loin to the margin of the erector spinæ. There may be typical referred pain in the groin, labium, scrotum, and down the thigh. It is continuous and not colicky. The severity of the condition varies considerably and cases are therefore classified as mild, severe, and fulminating.

Vomiting.—In most cases in the early hours of the attack there will be a single attack of vomiting, usually immediately after the onset of the pain.

Fever and Rigors.—The temperature is always high and may reach 105° F., and rigors are the most important diagnostic sign. I have never seen an acute pyelitis without a rigor.

Frequent and painful micturition are evidence of bladder irritation and are seen only after a few days, and then only in severe or unrecognised cases.

Pyuria.—In every case pus will be found in the urine, but at the beginning of the attack, when the diagnosis is in the balance, pus is in small amount only, and the more severe the case the less will there be at first.

Differential Diagnosis.

The diagnostic pitfalls are many. The right kidney is more frequently affected than the left in every unilateral renal lesion, and it is in the right-sided pyelitis that the difficulties are greatest. The appendix is at hand, the mimicry of its symptoms is not to be questioned, and acute appendicitis is a very common disease. Moreover, since the one condition demands immediate operation and the other is aggravated by unnecessary operation, the diagnosis is really important. We are here confronted with a clear-cut issue. It is not a question of there being something inside which demands exposure, but of the presence of a lesion which can be easily treated medicinally, and which can become a severe menace to health if unrecognised. I submit that if certain principles are kept ever in sight the diagnosis need never be in doubt. The points to remember are:—

1. In acute appendicitis the pain always starts centrally in the abdomen around the umbilicus and spreads in time to exact localisation in the iliac fossa. In acute pyelitis the pain starts in the side.

2. In appendicitis a raised temperature is common, but not to the same height as that which characterises acute pyelitis.

3. No uncomplicated acute appendicitis ever has a rigor. No acute pyelitis is ever without one.

4. The urine should be examined. It may seem futile to discuss the pitfalls of diagnosis in acute pyelitis when an examination of the urine will settle the issue. But all of us can recall cases where the urine was forgotten. A quiet unoffending appendix may have been removed and days later, when frequent and painful micturition is noticed following appendicectomy, the pyelitis is regarded as a complication. But in truth the pyelitis is not a complication but the primary lesion. James Sherren once said that every bed should have a finger-stall suspended beside it; he might have added the suggestion that the abdomen of every patient should have emblazoned on it in the letters of imagination "Forget not the kidney." There are other conditions which may cause difficulties in diagnosis—e.g., gall-stones, cholecystitis, and other renal lesions. But the appendix is the chief villain of the piece.

The fulminating type of acute pyelitis is of so sudden, so dramatic an onset, and so disastrous a severity that it may be mistaken for a perforation of an ulcer, acute pancreatitis, and so on. The following case illustrates this:—

A young woman, who had been married about a year and lived abroad, was in London on a visit and dining with a large party at a restaurant when she suddenly collapsed. She vomited and was removed to a nursing home, where she was found to have a temperature of over 105° F., intense pain, and rigidity on the right side. Several diagnoses were suggested, but the occurrence of rigors and the presence of pus in the urine clinched the matter and the patient's return to health was rapid.

HYDRONEPHROSIS.

The next pitfall in urological diagnosis is hydronephrosis. The well-established type with a large sac presents a classical picture. There are recurrent attacks of pain in the side, followed by a distinct diminution in quantity of urine passed and the gradual appearance of a tumour in the loin. Later, with the relief of the obstruction, comes the passage of great quantities of urine and the subsidence of the tumour. This definite clinical picture is the one described in text-books and manuals of urology whose authors tend to overlook the fact that every hydronephrosis must have a beginning in a normal kidney, and that there is a long way to go before a large sac is formed. The first change in a kidney in commencing hydronephrosis is the obliteration of the indentation of the pyramid into the calyx, which, therefore, becomes clubbed and not cupped. But this gives but little added capacity to the pelvis, and no general enlargement of the kidney occurs. It is well worth diagnosing these cases early, because as the hydronephrosis enlarges, the kidney cortex atrophies and may finally become a mere shell; the earlier the diagnosis the less interference with renal function. In the early cases pain is the only symptom, and they fall into an acute and a chronic type. In the acute type there is a sudden onset of acute pain in the side, a single attack of vomiting, without fever, rigors, or any urinary changes. In the chronic type there are recurring attacks of pain, which is gradual in onset and less severe, and rather a dull aching pain in the loin, with a complete absence of any other symptoms.

The diagnostic pitfalls are numerous, but perhaps the most common is to mistake the chronic hydronephrosis for a chronic appendicitis. I myself am convinced that there is no such condition as chronic appendicitis in the absence of a previous acute attack, but I am aware that all surgeons would not go so far. In any event no case of chronic right-sided pain should be labelled chronic appendicitis until every other possible diagnosis has been adequately explored. If the possibility of a hydronephrosis is thought of, its presence can be proved or disproved by a pyelographic examination, a simple procedure for everyone concerned, including the patient.

SYMPTOMLESS HÆMATURIA.

Blood may be present in the urine in addition to other abnormal constituents, and with symptoms which make diagnosis easy. There is, however, one group of patients in whom hæmaturia is the only symptom. The blood comes either from the bladder, when a simple cystoscopic examination reveals the source and nature of the trouble, or from the kidney. For renal bleeding we are almost entirely dependent on the vision of blood coming from one ureteric orifice for localising the lesion to one side. It is true that X rays, with or without pyelographs, may reveal the cause, but in a large group of cases the blood must be seen by cystoscope, and the problem is to get the patient examined while he is still bleeding. Often he comes to see us bringing with him a specimen of urine full of blood, but a fresh specimen reveals none; in other cases cystoscopy is delayed so long that a negative examination results. Patients must be instructed to come for examination the moment they see their urine becoming red, even if it means leaving work; and when they present themselves a cystoscopy must be undertaken at once. The need for hurry is the fact that many of these patients are bleeding from a renal new growth.

The way in which blood is passed, whether before or after or during micturition, whether pure blood or mixed with urine, is of no diagnostic import. One point, however, should be noted. Occasionally a clot will be passed, long, cylindrical, and worm-like. This is a ureteric cast, and is pathognomonic of a renal neoplasm. The following case shows the difficulties in symptomless hæmaturia.

A man, aged 56, was seen after an attack of blood in the urine. A complete urological overhaul, including a double pyelography, revealed nothing. On four subsequent occasions he came one, two, or three days after bleeding, always with a negative result. At last I insisted upon his coming up the instant he noticed anything. This time he noticed blood in the urine before a luncheon interval at work. He left his office at 1.25 P.M. and was on the table being cystoscoped at 2.5 P.M. Blood was seen pouring from the right orifice, but it now no longer interested us because a nodular tumour of his right kidney could be felt. This proved inoperable, and although he came first at a period when the tumour must have been removable, nothing short of exposure of both kidneys could have given us the diagnosis.

This case shows the urgent necessity of investigating a hæmaturia at once, and not only within 24 or 36 hours.

CONCLUSION.

In conclusion, let me draw your attention to one method of investigation which is of particular interest in renal lesions—viz., the hyperæsthesia of the skin. Head's work mapped out brilliantly and accurately the skin areas corresponding to the different viscera. I must admit I have been singularly disappointed with the value of hyperæsthesia tests for any viscus save the kidneys. Renal lesions give a very high proportion of positive tests, and the areas should always be mapped out if present. No negative hyperæsthesia test is of any value, but a positive one may prove the conclusive piece of evidence needed. I hope I have succeeded in bringing before you a picture of some of our difficulties in urological diagnoses, and I shall be happy if I have succeeded in refreshing in your minds the teaching of your old teachers, that in every case of abdominal pain the urine should be examined, and the kidneys remembered as the possible source of the trouble.

THROMBOSIS OF THE SUPERIOR CEREBELLAR ARTERY.

INCLUDING REPORT OF A CASE WITH UNUSUAL CEREBRO-SPINAL FLUID REACTIONS.

BY C. WORSTER-DROUGHT, M.D. CAMB.,
M.R.C.P. LOND.,
PHYSICIAN TO THE WEST END HOSPITAL FOR NERVOUS DISEASES AND TO THE METROPOLITAN HOSPITAL;
AND
I. M. ALLEN, M.D. N.Z., M.R.C.P. LOND.,
SENIOR RESIDENT MEDICAL OFFICER, WEST END HOSPITAL FOR NERVOUS DISEASES.

THE case described illustrates certain interesting points in the clinical syndrome resulting from thrombosis of the superior cerebellar artery, and provides further material upon which the identification of that syndrome can be based. In addition, the changes in the cerebro-spinal fluid are sufficiently unusual to be worthy of attention.

The patient, a female aged 66 years, was admitted to hospital on Dec. 1st, 1928, complaining of loss of power in the left arm and leg, together with spontaneous movements of the left arm. These symptoms had been present for three weeks, but the total duration of the illness was five months. She had been in poor health for 12 months. For five months she had fidgeted with the left arm, had suffered from attacks of giddiness, and had vomited in the morning. During that time she had been very irritable and easily upset; and at times depressed and excited. Five weeks before admission she had complained of pain across the shoulders and in the left arm; then for two weeks she had suffered from "dermatitis" involving the body but not the face. For three weeks there had been gradually increasing loss of power in the left arm and leg, and the spontaneous movements of the left arm had become more severe. Speech had been a little thick during this time. Five years before she had had an attack of pleurisy and "congestion of the lungs." Shortly afterwards she had had an accident in which she cut the left eyebrow. She had been married 24 years. There had been no pregnancies. Of the previous marriage there were two children, one of whom had died of a spinal complaint.

Condition on Examination.

The pupils were small, the left larger than the right; both were irregular and reacted normally. Vision was good in the left eye and slightly deficient in the right eye. There was apparent narrowing of the visual fields on the temporal side, but a perimeter chart of the fields showed that there was moderate concentric contraction of both fields. The temporal halves of both optic discs were pale; the arteries were small and showed a white reflex; the veins were engorged and kinked where crossed by arteries. The ocular movements were normal and there was no nystagmus. In speaking some words were slurred but everything could be easily understood. Hearing was fairly good. Excepting for weakness of all the facial movements, the other cranial nerves were normal.

Cotton-wool, pain, and thermal sensibility were apparently less distinct in the left arm than in the right. The difference between the two sides was much more obvious in the arms than in the legs. Deep pressure was unaffected. In the left arm there was loss of the sense of position, vibration sense was absent, and localisation was defective. The recognition of size and shape was also defective in the left hand, but normal in the right hand. Because of the variability of attention finer changes could not be elicited. In the right arm motor power was fairly good, muscle tone was normal, and the deep reflexes were sluggish. In the left arm motor power was very poor, muscle tone was much diminished, and the deep reflexes were absent. In the right leg motor power was fairly good, muscle tone was normal, the knee- and ankle-jerks could not be elicited, and the plantar reflex was flexor. In the left leg motor power was much decreased, muscle tone was diminished, the knee- and ankle-jerks were absent, and the plantar reflex was flexor. The abdominal reflexes were all absent. The patient could neither stand nor walk.

Wavy, sinuous movements with a definite, slow pattern, but failing to reach an object if directed towards it, occurred in the left arm on attempts at effort or on emotion. There were slow serpentine movements of circumduction at the shoulder, pronation and supination of the forearm, flexion and extension of the elbows and wrists; flexion and extension of the interphalangeal joints with abduction and adduction of the fingers. With the finger-nose test, on the right there was a slight intention tremor with the eyes open, slightly increased with the eyes closed; on the left there was a pronounced intention tremor with exaggeration of the spontaneous movements, apparently resulting from them. It was impossible to test for Rombergism. Repeated alternating movements were performed clumsily in the right hand and arm and were impossible in the left arm. Rebound was fairly good in the right arm but exceedingly poor in the left. The initiation of the slightest voluntary movement in the left arm resulted in the whole range of the movement being carried out suddenly and the hand falling in a flail-like manner against the face, the body, or the side of the bed. There was definite decomposition of movements and dysmetria in the left arm. An attempt to hold the arms horizontally and parallel in front of the body with the eyes closed resulted in a very slight spontaneous deviation of the right hand to the right and the spontaneous movements of the left arm and hand.

The sphincters were normal. The abdomen was full and the anterior abdominal wall rather lax. The bowels were normal. The heart and peripheral vessels were normal but the retinal arteries were arterio-sclerotic. The pulse was regular; the blood pressure was 160 systolic and 115 diastolic. The patient had a frequent, loose cough; there were sonorous rhonchi over the right lower chest behind, and fine crepitations were audible at both bases. The skull and spine were normal.

The cerebro-spinal fluid obtained by lumbar puncture was clear and contained five "small lymphocytes" per c.mm. There was 0·24 per cent. of total protein. Globulin was present in very marked excess, mostly pseudo-globulin, with the faintest trace of fibrinogen and a trace of euglobulin. Free complement was present. The Wassermann reaction was completely negative with the heated fluid. The Lange test produced the curve: 2346444443. The Wassermann reaction in the blood was negative.

Attention could be gained but not maintained for any length of time; perception and orientation were normal; the memory was defective, and the reasoning power was apparently unaffected. On account of the difficulty in keeping the patient's attention, those parts of the clinical examination dependent upon her coöperation were difficult to carry out.

Subsequent Progress.

Dec. 14th, 1928.—All types of sensation were impaired in both the upper and lower limbs and the patient's coöperation and attention were not so good as they had been at the previous examination. The changes were more advanced in the left arm and had appeared in the right arm as well. In the left arm motive power was practically absent, the limb was flaccid and definite movement towards an object was impossible. An attempt to test the rebound of the limb resulted in its falling like a flail. In the right arm motor power was very poor, muscle tone was decreased, and there was definite intention tremor. Rebound was very poor, while dysmetria and decomposition of movements was quite evident. In the left leg motor power was very poor, the limb was flaccid, the knee-jerk was absent, and there was no response on stimulation of the sole of the foot. In the right leg the same changes were evident, except that the loss of tone was not so pronounced. The right pupil was larger than the left, and both reacted sluggishly to light.

Dec. 31st.—The patient had a respiratory infection with a febrile reaction and rhonchi over the whole of the chest. The heart sounds were strong. The condition of the left arm was unchanged, but the right arm had become almost as hypotonic as the left, with pronounced flaccidity, absence of deep reflexes, dysmetria, decomposition of movements, and absence of rebound. There was complete inability to retain either the right or the left arm in one position. The left leg was unchanged, but in the right leg hypotonia was more pronounced. On both sides an attempt to elicit the plantar reflex produced no response. Spontaneous movements were present in both the right and the left arm when movements of the limbs were commenced voluntarily. Local muscle "twitchings" were present in all four limbs. A chart of the visual fields showed moderate concentric contraction of both fields.

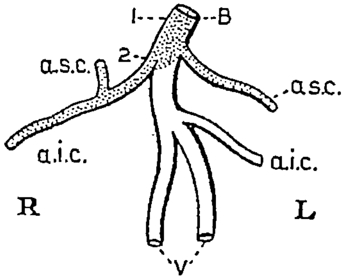
Jan. 1st, 1929.—There were numerous crepitations at both bases.

Jan. 2nd.—The right base was dull on percussion, there were numerous bubbling râles over the whole of the back of the chest, and the heart sounds were failing. Death occurred the following day.

The Pathological Findings.

The autopsy was confined to the brain. There was no evidence of any gross lesion on naked-eye examination. The arteries at the base was examined in detail and found to vary somewhat from the usual anatomical arrangement.

(See figure.) After giving off the posterior inferior cerebellar arteries, the two vertebral arteries united to form the basilar artery at the lower border of the pons. A little above this level a small branch, probably the anterior inferior cerebellar artery, was given off on the left side and distributed to the anterior portion of the inferior surface of the left lateral lobe of the cerebellum. Slightly below the middle of the pons there was a large branch on the right side which immediately divided into two branches, the lower representing the anterior inferior cerebellar artery and the upper the superior cerebellar artery. At the middle of the pons a large branch was given off on the left side—the left superior cerebellar artery. The lumen of the vertebral arteries, the posterior inferior cerebellar arteries, the left anterior inferior cerebellar artery, and the basilar artery as far as the large branch on the right side was quite patent. From the large branch on the right side up to the posterior communicating branches the basilar artery was definitely thrombosed. This thrombus extended into the common stem of the superior cerebellar and anterior inferior cerebellar arteries on the right side and into the superior cerebellar artery on the left. No naked-eye changes were visible in the area of distribution of these vessels.



Diagrammatic representation of the arteries at the base of the brain in the case described. The vertebral arteries (V) unite to form the basilar artery (B) and at once give off the anterior inferior cerebellar artery (A.I.C.) on the *left* side. Above this level and slightly below the middle of the pons, on the *right* side, there arises from the basilar artery a large branch which immediately divides into two branches—the lower (A.I.C.) representing the right anterior inferior cerebellar artery and the upper (A.S.C.) the right superior cerebellar artery. At the middle of the pons a further branch is given off on the left side—viz., the left superior cerebellar artery. The shaded area represents thrombosis. 1 = Recent red thrombus with (microscopically) great excess of leucocytes. 2 = Recent thrombus slightly adherent to vessel wall with more fibrin than 1, and some endarteritis proliferans of inner coat.

Sections of the basilar artery were made (1) midway between the left superior cerebellar artery and the posterior communicating branches; (2) at its junction with the left superior cerebellar artery; and (3) at its junction with the common stem of the right superior cerebellar and anterior inferior cerebellar arteries. Microscopical examination of the first section showed the presence of recent red thrombus with a great excess of leucocytes, both polymorphonuclear and mononuclear cells. The second section showed similar changes, but a little more fibrin was present; the clot was slightly adherent to the wall of the vessel and there was some endarteritis proliferans of the inner coat. The third section was similar to the second, the latter including the left superior cerebellar artery and the former the common stem of the right superior cerebellar artery and anterior inferior cerebellar artery.

Vertical antero-posterior sections were made through the lateral lobes of the cerebellum close to the pons. The sections were examined particularly for evidence of degenerative changes and of any obvious differences between the two sides. Nothing very striking could be made out either in the molecular or the granular layers, excepting perhaps some degenerative rarefaction at the junction of these parts where the Purkinje cells lie, though probably some of this appearance was merely an artefact. In the white matter of both sides of the upper half of the cerebellum there were, however, some small scattered areas of glial rarefaction—"froth-like areas"—probably around or in the neighbourhood of blocked or degenerated vessels, a few of them almost amounting to small degeneration pseudo-cysts. Occasional vessels showed some perivascular "small round-cell" collections, and many had dilated lymphoid spaces around them. Some thrombosis of small vessels was also present in the lower part of the superior cerebellar peduncles and in the lateral parts of the pons.

Commentary.

When the patient came under observation there was probably a number of small thromboses in different parts of the brain, as suggested by the decrease in the patient's mental acuity. The physical signs elicited at that stage would appear to have been due to two distinct groups of thromboses. The spontaneous movements, loss of muscle tone, and the associated changes in the left arm were probably the result of thrombosis of the left superior cerebellar artery, while the sensory changes on the same side were probably the result of thromboses already present in the small pontine branches of the basilar artery on the right side. It appears to be unnecessary to assume that the motor changes and the variations in sensation were the result of the thrombosis of a single artery in a patient in whom there was some evidence of multiple thromboses elsewhere. Such, however, would appear to be the assumption made by Guillain, Bertrand, and Peron in their description of a case of thrombosis of the superior cerebellar artery and identification of the syndrome of the superior cerebellar artery. In their case the three important groups of symptoms were: (1) involuntary movements of the right side and particularly of the arm; (2) a right-sided hemi-cerebellar complex; and (3) left-sided dissociated hemi-anæsthesia of the syringomyelic type. Associated with these symptoms was softening of the superior aspect of the right cerebellar hemisphere and of the lateral aspect of the right side of the pons; disintegration of the right superior cerebellar peduncle and lateral fillet, and no involvement of either the pyramidal system or any of the cranial nerves. It is difficult to see why the entire clinical and pathological picture in this case was included as the syndrome of thrombosis of the superior cerebellar artery. It is more probable that the symptoms and pathological changes referable to the lateral part of the pons were due to thrombosis of the small pontine branches of the basilar artery on that side, and that the symptoms and pathological changes referable to the cerebellum and superior cerebellar peduncle were the result of thrombosis of the superior cerebellar artery on that side. If that were so, the pontine symptoms would have been comparable to those which appear when the lateral arteries of the medulla become thrombosed. The clinical and pathological findings in our case support the view that the clinical picture in Guillain, Bertrand, and Peron's case[1] was the result of two distinct groups of thromboses, for in our case it is impossible to explain the occurrence of sensory changes and cerebellar signs on the same side by postulating that the superior cerebellar artery supplies the lateral aspect of the pons as well as the superior surface of the cerebellum and the superior cerebellar peduncles.

We suggest, therefore, that the syndrome of thrombosis of the superior cerebellar artery might more correctly be defined as: (1) involuntary movements, particularly of the arm on the side of the lesion, together with (2) symptoms of a unilateral cerebellar lesion on the same side. The movements are wavy and sinuous with a definite, slow pattern, failing to reach an object if directed towards it, absent at rest, but appearing and aggravated by attempts at movement or by emotion. The symptoms of a unilateral cerebellar lesion present are those usually associated with such a lesion, but the loss of muscle tone is the most prominent feature. The symptoms are also much more definite in the arm than in the leg.

The pathological changes underlying the subsequent clinical picture in our patient were probably thrombosis of the pontine branches of the basilar artery on the left side as well as on the right, thrombosis of the basilar artery itself and occlusion of the common stem of the superior cerebellar and anterior inferior cerebellar arteries on the right side. The constriction of the visual fields was probably due to interference with the blood-supply to the visual cortex by way of the posterior cerebral arteries; this interference was only partial, partly because of the incomplete occlusion of the vessel and partly because of the anastomotic supply to the visual cortex, particularly to the area for macular vision, through the middle cerebral artery.

It is interesting to note that the so-called syndrome of the superior cerebellar artery was much more extensive on the right side than on the left, in that the leg was affected quite as seriously as the arm. This was due to the unusual anatomical arrangement on the right side—the superior cerebellar and the anterior inferior cerebellar arteries arising from the basilar artery by a common stem. Consequently thrombosis of the stem and of its two branches resulted in interference with the blood-supply of part of the inferior surface of the cerebellum as well as of the superior surface. The difference in the clinical pictures on the two sides strongly supports the localisation of the control of movements of the upper limbs in the upper part of the cerebellum, and of those of the lower limbs in the lower part of the cerebellum.

---

[1] Guillain, G., Bertrand, I., and Peron, N.: Rev. Neurol., 1928, ii., 835.

The changes in the cerebro-spinal fluid were unusual and resembled those seen in cases of spinal block. Free complement was present in the fluid, and in the Lange test there was maximum decolorisation of the gold solution in the middle of the series of dilutions. These changes, so common in cases of spinal block, appear to be equally characteristic of cases of cerebral thrombosis in which it is probable that there is some encroachment of the thrombotic areas on the cerebro-spinal fluid system.

We are greatly indebted to Dr. W. E. Carnegie Dickson for the pathological report.

Summary and Conclusions.

1. A detailed description is given of a case of cerebral thrombosis in which the prominent early lesion was thrombosis of the left superior cerebellar artery.
2. The syndrome of thrombosis of the superior cerebellar artery includes spontaneous movements on the side affected, together with the symptoms and signs of a unilateral lesion of the cerebellum on the same side.
3. There appears to be no justification for including the sensory changes frequently present as a part of the syndrome of occlusion of the superior cerebellar artery; they are much more satisfactorily explained as the result of other thromboses in the small pontine branches of the basilar artery.
4. When the superior cerebellar artery arises alone from the basilar artery the clinical picture of thrombosis of the vessel is that described above and involves chiefly the arm; when, however, this vessel arises by a stem common to it and to the anterior inferior cerebellar artery, occlusion of this stem produces changes in the affected leg almost as definite as those in the affected arm.
5. The changes in the cerebro-spinal fluid are similar to those occurring in cases of spinal block; they are probably the result of encroachment of thrombotic areas on the cerebro-spinal fluid system.

AURICULAR FIBRILLATION IN CHILDREN.

BY HAROLD COOKSON,* M.D., B.Sc., M.R.C.P. LOND.

(From the Cardiographic Department, London Hospital.)

IT is well known that complete arrhythmia is uncommon in children. In the tables of the age-incidence of the disorder which have been published relatively few cases under 20 years occur. Levine found none under 17 out of 128; Brachmann found none under 10, and eight only between 10 and 20, out of 400; Willius had five cases between 11 and 20, out of 500; Mackenzie records five cases under 20, out of 500; Cowan and Ritchie had six between 10 and 19, out of 300; Coombs in 58 cases of rheumatic heart disease had two between 11 and 20; Hart found one under 10 in 300.

In the first decade auricular fibrillation has occurred so rarely that the published records nearly all deal with isolated examples. It has been recorded that fibrillation developed in a child of 3 (Samet and Tezner); digitalis was being given but the authors deny any connexion between the medication and the arrhythmia. No graphic record is published, however, in support of the claim, and as fibrillation is otherwise unknown at this age, the case cannot be accepted as authentic. Resnik and Scott publish the case of a boy of 4 with auricular fibrillation; the ætiology is uncertain, but is probably rheumatic. This is the youngest case in which graphic proof is supplied. Leys and Russell recorded the case of a boy of 6 who came under observation with a large heart. At first there were three distinct rhythms—probably auricular flutter, auricular fibrillation, and normal rhythm—but since then, a period of two years, fibrillation has been present, and the child has had to be kept in bed most of the time on account of cardiac and acute rheumatic symptoms (personal communication). Other solitary cases are reported by Ogden, Ehrenreich, Nobecourt and Pichon, and Sidel and Dorwart. A case recorded by Nadel is quoted by Schwartz and Weiss as an example of fibrillation in a child of 10 or under, but the description of the electrocardiogram, which is not itself published, suggests flutter. Moreover, the child was 11 when the abnormal rhythm was first observed. In the case described by Sutherland and Coombs, the polygram, as Schwartz and Weiss also note, is more suggestive of premature beats than fibrillation. Again, in that of Price and Ivy Mackenzie, said to show fibrillation and complete block, the tracing published leaves the diagnosis of fibrillation uncertain. Neuhof cites the case of a child of 8 whose electrocardiogram is said to show a short paroxysm of fibrillation lasting about three seconds; it is difficult, however, to exclude an instrumental cause for the oscillations which have been taken to indicate fibrillation in this record. In Coombs's series of rheumatic cases with fibrillation there are two under 10, but no details are given. In these 11 reported cases, aged 10 or less, rheumatic heart disease was certainly present in six and probably present in two others. In three of the cases in which the arrhythmia was permanent, death occurred on the average seven months after it was discovered. One patient is still alive two years after the inception of fibrillation, though confined to bed.

Recently Schwartz and Weiss have asserted that fibrillation in children is not nearly so rare as has been supposed. They recorded it with the electrocardiograph in 10 out of 60 patients admitted to hospital with rheumatic heart disease in a period of five and a half years. Six were aged 7½ to 10, and four 11 to 15. Four of their cases died within a week of the onset, and three more within a year. The authors believe that the unusually high incidence of auricular fibrillation in their cases was the result of more careful observation and, as evidence in support of this, they quote the incidence—a much lower one—for a previous period in their hospital. Another factor must be considered, however, and that is the quantity of digitalis which their patients received; in the instances in which the dose is stated, the amounts usually exceed those which in this country would be considered adequate for an adult. All were having digitalis at the time of onset of the arrhythmia. In discussing the causation of the arrhythmia in their cases Schwartz and Weiss consider digitalis as a factor, but only in one case do they regard it as being definitely related to the onset; in the others they regard the relationship as unproved. It remains quite likely, however, that digitalis is the explanation of the high incidence of fibrillation which they discover in children. There is no lack of evidence, both experimental and clinical, that digitalis is able to produce auricular fibrillation. (See Danielopolu, Mackenzie, Reid, and Resnik.)

Thirty-five Cases of Auricular Fibrillation in Children.

In 15 years (1913–28) auricular fibrillation was diagnosed in 1164 cases admitted to the London Hospital; females were twice as numerous as males.

---

* Working under the Paterson Bequest.

Those of 17 and under have for the purpose of this investigation been considered as "children." There were 30 "child" cases, or 2·5 per cent.; five have been added from other sources making 35 in all; the sex ratio was three girls to two boys—a smaller female predominance than in the adults. The youngest was aged 12. The diagnosis of fibrillation rests on graphic proof in only 10 cases—an unfortunate fact, due largely to the present reliability of clinical methods which are satisfactory for any but research purposes, and partly to the serious condition of some of the patients, which did not justify interference for non-essential examinations. Where graphic records are lacking the other findings are as conclusive as possible, and in all the following criteria are satisfied: rapid and very irregular heart, persistent irregularity, and response to digitalis by considerable slowing. Rheumatic heart disease was the basis of the arrhythmia in all cases, and a history of the acute illness was lacking in six only. The average age at which the first rheumatic symptom showed itself was not unusually early, though a majority of the cases had suffered from symptoms of heart disease for a considerable period before the onset of the irregular rhythm; in 19 cases this period averaged four and a half years; in four cardiac symptoms appeared for the first time with the onset of fibrillation. As is the rule in adults, failure was a familiar accompaniment of the inception of the new rhythm and occurred in 22 out of 30 in which satisfactory information on this point could be obtained. In five failure had made its appearance while normal rhythm was present, and in the remaining three no failure was observed immediately or shortly after the onset.

Clinically, mitral stenosis was diagnosed in 25 of the 35 cases, four of these having aortic incompetence in addition; in two the aortic valve alone was affected. The heart was enlarged to palpation in all, considerably so in 17 (48 per cent.). Thirty-one cases have now been traced, and of these 23 have died of heart disease after an average duration of ten months with auricular fibrillation, the maximum period being five years and the minimum three weeks. It is interesting to note the fate of three patients in whom reversion to normal rhythm took place after short periods of fibrillation. In one in whom the reversion was spontaneous death occurred five years afterwards from meningitis, normal rhythm persisting till the end. Another, a boy of 16 successfully treated with quinidine, is alive and has normal rhythm six and a half years later, and is able to do light work. The third case merits, perhaps, a description in more detail.

In 1913 a girl, aged 17, was admitted to hospital with mitral stenosis, auricular fibrillation, and failure, the onset of which coincided with that of the abnormal rhythm. Treatment with rest and digitalis gave some relief but she was still very ill at the time of her discharge and the parents were told that she would be unable to do any work. In 1929, 16 years later, she reported at the hospital with normal rhythm. The heart was considerably enlarged, and the signs of mitral stenosis and aortic incompetence were present. She was in fairly good health, and said that from a time six months after her discharge from hospital she had been doing office work, and her only enforced absence from this had been a period of two weeks with "influenza." Moreover, she was able to dance and to play tennis for an hour at a stretch. It is impossible to date the return to normal rhythm in this case, but it probably happened soon after she left hospital as she has never since felt the heart beating rapidly as it did then.

The subsequent duration of life in these three instances of return to normal rhythm forms a contrast with the expectation of life in those with persistent fibrillation, which may not be without significance.

Established fibrillation in young people of 17 and wher must be regarded as a serious condition which probabl long survived. In 23 cases the average duration parts of after the onset of the abnormal rhythm was patient's ths. During those months the patients were at that stage wo with congestive heart failure on which distinct groups is had little effect. This is in contrast movements, loss oonding condition in adults, in whom the average duration of life is much longer (four and a quarter years in a group of 47 rheumatic cases followed up till death),† and appropriate treatment commonly gives rapid relief. No other cause than rheumatic heart disease was found to account for fibrillation in children. It was not found that rheumatic fever had affected the patients at an earlier age than usual, but a history of suffering from heart disease for several years before the onset of the arrhythmia was the rule, although severe symptoms and the signs of congestive failure only appear, in the majority, when the change in rhythm occurs.

I have to thank Dr. John Parkinson for his help and those physicians of the London Hospital who have permitted me to use their cases.

GLUCOSE INTOLERANCE IN VARIOUS DERMATOSES.

BY ALEX. R. SOMERFORD, M.B. MANCH.,

ASSISTANT MEDICAL OFFICER, MANCHESTER ROYAL INFIRMARY; MEDICAL REGISTRAR, MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.

SINCE 1915, when Pels published his results of an investigation of the blood-sugar content of 50 cases of various dermatoses, several papers have been written on the subject, but, although all the investigators agree that a slight hyperglycæmia occurs, the type of lesion in which the rise is present varies in the different papers.

Pels [1] found the blood-sugar varied from 0·07 to 0·156 per cent., the average being 0·107. These readings showed hardly any increase above the normal, but were approaching the higher limit of normality. He suggested that further research would elucidate the types of lesion in which an alimentary hyperglycæmia could be inferred, and that the treatment of hyperglycæmia would be a useful aid in the treatment of skin diseases.

In 1916, Highman, Schwartz, and Mahnken [2] investigated 149 cases, 89 of which gave no increase, but a group of 60 cases of acne, seborrhœa, and sycosis gave a more or less constant hyperglycæmia. They considered that lesions of the pilosebaceous follicles were more liable to be associated with hyperglycæmia. In 1921, Pick [3] reported an almost constantly increased blood-sugar content in cases of psoriasis, a slight increase in the majority of seven cases of furunculosis, and a moderate hyperglycæmia in six of 12 cases of secondary syphilis. McGlasson[4] investigated a large series of cases but only took one reading of each patient. He did not think that the hyperglycæmia was the only ætiological factor but noted a definite sensitiveness in some cases, and that the hyperglycæmia was higher at each recurrence of the disease. He found a marked improvement in the skin lesion when the patients were given a carbohydrate restricted diet.

---

† Unpublished observations.

In England Haldin-Davis, working with Willis,[5] found a definite abnormality in 13 out of 20 cases of eczema but was unable to correlate abnormalities in blood-sugar with any particular type of eczema. He found that diabetic treatment was unsatisfactory. Campbell and Burgess[6] divided skin lesions associated with hyperglycæmia into two groups—namely, those occurring during pregnancy and those developing in patients over 50 years of age. They reported good results following suitable dieting, and pointed out that there is nothing to suggest sugar intolerance in the appearance of a lesion, but that it should be suspected where an intractable dermatitis develops in a person of middle age who was previously quite free.

The Present Investigation.

This paper embodies the result of personal investigation of 120 cases at the Manchester and Salford Hospital for Skin Diseases.

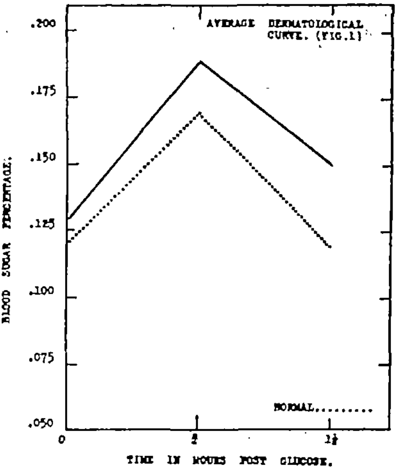
A fasting reading was taken in each case; 50 g. of glucose in 150 c.cm. of water were then given by the mouth and further readings taken three-quarters and one and a half hours later. The normal blood-sugar varies considerably in healthy subjects, so the average for a series rather than individual results have been taken wherever possible, and the highest limits of normality have been taken as 0·12 per cent. for the *fasting level and 0·17 for the maximal reading.*

Of 120 cases of all types of dermatoses only 28 (23·3 per cent.) gave normal sugar readings. The other 92 showed some deviation from the normal, though in many cases the abnormality was only slight. The average curve for the series was a fasting level of 0·13 rising to 0·188 three-quarters of an hour after the ingestion of glucose, and decreasing to 0·15 in another 45 minutes (Fig. 1). From these results it will be seen that a large percentage (76·7) of patients suffering from dermatological lesions show some abnormality in their blood-sugar content. Furthermore, the abnormality is in most cases of the "lag" type, an abnormality which points to some defect in the mechanism by which glucose is stored in the liver as glycogen.

The question next to be considered is the type of lesion in which a hyperglycæmia is liable to occur. To ascertain this a pathological classification was first adopted.

In psoriasis, of which 14 cases were examined, the average blood-sugar curve was raised throughout to a slight extent, rising from a fasting level of 0·13 to 0·19 per cent. in the second reading and falling to 0·16 in the last reading. In the lichen group—a group of diseases characterised by intense itching—the curve was higher throughout, rising from 0·151 to 0·207 and falling to 0·177. In nine cases of pruritus—localised and general—in which no cause for the pruritus could be discovered and which were, therefore, classified as pruritus simplex, the curve rose from 0·134 to 0·206, falling to 0·141 in an hour and a half. Forty cases of eczema showed on the average a very slight increase but some delayed lysis, the three estimations reading 0·131, 0·191, and 0·148. A group of 20 cases of disease of the pilosebaceous follicles, such as acne vulgaris and coccogenic sycosis, gave readings 0·121, 0·173, and 0·130, showing practically no increase at all.

From these figures it will be seen that a slight increase occurred in each group, but a much more marked increase was present in the lichen and pruritic groups. The statement of Highman, Schwartz, and Mahnken that diseases of the pilosebaceous follicles showed the most marked hyperglycæmia was not confirmed. In fact this group of cases showed the least deviation from normal of the whole series. Pathological classification did not point to any one lesion being associated with glucose intolerance. The lesions showing the greatest deviation from the normal—namely, the lichen and pruritic groups—had a common symptom in itching which is most marked in both conditions. It was, therefore, thought desirable to investigate the association of hyperglycæmia with itching.



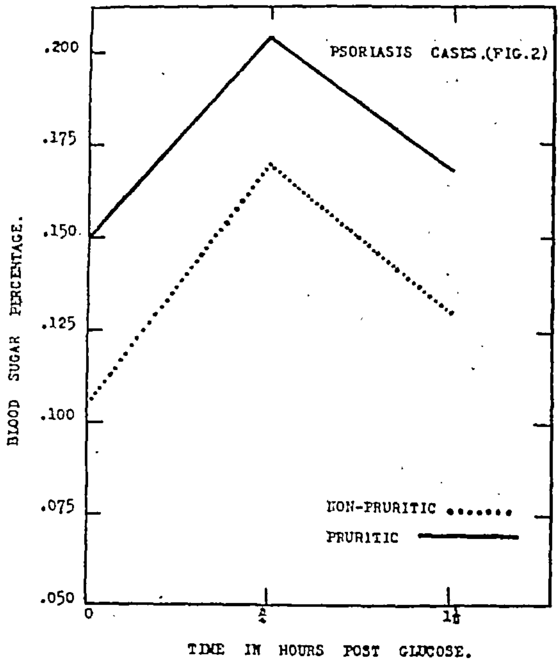
Symptomatic Classification.

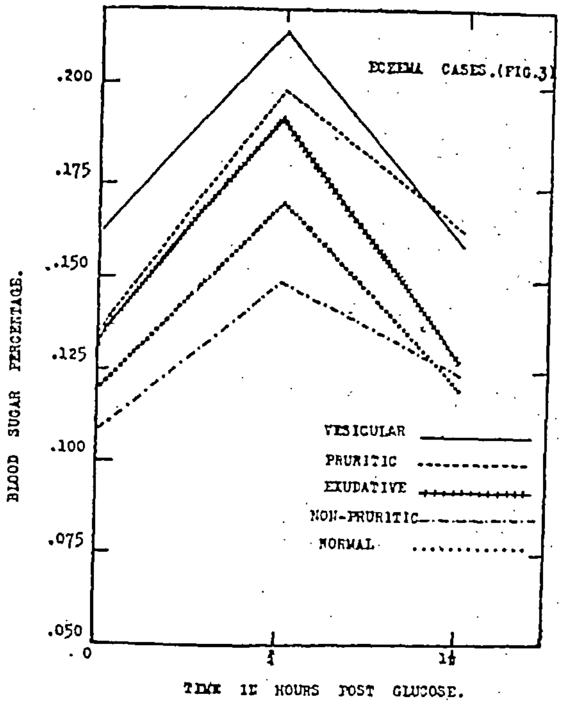
In considering the relation of pruritus to the presence of hyperglycæmia it is useful to have a lesion of definite pathology and clinical appearance in which pruritus is variable. Such a lesion is psoriasis vulgaris, which is a chronic inflammatory disease of the skin characterised by scaliness but in which there is no exudation.

In my series of psoriatic patients the disease was, to all appearances, identical in all the cases. Actively erupting lesions were not tested, since pruritus is present in this form more or less constantly, but in cases of some weeks' duration pruritus is sometimes present, sometimes absent. The cases chosen were clinically in the same stage of the disease—that is, they were of some weeks' duration and the surface of the skin had not been made sore by the application of strong ointments. Eight out of 14 of these cases were associated with pruritus and gave an average curve of 0·151, 0·204, and 0·169 per cent., while the remaining six cases in which pruritus was absent gave a much lower reading of 0·104, 0·17, and 0·13 (Fig. 2).

In the cases of the eczematous group the problem presented more difficulties since the term eczema covers a number of lesions which vary considerably in clinical features. The cases were divided, therefore, into four classes according to the clinical stages of the disease. The first stage consists of an erythema without abrasion of the surface and accompanied by intense pruritus, which is termed the pruritic type of eczema. This may progress to the formation of papules which later become vesicles; pruritus is still intense; this is termed the vesicular type. One or two changes may now take place; either the vesicles become broken giving rise to a "weeping" eczema, or the skin may resolve into a dry, hardened, non-pruritic condition. These types are termed respectively the exudative and the dry non-pruritic type.

In examining the average curves given by these four subdivisions it was found that the vesicular type gave the highest reading with the pruritic type slightly lower in the first two readings and slightly higher in the third reading. The exudative type came next with readings higher than normal, and the dry non-pruritic type lowest, with a response to glucose less than the maximal normal (Fig. 3).





Type of eczema.	Pruritus.	Fasting.	Blood-sugar estimation per cent.	
			¾ hr. post-glucose.	1½ hrs. post-glucose.
Vesicular ..	Present.	0·162	0·217	0·158
Pruritic ..	,,	0·136	0·202	0·163
Exudative ..	Absent.	0·122	0·193	0·127
Dry non-pruritic	,,	0·108	0·148	0·124

The values below normal of the dry non-pruritic type are of interest and suggest a response on the part of the organism to the raised blood-sugar content present in the earlier stages of the disease.

In eczema, therefore, it appears that pruritus and the occurrence of any hyperglycæmia are directly related. In addition, however, the presence of an epidermal exudate is also associated with hyperglycæmia for so long as the exudate is retained in the tissues, but, when the exudate escapes externally, as in "weeping" eczema, the pruritus ceases and the hyperglycæmia disappears. This suggests absorption of the epidermal secretion as a cause of the hyperglycæmia.

In addition, 58 out of 67 (86·6 per cent.) patients who complained of itching showed some intolerance to glucose.

Discussion.

McGlasson found a hyperglycæmia associated with pruritus and the present results confirm this. It is, however, impossible to state dogmatically that hyperglycæmia will or will not be present in any given case.

Previous writers suggest that the hyperglycæmia points to the patients being potential diabetics. Many of the cases in this series were under observation for two or more years, and in no case was a true diabetes or even glycosuria noted; in addition only a few diabetic patients give a history of previous skin trouble. There seems to be no definite evidence, therefore, for the assumption that these patients are potential diabetics.

In America, restriction of carbohydrate in the diet has given good therapeutic results in cases associated with hyperglycæmia. In our hands dietetic treatment has not been satisfactory although restriction of carbohydrate diet does lessen the pruritus in many cases. Some writers have found carbohydrate restriction of use in the treatment of acne vulgaris; this has not been our experience, as might be expected from the fact that such lesions do not show any marked abnormality in carbohydrate metabolism. Whether we should regard the hyperglycæmia as an ætiological factor or as a concomitant condition is the subject of further research.

In conclusion, I should like to express my indebtedness to Drs. G. H. Lancashire, Louis Savatard, and R. Gibson for allowing me the use of their cases, and to Dr. William Dyson, who has given much useful criticism and advice in the preparation of this paper.

A "UNIVERSITY WARD" AT NOTTINGHAM.—Seven beds in Nottingham General Hospital have already been endowed with money raised by the students of the city's University College, and progress is being made towards the provision of an eighth. The students are ambitious of eventually endowing a complete ward of 20 beds, and it has been arranged that it shall be called "University Ward." The hospital has now received £20,000 on account of this year's Hospital Saturday Fund.

Clinical and Laboratory Notes.

THE ISOLATION OF *BRUCELLA ABORTUS* FROM A CASE OF UNDULANT FEVER.

By H. J. NIGHTINGALE, M.S. LOND., F.R.C.S. ENG.,
HON. SURGEON TO THE ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL;

AND

G. S. WILSON, M.D., M.R.C.P. LOND., D.P.H.,
READER IN BACTERIOLOGY AND IMMUNOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Dalrymple-Champneys[1] has collected records of 14 well-authenticated cases of undulant fever originating in England. Recently another case has been reported by Bloxsome and Davey.[2] The diagnosis of these cases has rested on the agglutination of *Brucella abortus* by the patient's serum. The following case is remarkable for the isolation of *Br. abortus* in pure culture from the blood.

Clinical Report by MR. NIGHTINGALE.

The patient, Mrs. B., came under notice first on May 20th, 1929, with slight pyrexia of about 100–101° F. No symptoms beyond a little malaise were complained of. Between April 17th and May 6th she had spent a holiday on the continent, visiting Belgium, Germany, Austria, and Switzerland, the last week being spent in Switzerland.

In view of our ignorance of the incubation period of this disease it is impossible to say whether she contracted her infection abroad or shortly after her return to this country. There is likewise no evidence to indicate how infection occurred; she dislikes raw milk, and takes it only in tea or coffee.

Throughout the whole pyrexial period, lasting for some 13 weeks, there was a striking absence of symptoms and physical signs. The patient never looked ill and lost neither weight nor colour. The pulse-rate never rose above 70–80. When the temperature was at its greatest height she had a feeling of nausea and a great distaste for food, but beyond that there was nothing to note. There was no sweating and no pain.

The blood was tested for a Widal reaction early in the illness and proved negative. On July 12th a sample was sent to Dr. Knyvett Gordon at the Virol Laboratories, and he reported it as giving a negative Widal reaction to all the typhoid-paratyphoid group but as agglutinating *Br. abortus* in a dilution of 1/400. A further test on July 24th made by Dr. Wilson gave agglutination to *Br. abortus* in a dilution of 1/1280. Recovery, though tedious and slow, was complete, and the patient at the end of October was in full normal health. It may be said briefly that no form of medicinal treatment seemed to have the slightest effect on the course of the illness.

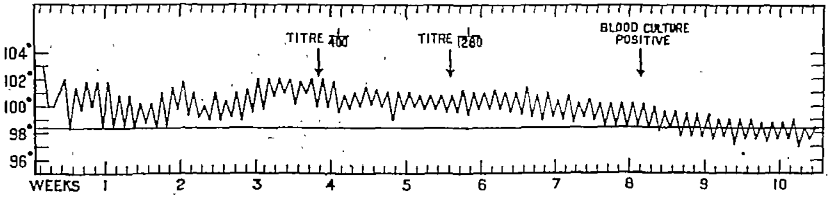
The accompanying chart, which was not commenced for three weeks after the onset of the illness, illustrates the undulant character of the fever, and the very gradual fall to normal.

Bacteriological Report by DR. WILSON.

The patient's blood was collected on August 11th at about the beginning of the twelfth week of illness; 5 c.cm. were taken by Mr. Nightingale into a tube of glucose broth which was sealed with a special rubber cap and despatched by post.

On the next day the blood-broth mixture was distributed as follows: (1) 1 c.cm. into flask A, containing 50 c.cm. of Huddleson's liver extract[3] broth, pH 6·6; (2) 5 c.cm. into flask B, containing the same medium; and (3) 5 c.cm. into flask C, containing 500 c.cm. of glycerol broth, pH 7·2. The three flasks were put in a modified McIntosh and Fildes's jar, and 5 per cent. of the air in the jar was replaced by CO_2 from a cylinder. After incubation at 37° C. for four days the cultures were inoculated on to agar and glycerol agar slopes, which were incubated in 5 per cent. CO_2. As no growth occurred after five days these subcultures were discarded. A second series of subcultures were made from the flasks on the seventh day, using agar slopes only; one set of slopes were incubated in 5 per cent. CO_2, and one set were fitted with paraffined corks.

Two days later the agar slopes inoculated from flasks A and B, and incubated in 5 per cent. CO_2, showed discrete, circular, convex, translucent, greyish-yellow colonies, having a diameter of 0·2–1·5 mm. Microscopically these consisted of small Gram-negative cocco-bacilli, 0·8–1·3 μ long and 0·4 μ broad. Similar colonies appeared after five days in the sealed tubes inoculated from flasks A and B. The tubes inoculated from flask C remained permanently sterile; but in a third series of subcultures on to agar slopes, made after the flasks had been incubated for nine days, growth was obtained from all three flasks.



Temperature chart in a case of *Br. abortus* infection.

The organism that was recovered from the patient's blood was identified as *Br. abortus* for the following reasons. Besides having the typical morphological and colonial characters of this organism, it failed to ferment any of the usual sugars, it rendered litmus milk alkaline, it produced a small amount of ammonia from peptone water, and it blackened lead acetate medium in three days. For the first two or three subcultures it refused to grow aerobically, though it grew in sealed tubes in four or five days, and in 5 per cent. CO_2 in two days. Inoculated intramuscularly or intraperitoneally into guinea-pigs in a dose of about 500–1000 million organisms, it gave rise to no obvious illness; when the animals were killed after four to eight weeks the spleen was slightly enlarged and was covered with tiny greyish gelatinous nodules, projecting slightly or not at all above the surface; in two animals inoculated intramuscularly into the thigh the sublumbar glands were slightly enlarged; in the animal inoculated intraperitoneally two or three mesenteric glands were enlarged, and the testes were acutely congested. A serum prepared against the patient's strain agglutinated to titre a number of *Br. abortus* strains that were recovered from milk in this country by Wilson and Nutt in 1926.[4] Cross-absorption tests put up between the patient's strain and one of the bovine strains, using the sera prepared against these two strains, showed that both organisms were able to remove all agglutinins from both sera.

Four strains, reputed to be *Br. melitensis*, were available for testing; of these only two could be regarded with certainty as belonging to this species. Neither of these two known strains, nor a third strain, whose history was unknown, were agglutinated to titre by the patient's serum, nor were they able to absorb completely the agglutinins from this serum. The fourth strain, whose history was unknown, appeared to be antigenically identical with the patient's organism. A strain of *Br. abortus* of porcine origin, tested against the patient's serum, was agglutinated to only ¼ titre, and was unable to remove more than about 75 per cent. of the agglutinins.

---

[1] Dalrymple-Champneys, W.: Report on Public Health and Medical Subjects, No. 56. H.M. Stationery Office. 1929.

[2] Bloxsome, H. E., and Davey, E. N.: THE LANCET, Oct. 19th, p. 818.

[3] Huddleson, I. F., Hasley, D. E., and Torrey, J. P.: Jour. Infect. Dis., 1927, xl., 352.

[4] Wilson, G. S., and Nutt, M. M.: Jour. Path. and Bact., 1926, xxix., 141.

It appears, therefore, from its morphological, metabolic, and serological properties that the organism isolated from the patient belonged to the species *Br. abortus* rather than to the species *Br. melitensis*, and from its serological properties that it conformed to the bovine rather than to the porcine type of *Br. abortus*.

THE IMPORTANCE OF TRANSFUSION IN THE TREATMENT OF PERNICIOUS ANÆMIA.

BY ALEXANDER GOODALL, M.D., F.R.C.P. EDIN.,
PHYSICIAN-IN-ORDINARY TO THE ROYAL INFIRMARY OF EDINBURGH;

AND

A. M. CALDER, M.B. EDIN.,
LATE HOUSE PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

THE introduction of liver therapy has entirely altered the outlook in pernicious anæmia, and the great majority of cases make a satisfactory recovery. In a considerable number, however, liver therapy fails or death occurs before liver therapy could reasonably be expected to succeed. In such cases transfusion of blood may be of the utmost service, either in giving a stimulus to the bone-marrow that liver alone appears to be unable to give, or in keeping the patient alive until response to liver treatment occurs.

We subjoin notes of cases which illustrate these points, and call special attention to Case 1, in which a second transfusion seemed to save the patient's life after a single transfusion and intensive liver therapy had failed and the outlook seemed hopeless. Case 2 illustrates a further point which we have frequently noted in the treatment of pernicious anæmia. That is the hitch in progress which often occurs when the percentage of hæmoglobin has reached a figure in the neighbourhood of 60. This difficulty is surmounted by a temporary massive dosage of liver and liver extract, and some ingenuity may be required in making the requisite quantity of extract acceptable to the patient. In this connexion some of the liver extracts on the market are useless.

CASE 1.—Male, aged 55, gunpowder worker, was first seen as an out-patient on May 30th, 1929, complaining of breathlessness, weakness, and a sensation of numbness of the fingers of seven months' duration. He gave a history of glossitis five months before the onset of his present complaint. He was thin and had a distinct lemon-yellow tint in the skin. His pulse-rate was 90 and his blood pressure 100; hæmic murmurs were audible. Appetite was poor and a test-meal showed entire absence of free hydrochloric acid, and a profuse growth of streptococci was obtained from the meal. No lesion of the nervous system could be detected. Blood examination revealed changes typical of pernicious anæmia, a striking feature being anisocytosis. He was sent home to be treated by his own doctor and ordered half a pound of liver a day.

The patient was seen again on June 11th, 1929, obviously much worse, and was admitted to hospital. The pallor of his lips and conjunctivæ and the lemon-yellow tint in the skin were very pronounced. Examination of the blood showed 1·15 million red corpuscles with 23 per cent. of hæmoglobin and reticulocytes 1 per cent. He was put on a dose of liver extract equivalent to 1 lb. of liver daily, but gauged by enumeration of reticulocytes there was no response, and on June 10th the red corpuscles had fallen to 0·89 million with hæmoglobin 15 per cent. and reticulocytes 1 to 2 per cent.

It was decided to transfuse him. The donor was the patient's nephew and the citrate method was employed. One pint of blood and one pint of saline were given. The patient had a slight rigor 1¼ hours later with a maximum temperature of 100° F. During the next few days he suffered from gastro-enteritis and it was impossible to get him to take his full dose of liver extract. He steadily became worse. The reticulocyte count never exceeded 2 per cent. and the hæmoglobin fell to 12 per cent. on the 24th.

At this stage it was decided to transfuse him again. The same donor, the same method, and the same amount of blood and saline were used. One hour after the transfusion the patient had a severe rigor and the temperature reached 104°. On examining a film the day after transfusion the most striking feature was an invasion of nucleated reds, a feature which had been entirely absent up to this point. The reticulocytes rose steadily from 1–2 per cent. on the day of transfusion to 44 per cent. on June 28th, and then fell again to 2 per cent. on July 6th. The patient improved from the date of the second transfusion on extract equal to 1 lb. of liver per day. The following table shows the blood counts at different stages.

Date in 1929.	Red corpuscles in millions.	Hæmoglobin percentage.	Colour-index.	Leucocytes in thousands.	Reticulocytes per cent.	Notes.
May 30th.	1·04	35	1·1	2·8	—	Out-patient.
June 11th.	1·15	23	1·0	2·0	1–2	Admitted.
" 19th.	0·89	15	0·9	—	1–2	Transfused.
" 24th.	0·52	12	1·2	—	1–2	"
" 26th.	0·75	18	1·2	—	10	—
" 28th.	1·075	21	1·0	—	44	—
July 6th.	2·15	35	0·83	2·8	2	—
" 25th.	3·35	66	0·9	3·0	—	—
Aug. 26th.	4·8	90	0·9	6·2	—	Discharged.
Sept. 25th.	4·9	98	1·0	7·8	—	Out-patient.

CASE 2.—A married woman of 37 was admitted on June 10th, 1929, with a history of progressive anæmia with intermittent attacks of metrorrhagia and gastro-enteritis. On admission she was unconscious, with a heart-rate of 130, an imperceptible pulse, and a blood pressure too low to record. Blood examination revealed: red corpuscles 355,000, hæmoglobin 8 per cent., colour-index 1·14, leucocytes 1200, reticulocytes nil. She was immediately transfused. The citrate method was employed and two and three-quarter hours were occupied in passing one pint of blood and a pint of saline into the vein. During the transfusion she recovered consciousness and was able to talk in a confused manner. From the day of her transfusion she received liver extract equivalent to half a pound daily and steadily improved. The table shows the blood counts at various stages.

* Transfused.

The interesting feature is the fact that progress was arrested with the hæmoglobin at 62 per cent. When this occurred the dose of extract was doubled and raw liver added to the diet, after which the patient resumed her steady improvement and was discharged on August 19th, 1929, with 82 per cent. hæmoglobin.

CASE 3.—A married lady, aged 28, was seen by one of us in consultation with Dr. Fergus Hewat. She had become anæmic in the late stages of pregnancy and there was excessive bleeding at her confinement and some bleeding continued. The anæmia increased, and when seen three months later she was yellow, dyspnœic, distressed, and almost inarticulate. The red corpuscles numbered only 0·46 million. Megaloblasts were fairly numerous. The leucocytes were increase and included a few myelocytes. The diagnosis was pernicious anæmia complicated by hæmorrhage. As the condition seemed desperate an immediate transfusion was decided upon, and this was carried out by Mr. J. M. Graham. The result was most gratifying. Next day the anxiety and dyspnœa had gone and the patient was able to take liver extract. Films made four days after transfusion showed a remarkable picture of megaloblasts, many in mitosis, and some normoblasts with budding nuclei. For the last blood count we are indebted to Dr. Hewat, who tells us that the patient made a complete recovery.

Summary.

(1) Cases are recorded illustrating the importance of transfusion and, if necessary, of repeated transfusion in the severest examples of pernicious anæmia. (2) Progress in pernicious anæmia under liver therapy is often interrupted when the hæmoglobin percentage is in the neighbourhood of 60. This interruption may be tedious but can be overcome by massive doses of liver and liver extract. (3) It is important that only liver extracts of known activity should be used.

Medical Societies.

TUBERCULOSIS ASSOCIATION.

At a meeting of this Association held at the British Institute of Radiology, Welbeck-street, W., on Nov. 15th, a discussion took place on the ætiology and treatment of

SEROUS EFFUSION IN ARTIFICIAL PNEUMOTHORAX.

Dr. W. **Stobie**, opening the discussion on ætiology, said that the question presented many intricate problems, for the final elucidation of which a good deal more experience than he himself possessed was necessary, especially on the laboratory side. He had tackled the question from two aspects: from the point of view of the literature, and from his own personal experience. Many causes were adduced for the occurrence of serous effusion in artificial pneumothorax—the local anæsthetic, the cold air, too rapid filling, irritation of the gas, too much gas, pressure on the pulmonary vessels at the root of the lung, intercurrent affections, the introduction of minute portions of the tissues through which the needle has passed, over-exertion, menstruation, stage of the disease, injury of the visceral pleura, separation of adhesions, and so on. It was generally agreed, however, that age, sex, type of disease, or even the resistance of the patient, had little or nothing to do with the onset of an effusion. The speaker was convinced that the frequency of this complication was much greater than was generally believed, and was probably in the neighbourhood of 50 per cent. Many of these effusions could not be diagnosed without the help of the X rays. They should be on the look-out for a possible effusion when a slowing was noticed in the usual rate of absorption, or when on the manometer an unusually quick return occurred to the positive side. Among exponents of artificial pneumothorax there were extremely wide variations in technique, but there did appear to be one common factor—the separation of the pleural surfaces by the inflowing gas, whatever it might be. Moreover, in looking through a recent series of cases of his own, the one outstanding feature in those where fluid had developed was the presence of adhesions, generally in the upper part of the lung. It was more than likely that these adhesions were, as Dr. Gloyne had suggested, disease-bearing surfaces, which, undisturbed, were doing Nature's work of limiting the disease. Once they were stretched they were involved in the complication of hydrothorax. The stretching resulted as a rule from a combination of two closely allied forces—too large a volume of gas at too long an interval, especially a rapid jump from—e.g., 600 c.cm. to 1000 c.cm. after the lapse of several weeks. It was well to remind themselves from time to time that the original procedure in artificial pneumothorax was collapse of the lung and not compression—two very different things. The speaker also drew attention to the frequency with which fresh signs in the better lung or pleura had preceded the appearance of an effusion. Another point brought out was that the complication of serous effusion was more apt to occur in out-patients, who, freed from close medical care, were apt to take undue liberties in various directions.

The pathological examination of the fluid should theoretically give a good deal of help in determining the cause of an effusion in any given case. For example, where there was obvious extension of the disease the hydrothorax should be of the nature of an inflammatory exudate; while in the case of the compression of the vessels at the root of the lung the effusion should be of the passive transudate variety. The speaker hoped that in view of the importance of this side of the problem other speakers more competent to discuss it than himself would take it up.

Treatment.

Dr. F. G. **Chandler** followed with a paper on the treatment of pleural effusion in artificial pneumothorax. He pointed out that his remarks referred only to effusions of considerable size, since a small one, discoverable only by screening or a splash, he would always leave alone, unless there were some special reason for replacing it. Aspiration repeated two or three times frequently appeared to make the effusion thicken and become yellow. Moreover, even after the lung had been compressed for a long time by fluid it would re-expand, though it would often be smaller than formerly. The special reasons for interference included, in the speaker's opinion, the following:—

(1) If the effusion appeared to be producing a fever, after sufficient time had been allowed to give the pleurisy causing the effusion a chance of settling down.

(2) If in a case of moderate but progressive disease there was a fear, with a long-standing effusion, that the pleura would become so much thickened that the lung would never re-expand.

(3) If the effusion increased to such an extent that radiological control of the collapsed lung was no longer possible.

(4) If obliterative pleurisy was threatening.

(5) If a tuberculous empyema began to form, as evidenced by a thickening of the fluid and the appearance of large numbers of tubercle bacilli.

In group (4) replacement, though it might be tried, would probably prove ineffective and oil replacement should be undertaken. A complete oleothorax would not be necessary if the disease were in the upper part of the lung, for as the obliteration of the pleura proceeded from below upwards, the oil was driven to the upper part of the thorax where it was wanted. The oil generally used by the speaker was olive oil containing 5 per cent. gomenol, although for greater permanence liquid paraffin might be used. The amount of oil injected at a sitting varied from 5 or 10 c.cm. in cases of recent effusion up to two pints in cases where the fluid had been present for some time. Patients appeared to like an oleothorax and to be quite unconscious of the presence of the oil. Cases of tuberculous empyema were also best treated by replacement by antiseptic oil.

Discussion.

Dr. L. S. T. **Burrell** said that effusion was most uncommon in artificial pneumothorax for any case but tuberculosis. For example, effusion was practically unknown in abscess of the lung or bronchiectasis. The fluid was therefore a true tuberculous effusion, and was not caused by hot air, cold air, or factors of this kind. Practically every tuberculous patient was found *post mortem* to have adhesions, due to a previous pleurisy, and on theoretic grounds, therefore, they would expect to find pleural effusion in an overwhelming number of tuberculous cases. There were two groups of spontaneous pneumothorax cases: one of these cleared up quickly without the formation of effusions; the second group was complicated by fluid. These last were probably tuberculous. Dr. Burrell went on to discuss why one of the earliest sounds of fluid in the chest should be a metallic tinkle. Pressure at first was not raised, but on the introduction of a little gas it was raised. When fluid appeared in a case of artificial pneumothorax, a lung previously partly collapsed became completely collapsed. This was probably due to the fact that in the recumbent posture the fluid squeezed the air out of the cells and the lung did not then so readily re-expand. The presence of fluid was almost always associated with complete collapse of the lung.

Dr. S. R. GLOYNE said that the subpleural lymphatics were practically always infected in tuberculosis, and he suggested that this might account for the occurrence of an effusion and have a bearing upon the difficulty of absorption of the fluid. He thought that they were apt to undervalue the importance of the parietal pleura. Another point brought forward was the possible rôle of saprophytic organisms. It was difficult from a pathologist's point of view to believe that a needle could be inserted fortnightly over a long period without producing some degree of infection. He did not suggest that much harm was necessarily done, but he did think that these organisms might possibly be responsible for a certain amount of effusion, especially in lungs that were already damaged.

Dr. S. VERE PEARSON drew attention to a class of case, difficult to treat, in which the fluid appeared at two, or even three, levels, in different "pools." These cases required careful study by percussion and by stereoscopy, to ascertain which of the pools was of most importance, where it should be tapped, and so on.

Dr. G. MARSHALL suggested that effusions might be caused by trauma, especially in cases in which no local anæsthesia was used. With regard to the production of the coin sound he had found that it never could be produced in the cadaver, owing probably to the absence of tension in the walls.

Dr. G. T. HEBERT, speaking on the frequency of effusions in artificial pneumothorax, said that more than 80 per cent. of his patients probably developed this. In two cases of serous effusion in non-tuberculous patients, both of bronchiectasis, the fluid showed 70 to 80 per cent. of lymphocytes. The coin sound, he said, could be obtained wherever there was a big space and fairly rigid walls.

Another speaker drew attention to the value of infra-red rays in aiding the absorption of pleural effusions.

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting on Nov. 14th a note on the

Treatment of Lupus Erythematosus by Bismuth

was read by Dr. R. M. B. MACKENNA. The consensus of opinion, he said, was that this disease was the manifestation of a chronic toxæmia. Three forms were commonly found to-day: the first exhibited erythematous scaly lesions; in the second there were indurated lesions with little scaling or erythema but with horny plugs in the orifices of the sebaceous and sweat glands; whilst the third type showed marked erythema but with few scales. Metallic bismuth and oxychloride of bismuth were, he thought, of equal therapeutic value in the treatment of lupus erythematosus. Intramuscular injections of sodium bismuth thio-glycollate had not yielded better results than those of other preparations. Bismuth given by the mouth and in an ointment basis were not of much value. It was impossible to say how much bismuth any given case would require, or for how long treatment would have to be continued. Of 24 cases treated by intramuscular injections of bismuth since March, 1929, about a quarter were discharged as cured, a quarter would shortly be discharged as cured, and the remaining half were making variable progress. He had no proof that the cases discharged as cured were really cured, and it was possible that bismuth injections might only cause a temporary intermission in the course of the disease; unfortunately he could not give any information about the mode of action of bismuth in lupus erythematosus.

Eruptions due to Fungi.

Dr. ELIZABETH HUNT gave a brief report on some forms of cutaneous eruption due to fungi. The organisms isolated on culture were yeast-like fungi (including red, white and pink cryptococci, monilia, endomyces, torula), and trichophytons, including epidermophytons. It was clinically impossible to distinguish the type of lesion due to the different organisms. Cases occurred, as a rule, as isolated instances in a household and indirect infection seemed most likely responsible. An individual susceptibility of the skin might be inferred, but required investigation. Temporary reduction of Fehling's solution by the urine was sometimes observed in the acute stages. Four clinical types of lesion were described: vesiculo-pustular, erythematous vesicular, irregular scaling patches, and thick scaly patches with fissuring. The common characteristics of these lesions were that they were superficial, localised, circumscribed, very chronic, and very intractable. Dr. Hunt described acute attacks in which the vesiculo-pustular type of lesion predominated. The eruption might be localised, but was often widely distributed or associated with a generalised eruption of lesions of the erythematous and scaly types. In these cases the same organism had been cultured from lesions on scalp, arm, and a nail. This kind of case usually showed a yeast infection. Some of the cases were typical examples of cheiropompholyx, and in these no generalised eruption was observed. Infection of the nail was common in about one-third of the cases. Dr. Hunt emphasised the importance of recognising the nature of these cases where the question of an occupational dermatitis was involved.

PATHOLOGICAL SOCIETY OF MANCHESTER.

AT the opening meeting of the session Mr. GARNETT WRIGHT delivered a presidential address to this Society on the subject of

Linitis Plastica.

He related how he had operated on two cases of this disease. At the time of operation he had considered them to be undoubted cases of cancer of the stomach, and he had done a partial gastrectomy on each case. He was surprised in both cases to get a preliminary pathological report stating that the condition was one of extensive fibrosis chiefly affecting the submucous layer of the stomach with no sign of malignancy. The first patient died shortly after operation and the second died nine months later from secondary growths in the peritoneum. Brinton, said the President, had been the first to give a clear and full description of the disease, which he regarded as an atypical form of cancer in which there was an excess of fibrous tissue strangling the invading epithelial growth. It was possible to demonstrate the carcinomatous nature of the disease by staining the epithelial cells with mucicarmine. Most of the cases that had been followed up had died from carcinomatous metastases.

Prof. SHAW DUNN showed an interesting series of microscopic sections of linitis plastica stained with mucicarmine.

A discussion followed.

Reviews and Notices of Books.

PHARMACOLOGY.

An Introduction to Pharmacology and Therapeutics. By J. A. GUNN, M.D., D.Sc. Edin., M.A. Oxon., Professor of Pharmacology in the University of Oxford and Fellow of Balliol College. London: Humphrey Milford, Oxford University Press. 1929. Pp. 220. 5*s*.

"WERE angels to write books," wrote Oliver Goldsmith, "they would never write folios." Prof. Gunn had this thought in mind when he applied himself to the task of writing his little book. Many writers of text-books, in their desire to make their work exhaustive, become diffuse, or, on the other hand, achieve brevity by compressing into smaller space the contents of the larger books rather than by writing eclectically. Prof. Gunn has skilfully avoided both pitfalls, and in brief compass has set forth a presentation of pharmacology and therapeutics. It is wonderfully complete for an introduction to the subject, and can be warmly recommended to the student.

Applied Pharmacology. Third edition. By A. J. CLARK, *M.C.*, B.A., M.D., F.R.C.P., Professor of Materia Medica and Pharmacology in the University of Edinburgh. London: J. and A. Churchill. 1929. Pp. 529. 15*s*.

IN the preface to the first edition of this book, published in 1923, Prof. Clark stated that his principal aim was to try to bridge the gap between pharmacology and therapeutics, and to demonstrate as clearly as possible the connexion between the two subjects. That there existed a considerable demand for such a book is plain, since a second edition appeared in 1927, and now within two years we have to welcome a third. All the chapters have been revised, and some of them rewritten in the light of the knowledge obtained from recent investigation. Two new chapters have been added, one on the pharmacology of the skin, written in collaboration with Dr. G. H. Percival, and one on inorganic metabolism. The latter deals with the "milieu intérieur" of the body, and discusses the interesting question of water intoxication, which is at present regarded mainly as a laboratory phenomenon, but may have some bearing on the symptomatology of nephritis. The book gives a clear account of the most up-to-date physiological and pharmacological opinions. It gives a summary rather than a critical survey of modern views, and in some sections we would have appreciated a more judgmatical tone from a pharmacologist of such authority. But the book has achieved great popularity in its present form and thoroughly deserves further success.

CEREBRO-SPINAL FLUID IN HEALTH AND DISEASE.

Third edition. By ABRAHAM LEVINSON, B.S., M.D., Associate in Pediatrics, Northwestern University Medical School; Attending Pediatrician, Children's Hospital of the Cork County Hospital, Chicago. London: Henry Kimpton. 1929. Pp. 380. 35*s*.

THE fact that this edition is enlarged by more than 100 pages is an index both of the growth of our knowledge of the cerebro-spinal fluid since 1923 and of the author's endeavour to incorporate this new knowledge in his book. Among the additions we note particularly a considerable enlargement of the chapter dealing with the characters of the cerebro-spinal fluid in various diseases, and a new chapter on the fluid in infants and children. Additions have also been made to most of the other chapters, notably those on the anatomy of the structures associated with the cerebro-spinal fluid and on methods of examination of cerebro-spinal fluid for diagnostic purposes. Several gaps, however, remain to be filled. For example, there is no mention of the perivascular channels or Virchow-Robin spaces which, according to recent work, contribute largely to the cellular content of the fluid in various forms of encephalitis and myelitis; and although many new tests are described only one method for estimating the total protein and only three of the many colloidal tests are given. The omission of De Thurzo's bicoloured mastic and benzoin reactions, which are a distinct improvement on the original form of these tests, is a matter for regret. The subject of neurosyphilis merits more than the scant three pages which are devoted to it in this as in previous editions of the book. Apart from these omissions, criticism may be directed to the author's theory of the pathogenesis of the changes which occur in the fluid in diseases other than meningitis. Most of these changes are assumed to be due to "irritation of the meninges," which may be caused by chemical poisons, by the toxins emanating from a focus of encephalitis or brain abscess, or by the pressure of a cerebral tumour. This is one of those apparently simple explanations which become more difficult the more deeply they are probed. It leaves out of account many physical factors, such as venous obstruction and œdema of the brain, which produce changes in the fluid but which have no relation to the meninges. And it gives no help in any attempt that may be made to deduce from the changes in the fluid the nature or situation of the pathological condition which is causing intracranial hypertension.

These defects are, however, balanced by the large amount of information which the book contains in a very readable form, and by the numerous tables which supplement the text, and make the book a convenient work of reference. The bibliographies which follow each chapter are large and detailed and must prove of great assistance to those who wish to inquire more deeply into the many unsolved problems connected with the cerebro-spinal fluid.

THE NERVOUS SYSTEM.

An Introduction to the Study of the Nervous System. By E. E. HEWER, D.Sc., Lecturer in Histology and Assistant Lecturer in Physiology, Women's School of Medicine, London; and G. M. SANDES, M.B., B.S., Demonstrator of Anatomy at the Women's School, and Surgical Registrar at London Lock Hospital for Women. London: William Heinemann, Ltd. 1929. Pp. 104. 21*s*.

THIS book is primarily intended for students, and seems to be admirably fitted for its purpose. The clearness and simplicity of its description, and in particular the excellent grouping of connexions and tracts, will do much to obviate the dissatisfaction which must accompany the learner's search for facts throughout the multiplicity of authoritative works. The subject is treated from the physiological rather than from the anatomical standpoint. There appears to be a disposition on the part of the authors to send more traffic across the dorsal commissural bridge of the cord than it was built to carry. Whether this suspicion is well founded or not, however, makes no difference to our keen appreciation of the book. It is well produced, clearly printed, and illustrated by many good diagrams of the physiological type.

NUTRITION OF HEALTHY AND SICK INFANTS AND CHILDREN.

Second edition. By E. NOBEL, C. PIRQUET, and R. WAGNER. Translated by BENJAMIN M. GASUL, B.S., M.D. Philadelphia: F. A. Davis Company. 1929. Pp. 243. $3.50.

IN reviewing the second edition of this work last year we paid tribute to its originality and thoroughness, while expressing doubt as to whether the Pirquet system of nutrition was destined to penetrate beyond academic circles in other countries. In the meantime it has received some further measure of attention as a result of the tragic death of its originator, and the recognition throughout the world of his great services to pædiatrics. Dr. Gasul has now placed this work, originally published by Dr. Nobel, within the reach of all English-speaking readers, and we feel sure that his labour will be justified by the number of doctors who will find interest in its pages. Certain facts remain as a bar to the adoption of Pirquet's system in England and in America. First, one of the ideas which underlies Pirquet's hypothesis—that the balance of fat and carbohydrate is unimportant—is not in accordance with current opinion. Secondly, the fear, probably well founded, that the adoption of a far more complicated method of calculation would lead to diminished practical efficiency will deter teachers from advocating the general use of this system, much though they may find in it to admire. Nevertheless, those who are interested in nutrition, and in the treatment of alimentary disorders, cannot neglect the school of thought exemplified in this work, and will find in the arguments set out much common sense.

SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS.

Was muss der Praktische Arzt von der Chirurgischen Behandlung der Lungentuberkulose Wissen? By Dr. HANNS ALEXANDER. Munich: J. F. Lehmanns. 1929. Pp. 60. M.3.

THIS monograph, which is one of a series issued by the *Münchener Medizinische Wochenschrift*, gives a clear and concise account of the modern surgical methods of dealing with pulmonary tuberculosis. It is designed to help the practical physician who is not an expert in tuberculosis. There is a fairly full description of artificial pneumothorax with an account of the technique and complications, and a discussion on the types of case. Bilateral collapse therapy is given but little space. The operations of thoracoplasty and phrenic evulsion are described at some length; the combination of phrenic evulsion and artificial pneumothorax treatment is briefly noticed, as is the older operation of pneumolysis with paraffin wax. In all cases indications for particular forms of treatment advocated are clearly given. Numerous illustrations are included. Amongst these are four very instructive radiograms showing the after-results of spontaneous healing with retraction, and the good results after phrenic evulsion, artificial pneumothorax, and thoracoplasty.

SYMBOLIC PROCESS.

Its Integration in Children. By JOHN F. MARKEY, Research Professor in Sociology at the Connecticut Agricultural College. London: Kegan Paul, Trench, Trübner and Co., Ltd. Pp. 177. 10*s.* 6*d.*

THAT the child is the father of the man is amply demonstrated in the most recent approaches in psychology. Prof. Markey's book on the growth and elaboration of symbols in human behaviour—individual and social—is almost entirely expressed in behaviouristic terms and should thus prove attractive to physiologists, particularly neurologists. There is a simplicity in the behaviouristic approach to mental activity and human behaviour which appeals to those who show a single-needed devotion to laboratory technique and a trust in the results that it gives. But behaviourism cannot stand on that alone. It must be subjected to the logical categories inherent in the material with which it deals, and it has selected only part of the material—that is objective data without reference to those facts which are called mental. Prospective reference and persistence with varied efforts—terms we owe to Stout and Lloyd Morgan—enter, we think, into all mental growth, and therefore into the creation of symbols, individual and social. It is equally a matter of doubt whether the theory will survive the devastating criticism of Koffka and others of the Gestalt school of psychology. No discussion of ultimate principles, however, will diminish the practical value of this book. There are chapters on personal symbol formation and the influence of social relations which are altogether admirable, and to all those who engage in the study of the child mind the essay will repay close study for the facts and investigations alone, quite apart from the difficulties in theory which rise like spectres in every chapter.

MAN AND ANIMALS IN THE NEW HEBRIDES.

By J. R. BAKER, M.A., D.Phil. London: George Routledge and Sons, Ltd. 1929. With 43 plates and text-figures. Pp. 200. 12*s.* 6*d.*

THIS is a gay and most interesting account of the author's experiences and observations in the South Seas. Apart from the more purely zoological parts, which are chiefly for specialists, he discusses two subjects of wide interest. Following Rivers, Buxton, and others he has investigated the depopulation which has been so marked a feature of these islands in recent years, and has advanced on the work of his predecessors by getting a good deal of numerical information. He finds a remarkably high proportion of males to females (160 to 100), which is a contributory cause, and the rest he attributes to diseases brought by Europeans and to abortion; he gives no support to Rivers's conclusion that the chief reason for depopulation was the lack of interest in a life which had by white man's government been pruned of its ritual and excitements. The other curiosity is the hermaphrodite (intersex) pigs which are quite common and play a large part in determining the owner's rank in the social scale. Dr. Baker naïvely assures us (p. 39) that his qualification for dealing with such subjects as depopulation is "a thorough education in biology and scientific method," which is perhaps why he says (p. 115) that all snails are hermaphrodite!

DENTAL INFECTION AND SYSTEMIC DISEASE.

By RUSSELL L. HADEN, M.A., M.D., Professor of Experimental Medicine, University of Kansas. Philadelphia: Lea and Febiger. Pp. 165. $225,

MUCH has been written on the subject of dental infection and systemic disease but comparatively little of it has dealt with the experimental side, while this book is mainly concerned with the experimental basis for the theory of dental focal infection as a factor in general disease. Dr. Haden reviews the subject in a moderate spirit, and records the results of his own extensive experiments with critical judgment. An important feature of the work is the correlation of the radiographical, histological, and bacteriological aspects of dental infection whereby Dr. Haden succeeds in conveying an all-round conception of dental sepsis and its sequelæ. He uses the bacteriological technique advised by E. C. Rosenow and has succeeded in confirming Rosenow's experimental findings on elective localisation. These results have been much debated and most bacteriologists regard elective localisation as still unproven. Dr. Haden states that failure to produce Rosenow's results is due to a disregard of certain fundamental technical details, especially a correct oxygen tension and the use of special culture media. The comparison made between the bacteriological findings in cases of infected teeth with positive radiographic changes on the one hand, and pulpless teeth with negative radiographic evidence on the other, is interesting. Quantitative cultures show that a high percentage of the teeth in the last-named group are heavily infected, although the radiograms may show no evidence of bone changes. The last part of the book consists of 35 case reports illustrating various forms of systemic infection associated with dental sepsis. In all cases the diagnosis was based on careful bacteriological examination followed by animal inoculation. They form a group the more striking because all the data available have been carefully evaluated. We recommend this book both to doctors and dentists.

THE LANCET.

NDON: *SATURDAY, NOVEMBER 30, 1929.*

IE ROYAL COLLEGE OF SURGEONS OF NGLAND: THE POSITION OF MEMBERS.

WE notice in another column the occurrence of the aual meeting of the Fellows and Members of the yal College of Surgeons of England which was ld on Nov. 21st; the spirit and temper of the eting was such as to encourage the hope that a form, which has been pressed for in the columns THE LANCET for over 80 years, may come up for rious consideration by the authorities of the llege. In the early days of THE LANCET e frequent text of editorial articles was the istence of certain abuses in the College, and when e Charter of 1843 was obtained, changing the name the College to its present style and instituting the der of Fellows, criticism was not abated, although me of its earlier grounds were removed by the new ct. For it was perceived that, although the new arter had abolished the absurdity in a progressive d scientific calling of a small and self-elected verning body who could hold, and who alone could ld, perhaps for life, the examinerships designed to the tests of proficiency among their juniors—though this vestigial trait of a trading corporation d now disappeared from the constitution of the llege, there remained an illiberal provision, depriving e mass of the corporation from any voice in the nduct of their affairs. The officers of the College der the new Charter were, under altered titles, the me authorities as those who had previously been in wer, and to them the discretion was given of selecting e first body of Fellows. It is true that it was ovided that no more persons, after the lapse of e year, should be elected Fellows except after amination, but the examinerships remained in the nds of legitimate descendants of the old Governors, hile the new rulers were only to be chosen by the te of the Fellows and from out their own body. ranted that the senile examiner no longer inquired to the proficiency of the new recruits, still the new uncil represented the old Court of Assistants, d the new Council selected the first body of Fellows, d the Charter gave to the Fellows, and to the Fellows ly, the right of filling up vacancies in the Council they occurred. The Charter invited criticism, d has obtained it since its birth.

Now it is a remarkable testimony to the way in which e affairs of the College have been managed since 1843 at, although the weakness of the constitution has en pointed out with reiteration, and although from me to time individual and group remonstrances ve been addressed to the rulers and voiced in the edical and lay press, nobody has been found to say at the affairs of the College have been badly managed that the Council has been other than a competent d representative group of men, true and just in eir dealings. So much is this the case that ccessive Presidents have been able to point out, hen challenged, that the reluctance of the Council secure for the Members a place in the management College affairs has been due to lack of evidence at either the conduct of the College or the status of the Members has been injured by the provision of the Charter leaving the election of the Council in the hands of the Fellows. But it is one thing to say that an institution has not suffered through a loss of something and another thing to say that that institution would not have gained under modification. The College authorities have certainly been open to the accusation of self-satisfaction in taking no steps to consider what measure could be taken, within the provisions of the appropriate Act, to give to the Members an adequate expression of their desire to play their part in the activities, policy and development of the College. It may be said that at one time the Council has been asked to consider the extending of voting powers for seats upon the Council to the Members, and at another to arrange that a certain proportion of Members should have seats upon the Council; and that the two things not being the same no regulations of a reforming character would provide for both. But the difficulty has been pointed out many times, and could be removed at a meeting between the College and properly accredited leaders of reform, the one side saying exactly what they wanted, and the other what could be granted without the hideous task of securing a new Act of Parliament.

Alike because surgery is so living a thing and because the bulk of English practitioners are Members of the Royal College of Surgeons of England, it seems right that this question should receive serious attention with a view to settlement. In past times various Presidents of the College have had no difficulty whatever in refusing to listen to the claims of the Members, because sometimes those claims were put forward in a manner entirely prejudicial to those who were making them, and because on other occasions the vaunted support of numbers could not be proved. But to-day things are altered, for one of the main reasons for instituting an order of Fellows is disappearing. It was the abuse of the senile examiner that led to the institution within the College of an order of higher academic position, designed to form the material whence a court of examiners could be chosen, whose equipment should be level to the progress of their science. To-day this argument has no force, when all degree- and diploma-granting bodies have to choose examiners who have no internal connexion with the particular university or corporation, but who possess the paramount claim of familiarity with their subjects. With the disappearance of this argument for maintaining a deep gulf of distinction between the Fellows and the Members, the road to rapprochement becomes plainer. Frankly we wish that some overt move towards that road could be taken.

SUSCEPTIBILITY TO CANCER.

ALL who are interested in the cancer problem will welcome an authoritative statement on the present state of this problem which appears in the Twenty-seventh Annual Report of the Imperial Cancer Research Fund for 1928–29. In previous years comments on general aspects of cancer research have been included in the Director's Report. It is now intended to make such discussions a special feature of the annual reports, and this year Dr. W. CRAMER supplies a critical commentary on Experimental Carcinogenesis. Here is reviewed, in non-technical language, the work of the last ten years on the experimental production of cancer. Dr. CRAMER points out that some of our fundamental conceptions of cancer have been modified as the results of recent experimental work. Thus t [illegible] idence of cancer was formerly interpreted as showing that cancer arises in an organ or in tissues which are senescent. Experimental investigation of carcinogenesis has shown that the development of tar cancer requires a long period of induction. In the mouse the period of induction is hardly ever less than three to four months, but may be much longer—eight to nine months. In man the period of induction can be estimated from cases of occupational cancer; the minimum is seven years, the maximum as high as 20 years. At first sight there seems to be no obvious relationship between the figures for mice and men. But when one considers that the maximal span of life is three years for a mouse and 90–100 years for man, it becomes clear that three months represent approximately the same fraction of its span of life as seven years of human life—an example of a relationship for which Dr. Cramer suggests the name of biological relativity. This relationship may be found to hold good for many biological processes, which proceed more quickly in the cells of the short-lived animals than in cells of long-lived organisms. That the long period of induction is the correct explanation of the peculiar age incidence of cancer is now fairly generally held by those who have followed recent experimental work on cancer. A conception which is more revolutionary and far-reaching and is likely to meet with some opposition is the doctrine put forward by Dr. Cramer that susceptibility to cancer is a determining factor in its incidence. The implications involved in this doctrine will be made clear by its comparison with the orthodox view. In a recent rather pessimistic paper Prof. James[1] Ewing expresses the opinion that the problem of the ultimate nature of the cancer problem is "one of those types of information which will long escape the human mind." But he regards as one of the most important steps made in the investigation of cancer the recognition of the fact that cancer is not a single disease but a whole host of diseases. "We know," he says, "that there are just about as many clinical entities in the group of cancer as there are outside of them." There exists also a considerable body of knowledge regarding the various forms of chronic and specific irritation which are known to be necessary to the incidence of cancer. The difference between a person who develops cancer and one who remains free from it is that in the former person one organ has been subjected to chronic irritation while the habits and mode of life of the latter have been such as to avoid chronic irritation. On such a conception it is reasonable to expect that the incidence of cancer could be diminished if we traced for each organ the forms of chronic irritations which lead to cancer and, having gained the knowledge, took steps to avoid them.

Dr. Cramer advances statistical, clinical, and experimental evidence to show that such a view is too simple. The statistical data given in last year's annual report show that the total mortality from cancer in women is approximately the same in different countries, from which statistics of equal reliability are available, although the organ incidence varies greatly. Similarly, the total mortality in men and women of the same country is approximately the same, although the organ incidence necessarily shows considerable differences. If cancer were a whole host of diseases, each organ having a separate ætiology and representing a self-contained unit, the total incidence of cancer would have to be regarded merely as the sum of the incidence in the different individual organs and should increase or decrease as the incidence on this or that organ increases or decreases. The statistical evidence shows that this does not happen, but that some mysterious law of compensation appears to be at work, which provides that whenever in a comparison of two populations there is a markedly lower incidence of cancer in one organ, there is a correspondingly higher incidence of cancer in at least one other organ. This mysterious law of compensation finds an explanation in the fact, which can be demonstrated experimentally and which also appears from the clinical evidence provided by occupational cancer, that the same forms of chronic irritation applied in an approximately equal degree do not produce the same effects in different individuals. In some cancer appears after a relatively short interval, in others after a much longer period, while a third group remains free from cancer. In occupational cancer, for instance, the number of individuals who develop cancer are only a fraction of the number who have been exposed to the specific chronic irritation. Cancer and freedom from cancer are, therefore, not merely a question of presence and absence of chronic irritation. The susceptibility of the organism to respond to chronic irritation with cancerous growth enters as an important factor. It determines the number of people who, as the result of the various forms of chronic irritation incident in our lives, will develop cancer. That approximately the same number of men and of women develop cancer while the organ incidence in the two sexes shows considerable difference is, from this point of view, the expression of an equal susceptibility in the two sexes. Since in women breast and uterus are two organs particularly exposed to chronic irritation, a considerable number of women die as the result of cancer of these two organs and therefore the number of susceptible women who can develop cancer of the other organs are correspondingly diminished, as compared with the number of susceptible men. The argument is closely reasoned and should be carefully studied. It leads naturally to the conclusion that "freedom from cancer is more likely to be attained by diminishing the susceptibility to cancer than by trying to hunt down the various forms of chronic irritation to which we are exposed and devising means to avoid them." Investigations are being carried out to determine, if possible, the factors on which susceptibility depends.

The Director of the Fund, Dr. J. A. Murray, F.R.S., in his report summarises the work published from his laboratories in the year under review. The work on the filtrable tumours of the fowl by Dr. A. M. Begg has been recently reviewed in our columns.[2] Mr. H. G. Crabtree has continued his studies on the metabolism of cancer cells by applying O. Warburg's method to a great variety of strains of transplantable mouse tumours. The result is a confirmation of Warburg's discovery that malignant cells possess the faculty of splitting sugar into lactic acid to a far greater extent than normal cells. This property, however, is not specific for malignant cells, so that it cannot be applied as a criterion of malignancy. But since the type of metabolism possessed by cancer cells must determine to some extent their biological behaviour, it is an explanation of some features of malignancy. It would be a mistake to underrate the importance of this discovery because it does not reveal the whole secret of cancer. Of considerable interest is the work of Mr. R. J. Ludford, D.Sc., on vital staining of malignant cells. Cells are said to be vitally stained when they are able to take up certain dyes and segregate them in the form of droplets during the lifetime of the animal. The idea underlying Dr. Ludford's investigations is that there is an essential similarity between the process of vital staining by certain dyes and the chemotherapeutic action of metallic colloids. These colloids, when injected intravenously, are taken up by a certain type of cell, the macrophage, which also has a high capacity for becoming vitally stained. The cells of malignant new growths do not stain vitally to the same extent as their normal prototypes. This raises the interesting question whether the action of metallic colloids is not an indirect one, exercised through the macrophage type of cell. The point is of importance in view of the therapeutic results obtained by means of colloidal lead. Dr. MURRAY, referring to the work of Dr. A. T. TODD of Bristol, who has worked out a modification of the colloidal lead treatment originally introduced by Prof. BLAIR BELL, states that Dr. TODD's results "prove conclusively the possibility of bringing about the disappearance of some tumours, definitely malignant, with prolongation of life by the intravenous injection of certain colloidal lead preparations." This result could be obtained only in a percentage of the cases to whom this treatment was applied, and in some cases in which regression of the primary tumours took place some of the metastatic growths proved resistant to the action of lead colloid. The evidence indicates that the action of the lead colloid is not a direct toxic one but that a more complicated mechanism is at work.

[1] Cancer as a Public Health Problem. Public Health Reports, 1929, xliv., 2093.

[2] The Lancet, Oct. 26th, 1929, p. 886.

In recent years the literature of cancer has not been free from a sensationalism unfitting to this grave subject. Observations have been offered on the problems of the treatment and the ætiology of cancer which are based on inadequate evidence. On the other side there has to be fought the sterile pessimism of those who believe the problem to be unsolvable. The annual report of the Imperial Cancer Research Fund always steers a safe course between these two extremes. The difficulties inherent in the problem are admitted; the failures are not concealed; credit is given to successful work done in other laboratories; and the general tenor of the report shows the steady advance in our knowledge which is the reward of patient work.

WHAT SCHOOL-CHILDREN DIE OF.

THERE seems to be a fairly widespread opinion among the laity at the present time that the commonest cause of death among school-children is the motor-car. And indeed, in Sir GEORGE NEWMAN's report on the Health of the School Child[1] for 1928, violence—presumably most frequently received in street accidents—ranks second only to tuberculosis as a cause of death between the ages of 5 and 15 years. Yet nowhere in the book are preventive measures discussed or recommended; "violence" seems to be regarded by the authorities as an act of God, and is treated with the same respect as that which the ancients accorded to epilepsy. Surely protection of life against this danger is as important as against any other, and should equally be the concern of educational authorities. It is with the prevention of disease, however, and especially infective disease, that the report is especially concerned.

Tuberculosis in its various manifestations accounted for 2173, or 16·4 per cent., of the total deaths and remains the chief menace to life among children of school age, but the report includes tables showing the marked decline in this disease since 1907. That variations in conditions and food have an important bearing is indicated by the rise in mortality due to this disease during the four years of the late war. An efficient school medical service is the most valuable factor in obtaining early diagnosis as a preface to thorough preventive and therapeutic measures. Meningitis and other diseases of the nervous system were responsible for 1116, or 8·4 per cent., of the total deaths of the year. The problem of fatal nervous disease following vaccination has attracted considerable attention; in 1928 out of a total of 55 "post-vaccinal nervous diseases" in the whole country, 30 occurred in children between the ages of 5 and 14 years, and of these 19 were fatal. It was pointed out by the Rolleston Committee that this manifestation was extremely rare after revaccination and after vaccination in early infancy. The danger is to the child between 5 and 15 years who has not been previously vaccinated. Measles remains a serious danger to childhood by reason of its complications; much has been done to avoid these by instructing parents in the dangers of the disease, by health visiting, and by the power of the local authorities to provide nursing and medical assistance in epidemics. But the incidence is unaffected by these measures, and is greatest in overcrowded and insanitary slum districts, and among children under 5 years of age. As the mortality is much less among children above this age, the attention of the school authorities at present is directed to postponement of incidence to later ages, to provision of early and adequate nursing treatment, and to early diagnosis of the disease and removal of the infected child. The case-mortality per cent. of diphtheria, since the introduction of antitoxin in 1895, has decreased from 30 to 3 per cent., but, as if partly to balance this enormous gain, the incidence has remained higher during the last nine years than for many years before the war, and in 1928 the disease was responsible for 1565, or 11·8 per cent., of the deaths at school age. Sir GEORGE NEWMAN advises a wider use of the Schick test for determining susceptible individuals; over 90 per cent. of children under 5 years are susceptible, but immunity increases with age. Immunisation has been much improved during the last few years, and three doses of toxoid and antitoxin will now secure complete immunity in 80 to 90 per cent. of children. As the immunity takes a few months to develop the method should not be employed during an epidemic, and 17 local authorities in and around London are offering facilities for immunisation. The immunity lasts for not less than seven years in 95 per cent. of persons. It is obvious what a valuable protection would be offered by a wider use of this preventive measure. The experimental and investigational diphtheria carrier clinic at Guy's Hospital has lately produced its first report. In this the cure of carriers by means of operative

---

[1] Annual Report of the Chief Medical Officer of the Board of Education. Stationery Office. 1s. The principal causes of death among the children of England and Wales aged 5–15 in the year 1928 are given as:

Disease.	Number of deaths.	Per cent. on total deaths.
1. Tuberculosis	2,173	16·4
2. Violence	1,607	12·1
3. Diphtheria	1,565	11·8
4. Bronchitis, pneumonia, and other respiratory diseases	1,528	11·5
5. Meningitis and nervous system ..	1,116	8·4
6. Heart disease	822	6·2
7. Measles and whooping-cough ..	551	4·2
8. Rheumatic fever	513	3·9
9. Appendicitis	473	3·6
10. Acute and chronic nephritis ..	276	2·1
11. Acute infective osteomyelitis ..	255	1·9
12. Influenza	237	1·8
13. Scarlet fever	231	1·7
14. Tonsillitis, &c., adenoid vegetations	200	1·5
15. Other conditions	1,733	12·9
	13,280	100·0

is not an easy matter to excuse. Even in the larger towns the works are often either obsolete or of insufficient capacity; few produce a satisfactory effluent.

The Rivers Pollution Act of 1876 and the Salmon and Fresh Water Fisheries Act of 1923 are either ineffectual or insufficiently applied. The difficulty, of course, is that the treatment of sewage and the prevention of pollution are the responsibilities of the local authorities, and these are frequently in too weak a financial position to carry out the reforms required. In the case of trade effluents the problem is not so straightforward; many manufacturers regard the river as a legitimate outlet for waste products, especially if they made use of it with impunity before the 1923 Act was passed. Others, while prepared to take steps for the purification of the effluent, have been at no pains to discover the most suitable method, and either make use of some inappropriate means, or are content with half measures. Occasionally the manufacturer is ignorant of the damage resulting from his waste products, more especially if these are in the nature of food material, such as beet-sugar or condensed milk. An instance in which this occurred was responsible for considerable damage to fish life; the milk products in the process of decomposition gave rise to various highly toxic substances while at the same time they robbed the water of dissolved oxygen. In a case occurring last July, a farm on the River Gipping became unsaleable, and certain of the stock died as a result of pollution of the stream by an acetate silk factory. The situation becomes intolerable if, in order to encourage industry, such an important essential as unpolluted waterways is to be sacrificed. There is no necessity for this objectionable state of affairs; nearly all trade effluents can be rendered harmless, and most of the rest can be substantially improved by chemical means. It is difficult, however, to enforce these measures when manufacturers are aware of the defective treatment of sewage. It will be remembered that at the summer meeting of the British Medical Association Dr. H. McLean Wilson, chief inspector to the West Riding River Board, advocated the formation of more river boards as the best method of attacking the problem. These can supervise the rivers and their tributaries, paying particular attention to sources of possible pollution. The cost of such boards is comparatively small; that of the West Riding amounted only to a rate of one-seventh of a penny. Whether such organisations would be sufficient to control the nuisance is not quite certain. They could undoubtedly do much by way of detection of pollution and advice on its elimination.

The problem of catchment areas for large towns, and the guarantee of water-supply for new town-planning schemes enlarge the scope of inquiry. Joint committees for town-planning can do much in conjunction with the water authorities to prevent pollution of rivers and underground sources of water which may supply more distant areas. The protection of catchment areas, as in the case of that of Manchester, can be enforced by suitable regulations. Various minor points all play a part in the question of maintaining unpolluted streams. In some cases effluents do harm by being introduced into a relatively stagnant part of the river—that is to say, in the shallows close to the bank. It is essential that an effluent should be introduced where the flow is rapid in order that it may be diluted as quickly as possible. This result can be obtained even more satisfactorily by mixing the effluent with river water prior to its introduction into the stream. Again, it is preferable to provide for the cooling and aeration of effluents before discharging them, more especially if the stream is small and the effluent of considerable volume. Hot non-aerated condenser water can be responsible for serious damage to fish life in a small stream.

To sum up, pollution of streams cannot be excused on the grounds of insufficient investigation of origin or ineptness of corrective measures. The work of those who have interested themselves in the problem all goes to show the entirely unnecessary nature of the evil. "The chief hindrances," said Dr. Firth, "are legislative and administrative." The annual report of the Ministry of Health for 1928–29, though making no proposals for amending the law, admitted that the growth of population and the improved standard of sanitation call for capital expenditure in the treatment of sewage which sanitary authorities may be unable to meet. Clearly the matter cannot be effectively controlled while it rests in the hands of small local authorities.

POST-VACCINAL ENCEPHALITIS.

RECENT figures published in Holland concerning the epidemic of "alastrim" in that country show that 15 deaths occurred among 578 cases. In relation with this outbreak, and between July 28th and Sept. 29th of this year, 8239 primary and 146,787 revaccinations were performed. Among these there were 59 cases of post-vaccinal encephalitis with 15 deaths between the beginning of August and Oct. 5th. Eight children believed to be suffering from this affection were treated by one, two or three intravenous injections of 10 c.cm. each of the serum of adults who had recently been vaccinated. Seven of these patients made a complete recovery. The treatment recalls the successful case published by Sir Thomas Horder in THE LANCET (1929, i., 1301), in which a child received 5 c.cm. of the serum of his mother who was vaccinated at the same time as he was. In this case the serum was given intrathecally, a route which theoretically holds out more hope of success. Netter,[1] in a commentary on the present epidemic of alastrim, is inclined to attribute the post-vaccinal encephalitis to the action of vaccinia alone. He does not, however, bring forward any fresh explanation of the very irregular distribution of the cases in different countries and parts of the same country when the same or very similar vaccine has been used, nor does he show any reason for distinguishing these cases from those following other diseases, such as measles and chicken-pox. He also returns to the hypothesis that passage of vaccine lymph through the rabbit in the process of lymph production is the origin of the cerebral complications, though there is evidence that post-vaccinal encephalitis may occur following the use of lymph which has never passed through the rabbit. A new feature in the Dutch report by Kuenen, Kniper, and von Loghem[2] is the occurrence of 14 cases of post-vaccinal encephalitis following revaccination, an event which was almost unknown previously.[3] Netter urges in support of the essentially vaccinal nature of the disease the experiments by Bijl and Fraenkel, 1929, which suggest that vaccine virus becomes more active after contact in vitro with normal brain tissue, and instances the curative effect of the serum of vaccinated persons. The former experiments do not seem sufficiently cogent to have much importance, but the latter might be significant if they were corroborated by further trial. Generalisation of neurovaccine virus in the rabbit and its propagation with production of lesions in viscera have been described by several workers, especially Douglas, Smith, and Price,[4] and Ledingham and Barratt in our issue of Sept. 7th. The experiments by C. Armstrong and R. D. Lillie[5] who produced pneumonia in rabbits by instilling vaccine lymph into the nares or trachea, provide further evidence of localisation in unwonted organs. In these rabbits the virus increased locally in the lungs, which it presumably reached directly, whereas in post-vaccinal encephalitis in man it has only been recovered from the brain with great difficulty, and is not more constantly present there than in other organs. There is no evidence so far of the production of specific lesions in the central nervous system of rabbits even after the intravenous injection of the most active strains of vaccine.

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE report for the year ending July 31st, 1929, presented to the Court of Governors on Nov. 27th, is the first report to be issued from the new building which was opened by the Prince of Wales on July 18th. Naturally it records a year of great activity. A division of public health has been inaugurated under the directorship of Prof. W. W. Jameson. It has been staffed on special lines, and its members represent various aspects of public health life and activity. A scheme of study in public health, framed on novel lines, has been drawn up. It is hoped that the scheme will succeed in coördinating the different branches of study into a combined and logical exposition of the whole subject of the public health. A new course has also been drawn up for tropical medicine and hygiene. One feature of the new arrangement in this subject is that the summer course ends before the beginning of July—a "stale" month, and one much occupied with congresses and meetings. The division of epidemiology and vital statistics has moved into the School from the National Institute of Medical Research. The study of experimental epidemics is being continued in conjunction with the division of bacteriology and immunology. An interesting feature of the School's work is the informal instruction given for short periods to medical officers proceeding abroad and the liaison work with other nations. Dr. Andrew Robertson has left the department of protozoology to work with the United Fruit Company of New York, in Tela, Spanish Honduras, and the School has been visited by teachers of tropical medicine from Berlin, Hamburg and Shanghai. A system of library services has been organised to supply information on any branch of the School's work to members of the staff and outside inquirers. The library has been expanding very rapidly, as has also the museum, which contains many interesting exhibits supplied by commercial firms. Research work, as always, plays an important part in the year's activities, and investigators have contributed from all over the world. The appendix gives a list of about a hundred original papers published during the year. One group of research is financed mainly from the Milner Research Fund, and another through the Ministry of Agriculture. Meanwhile the teaching work has continued with success. During the year, 166 students attended courses; they came from the Colonial and Indian Medical Services, the Royal Army Medical Corps, other Government services and missions, and they went to every part of the world, the majority to Africa and India.

The full programme of activities is not yet in operation, and the Governors look forward to an early expansion of the department of biochemistry, the section of applied physiology and the work of the School in relation to industrial hygiene.

COMING OF AGE OF THE TRELOAR HOSPITAL.

Sir William Treloar personally received the first patients at Alton on Sept. 7th, 1908, and the annual report for 1928–29 is therefore the "coming-of-age" report of this institution. It records 21 years of successful work, and declares proudly that few institutions can claim to have done so much for national health and efficiency in so short a time. The success is ascribed to the spirit of personal service inspired by the founder, a spirit which has earned for Alton the name of "The Happy Hospital," and secured a record of 95 per cent. success in treatment. Sir Henry Gauvain, in his medical report, traces the development of the work and the gradual changes in method and technique. Particular attention was first paid to the treatment of abscess and the prevention of sinuses, and next to appliances for the prevention and correction of deformity. Research of all kinds has always been a prominent feature of the work at Alton and has produced results, both positive and negative, which have been of great practical importance. On the whole, conservative treatment is regarded as the treatment of choice, and with it are included such adjuvants as heliotherapy and balneotherapy. The seaside branch at Hayling Island was inaugurated in 1912 to make full use of natural sunlight and natural bathing, and the artificial light department supplements the deficiencies of the climate. Intermittent light treatment has been found more beneficial than continuous exposure, so that the South of England may be held to offer better conditions than districts with continuous sunshine. The more exhausted and toxæmic a child is, the less is the indication for exposure to light, and much harm may follow the irradiation of unsuitable cases. Artificial light at Alton is chiefly used for lupus vulgaris. Where surgical interference is necessary it is supplied by the orthopædic department, which works in conjunction with the Portsmouth public health authorities.

Education has always been an outstanding element of the work at Alton. All children from the age of 2 receive daily instruction, and in intelligence and resourcefulness the sick often outstrip the healthy. Year by year discharged patients return to their schools none the worse educationally for their long absence. Special handiwork classes are a great boon to the dull children, and advanced handicrafts are taught to convalescents who will be too old for school when discharged. An early investigation showed that patients with healed tuberculosis could safely resume normal activities, and the boys at the College are not treated as invalids in any way. The cricket and football teams play on equal terms with village clubs, and secure a very fair average of wins. The College trains crippled lads to earn their own living, and succeeds in 80 per cent. of cases. The boys are taught leather work, bootmaking, and tailoring. Senior boys take a course of bookkeeping, and are prepared for open examinations. The combination of vocational and educational training is of great value, and the report claims that a selfish boy does not exist in Treloar College. It was at Alton, moreover, that it was proved that suitable heliotherapy can evoke an increase of nearly ten per cent. in mental activity.

It is gratifying to learn that financial support has been well maintained. The cost per bed per week is £2 1*s.* 7*d.*, and a good deal of rebuilding has become essential, as the buildings conveyed to the institution in 1908 were the old wooden structures of the Princess Louise Military Hospital. For this purpose a rebuilding fund has been opened and a special appeal issued. During the 21 years, to the end of last March, 4871 patients were admitted and 4528 discharged. The average length of stay was 405·2 days, and the total mortality 2·9 per cent. The Alton Hospital has a record of which it may well be proud, and we congratulate it on the attainment of its majority, and trust that it will go on in its maturity from strength to strength.

THE DENTISTS AND THE HAIRDRESSER.

Is the scaling of teeth an operation which amounts to the practice of dentistry, and which therefore cannot be lawfully performed except by a registered dentist? This question was put last week to the stipendiary magistrate at Bow-street, and seemingly was answered in the affirmative. Where an offence is not very grave, magistrates have a wholly praiseworthy habit of refusing to convict, even though satisfied that the prosecution has made out its case; they make the defendant pay something by way of costs rather than by way of penalty. The only disadvantage of this course is that it sometimes prevents the public from getting an authoritative ruling on a nice point of law. The facts in the Bow-street case were clear. A hairdresser in Lamb's Conduit-street had hung up in his saloon a notice saying "Teeth cleaned and scaled." Customers who came in to have their hair cut were invited afterwards to have their teeth scaled for half-a-crown. A summons was issued at the instance of the Dental Board. On receiving it the hairdresser wrote to the Board that he did no more than clean his customers' teeth with a match-stick and peroxide; this he regarded as beauty culture rather than dentistry. At the police-court he reiterated the contention that he merely cleaned teeth for the purpose of improving the appearance. He kept, he said, no dental instruments on the premises; if a customer had bad teeth requiring attention, he always referred him to a dentist; he was quite unaware that he was doing wrong, and he had now removed the notice from the wall of his saloon. Counsel prosecuting on behalf of the Dental Board had no difficulty in producing a definition of dentistry. Section 14 of the Dentists' Act of 1921 says explicitly that, for the purposes of that Act, the practice of dentistry shall be deemed to include the performance of any such operation and the giving of any such treatment, advice or attendance as is usually performed or given by dentists. Mr. A. T. Pitts, who was called by counsel to give evidence as to the process of scaling teeth, explained that tartar on the teeth was an injurious substance containing a number of germs which might set up pyorrhœa; the removal by scaling was a difficult matter requiring special instruments skilfully handled. This evidence, unrebutted, was presumably conclusive of the fact that the scaling of teeth is an operation usually performed by dentists. The magistrate said he thought the defendant had held himself out as being prepared to practise dentistry, but he dismissed the summons on payment of three guineas costs. It may be noted that the maximum penalty under the Act is a fine of £100. No doubt the magistrate was justified in taking a lenient view. At the same time, the Dental Board has no alternative but to bring such cases before the courts. If teeth-scaling by unqualified persons is to be sandwiched in between a shave and a hair-cut, it may soon become arguable that it is not exclusively a practice of dentistry. The mischiefs at which the Dentists' Act of 1921 was aimed will revive if amateurs are to be allowed to attack tartared teeth, and to decide whether or not the mouth is bad enough to justify reference to a dentist. If Parliament had —as nobody doubts it had—good reasons or conferring on the registered dentist a monopoly of practice which it refuses to the registered medical practitioner, the Dental Board would be false to its trust if it failed in vigilance.

DR. SAMUEL RIDEAL.

Dr. Samuel Rideal, whose death has been announced as occurring recently in South Africa, is well known by name to all chemists and many members of the medical profession as the inventor of the Rideal-Walker coefficient, a convenient method for the ascertainment of the comparative antiseptic power of disinfectant preparations. Dr. Rideal, who was a D.Sc. of London University and a Fellow of University College, was at the beginning of his public career lecturer on chemistry at St. George's Hospital; but he later devoted himself mainly to the study of disinfection problems and those of food preservation, to water purification, and to the chemistry of sewage. On all these subjects he wrote carefully and because of his familiarity with the difficulties of their study, and also because for a time he served as public analyst at Chelsea, he became president of the Society of Public Analysts as well as on different occasions examiner in chemistry at the English Conjoint Board. The Rideal-Walker method, immediately upon the publication of its technique, became commonly employed where it was necessary to compare the germicidal power of any preparation with that of some other disinfectant under carefully standardised conditions. Later, a method of accomplishing the same purpose was designed by the late S. A. Vasey, then chemist to THE LANCET, and this method has been much employed even while it became obvious in certain directions that it was open to criticism. A summary of the position was written in our columns by Rideal, and those who are interested in what at the time was a very live controversy will find the story set out by Rideal in a perfectly impartial way [1] in our pages. Dr. Eric Rideal, Humphrey Owen Jones lecturer in physical chemistry at Cambridge, is a son of the late Dr. Samuel Rideal.

THE ROYAL DENTAL HOSPITAL.

FOR very many years it has been the custom of the Royal Dental Hospital to hold an At Home on the same day as the annual dinner for old students and their friends. On this occasion clinical demonstrations are given by members of the staff, while a large number of interesting cases of rare conditions are collected. This year on Nov. 23rd over 300 former students and their friends attended the hospital. In the morning Mr. S. F. S. Steadman demonstrated the technique of regional anæsthesia; Mr. Bowdler Henry the preparation of the mouth for artificial dentures; and Mr. F. Talbot, the dental surgeon in charge of the newly established electro-therapeutic department, showed some patients under treatment. In the department where children with cleft palates are trained to speak, under the direction of Miss van Thal, several patients chatted to the visitors, and their clear enunciation testified to the value of the teaching. In the afternoon clinical cases were shown, also exhibitions of work in the various departments carried out by the students. Among the cases shown were several of dental and dentigerous cysts, including two examples of a very rare form of the last-named tumour—namely, a cyst arising in connexion with supernumerary teeth. Two cases of diffuse hypertrophy of the maxilla were shown. One patient who attracted some attention was a man of 40, with several unerupted teeth; two sisters of this patient showed a similar condition, and, in addition, defective ossification of the clavicles. The association of cranio-cleido-dysostosis with unerupted teeth as a familial disease has been noted in the literature, but cases are very rare. The orthodontic department was represented by a large number of children showing the results of treatment. The comparison of the original models of the jaws with the present condition of the patients showed how remarkable is the æsthetic improvement which can be obtained, and the boon which treatment can confer on children with unsightly irregular teeth. In the prosthetic department were a number of patients for whom unusual forms of dentures had been made. Obturators designed for cleft palate or to restore the maxilla after extensive operation for malignant disease were shown. The advances in substances available for dentures were illustrated by dentures made of new translucent materials, which reproduce the appearance of the gum in a way not possible with vulcanite. In the radiological department a large number of beautiful radiograms were displayed, and in the pathological department microscopic slides, specimens, and cultures. The John Hampton Hale research department was open to inspection, and visitors manifested especial interest in the investigations by Dr. E. W. Fish into dental caries and the nutrition of enamel and dentine. Many of the past students who visited the hospital in the afternoon reassembled at the Trocadero Restaurant at 7 P.M. to dine together and to greet their guests. Mr. W. J. May, who presided at the dinner, proposed the toast of the past and present students of the hospital and school, commenting on the wealth of clinical material available in the out-patient departments, which hitherto had constituted the whole of the hospital's clinical activities. From January next, however, ten beds would be reserved for Royal Dental Hospital cases at the new annexe of Charing Cross Hospital. Dentistry was not a soft job, but a hard and exacting profession, which nevertheless brought great rewards to its followers. Mr. E. D. Davis, in response, spoke of the determination shown by the authorities governing the hospital to keep up to date. They were fully conscious that dental surgery in modern times was not confined to the teeth, and that all diseases which had origin in the mouth should be considered in relation to it. The provision of beds and the use of an operation theatre at Charing Cross Hospital would help to show dental students how closely their activities were connected with those of the medical profession. Mr. F. F. V. Mansfield spoke of the revival of the Students' Society, and of the loyalty to the hospital, and the keen desire of the students to be well equipped for their future work. In two directions greater facilities were desirable; some of the students left the hospital without ever having extracted a deciduous tooth, and others had had little or no experience in giving gas. Mr. H. Stobie, the dean, spoke of the academic successes achieved. The examination results taken all round showed 70 per cent. of passes. A department of electro-therapeutics had recently been installed, and research work was in progress in all departments. Full advantage was taken of the facilities provided for post-graduate work. The Dean regretted the resignation from the staff of the honorary anæsthetists, Dr. Harvey Hilliard, Dr. C. J. Loosely, and Dr. E. H. Drinkwater, and announced that Dr. Lionel Smith, Dr. R. G. Karn, and Dr. F. P. de Caux had been appointed to succeed them. After a pleasant interlude of light music, supplied by Dr. Karn, the speeches were resumed. Mr. S. A. Riddett proposed the visitors in graceful terms, and Mr. W. Malcolm Scott, in reply, expressed concern at the diminished number of entries into the dental profession, in view of the possibility that dental benefit under the approved societies would become statutory. Mr. A. T. Pitts, in proposing the health of the chairman, recalled his own student days when Mr. May was a popular member of the honorary staff, always accessible and helpful to the students. Visitors to both the functions organised by the hospital on Nov. 23rd must inevitably have carried away the impression that this dental school is alive to its responsibilities, not only to students but to the general public, and is fulfilling them with zeal and success.

---

POST-OPERATIVE TETANUS.

It has long been recognised that the germination and development of spores of *B. tetani* which have gained access to the tissues depends on adjuvant factors. The mechanism whereby the defence of the tissues is maintained when the bacillus is injected in small quantities and appears to be ruptured in the presence of other organisms, certain chemical compounds, an accumulation of blood, or particles of foreign material embedded in the wound, is not clearly understood. Recent observations made in the department of bacteriology of the University of Edinburgh [1] show that the effect even of massive doses varies in different animals and in individuals of the same species. This experimental study was the corollary of a prior investigation into a series of cases of post-operative tetanus attributed to contaminated catgut. Catgut with spores embedded in it was introduced into various tissues and tetanus occurred with great regularity, but only provided a sufficient quantity of the material—i.e., the inoculum—was implanted. In the presence of a small inoculum a variety of agents are capable of predisposing to a tetanic infection, but the majority act somewhat irregularly. The influence of other infecting organisms in promoting the development of *B. tetani* was clearly illustrated. *B. welchii* exerted an adjuvant influence with great regularity, and a strain of *B. coli*, injected in large doses along with *B. tetani* spores in sublethal doses, evoked tetanus, though when smaller doses of *B. coli* were used results were negative. The peculiar relationship of post-operative tetanus to abdominal and gynæcological operations may be due to the fact that intestinal organisms favouring the development of the tetanus bacilli have gained access to the operation area. The authors discuss the nature of the inhibitory and adjuvant influences concerned in tetanus infection and suggest that these are complex. They seem to depend not only on phagocytosis and the oxygen tension of the tissues, but also on factors intimately related to the parasitic properties of the organism and the humoral and cellular defences of the body. The irregularity with which tetanus appears in animals subjected to experimental infection is well in accord with clinical experience. A batch of catgut afterwards proved to be infected has been used for a large number of operations with only a very small resulting incidence of tetanus. Experiments with iodised catgut demonstrated the efficiency of aqueous iodine in the sterilisation of this form of ligature for surgical use. Since, largely owing to the work of Prof. Mackie, sterilised surgical catgut can now be added to the substances in the Schedule of the Therapeutic Substances Act, 1925, this small but tragic group of post-operative fatalities should in the future be prevented.

We have to announce that Lieut.-General Sir Arthur Sloggett, who was Director-General A.M.S. on the western front from 1914 to 1918, died on Nov. 27th in his seventy-third year.

We have also to record the death of Sir John Cockburn at the age of 79 on Nov. 26th. He was a medical graduate of the University of London and practised medicine before taking up the political career which led to his becoming Premier of South Australia and afterwards Agent-General in this country.

In a report of the annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow allusion was made to Mr. Freeland Fergus as late instead of past president of the Faculty. We regret the slip, and are happy to say that the suggestion was entirely without foundation.

The annual meeting of the British Institute of Radiology, incorporated with the Röntgen Society, will be opened by Mr. Arthur Greenwood, Minister of Health, at 2.30 P.M. on Wednesday, Dec. 4th, at the Central Hall, Westminster. The Mackenzie Davidson lecture will be given at 3.15 P.M. on the same day by Prof. Gösta Forssell, whose subject will be the Radiotherapy of Malignant Tumours in Sweden. At 6 P.M. on Dec. 5th Prof. A. S. Eddington, F.R.S., will give the Silvanus Thompson lecture on X Rays in the Stars. Further particulars of the meeting will be found in our medical diary. The annual dinner will take place at 7.30 for 7.45 P.M., on Friday, Dec. 6th, at the Trocadero Restaurant, Piccadilly-circus, London. Mr. C. Thurstan Holland, F.R.C.S., the President, will take the chair, and application for tickets should be made to Major D. B. McGrigor, 32, Welbeck-street, London, W.1.

Derby City Hospital.—This poor-law hospital, which, when completed, will have 360 beds in 11 wards, has been opened by the Mayor of Derby, Alderman J. H. H. Grant. It is claimed that the building is the last word in hospital equipment, and that the X ray plant is "superior to that in any London hospital." By the movement of a lever the beds can be transformed into wheeled stretchers; 4000 pieces of crockery an hour can be washed and sterilised; and the medical officer is connected by telephone with every part of the building.

[1] Certain Factors that Promote the Development of the Tetanus Bacillus in the Tissues, with Special Reference to Post-operative Tetanus—an Experimental Inquiry. By T. J. Mackie, M.D., D.P.H., D. G. S. McLachlan, M.B., and E. J. M. Anderson, B.Sc. A Report to the Department of Health for Scotland. Edinburgh: H.M. Stationery Office. 1929. Pp. 31. 2s.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

LIV.

INTERPRETATION OF RADIOGRAMS OF THE ALIMENTARY TRACT.

PART I.*—GENERAL TECHNIQUE: THE ŒSOPHAGUS.

IN the radiological investigation of the alimentary tract there are certain fundamental difficulties to the uninitiated:—

1. X ray pictures are the result of the obstruction to the passage of the rays. They represent the shadows cast by all the substances through which the rays pass irrespective of their distance from the surface or from the X ray tube. There is no perspective.

2. The opaque food outlines cavities only in so far as they are filled—the actual wall of the cavity is not represented by any distinguishable shadow.

3. The whole of the alimentary tract is a living muscle. To understand it we must forget the cut-and-dried anatomical descriptions which give us the impression of an inert organisation of tubes which pass the food from the mouth to the anus. A living conception, especially as regards the stomach and duodenum, is fundamental. The possible variations within the limits of the normal are sometimes surprising, even to those with long experience.

Success or failure in diagnosis depends so largely on technique that one cannot eliminate it, even in a short article. It is not just the exposure of one or two films after an opaque meal—to imagine that a reasonably accurate diagnosis can be arrived at by such methods is as futile a conception as suggesting that one photograph can represent an ataxic gait. To arrive at accurate diagnostic results involves a tedious and well-thought-out examination which consists of: 1. Preparation of the patient. 2. Taking a brief history from the patient himself. 3. A series of fluorescent screen examinations, before and after the opaque food has been given, in which manipulation and palpation are freely employed. As many radiographs as may be necessary are taken of the appearances noted on the screen for record and demonstration purposes. 4. Summing up the evidence—that is, detailed examination of all the films, weighing up the notes of the screen examinations and also the clinical notes that have been taken. 5. Issuing the report.

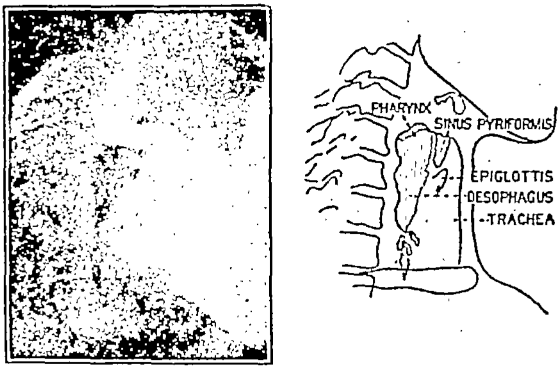
Preparation.

A purgative, two days before the examination and possibly an enema the day before, are necessary precautions against delay in the passage of the opaque food from mechanical causes. If the purgative is still acting when we examine the patient, it will give an impression of hurry that is as artificial as would be the delay of the opaque food by the stagnation in the cæcum or elsewhere in costive patients if no preliminary clearing had been carried out. In order that the stomach may be empty, no food is allowed for some hours before the examination. Apart from these precautions, the patient should live his usual life, for we wish to examine the alimentary tract under the least abnormal conditions we can arrange. During the period of examination purgatives should be avoided and the patient should conform as nearly as possible to his usual routine of life. When the examination is complete it is very advisable to ensure the voiding of the opaque food before it sets into a hard mass, as is liable to happen if no action of the bowels takes place for a day or so.

Technique.

The actual technique employed will differ according to local conditions—it must be so arranged that by a minimum of observations practically the whole alimentary tract will be observed. If the examination, therefore, starts early in the morning, the single opaque meal can be followed straight through till the evening; but if the first observations are made at, say, 2 o'clock, only a few hours are available and recourse is had to a system of double feeding. In these circumstances the first meal is watched from time to time for a couple of hours till all information as to the œsophagus, stomach, duodenum, and proximal small intestine is obtained. The patient comes for further observation on the following day, having had another opaque meal five hours before his appointment, preferably a real food mixed with opaque salt in order that, if there is a residue in the stomach, it will be a test under comparatively normal conditions. This method has decided advantages, both from the point of view of the convenience of the observer, and also because it gives greater opportunities for confirmations of observations, which are of the first importance.

FIG. 1.



Paralysis of the upper third of the œsophagus. The food sticks in the lower pharynx, particularly in the sinus pyriformis on either side of the larynx in the laryngeal pharynx and in the upper œsophagus. Forcible swallowing acts with difficulty and incompletely passes the food on.

Clinical History.

By taking the clinical history three main objects are obtained:—

(*a*) The radiologist can obtain personal knowledge of the history; frequently his experience indicates leading questions which bring out suggestive data, entailing variations in routine without which diagnosis would not be possible. As a simple example, a note that only certain types of food produce a sensation of œsophageal obstruction at once suggests that the opaque food employed should as nearly as possible correspond to the food that gives rise to the trouble.

(*b*) It gives the opportunity of getting to know something of the patient's mentality.

(*c*) An opaque meal cannot but be an ordeal to some patients, and a chat beforehand gives the radiologist the chance of allaying quite natural nervousness.

Screen Examination.

Presuming that the observer's eyes have been thoroughly prepared, either by the use of special goggles or by a period of waiting in the dark, the screen examination proceeds with the observation of the passage of the opaque food through the œsophagus and the rest of the alimentary tract, a number of observations being necessary at intervals determined by the rate at which the food passes and by other factors. This, however, is far from the whole story, for in addition to the use of his eyes the observer can manipulate the abdominal organs and judge from the movements of the shadows such things as undue fixation, laxity, or the cause of displacements. Even more important is the combination of the sense of touch with that of sight, from which combination he may obtain invaluable evidence as to the presence, site, and perhaps also the nature of any resistance that is detected, the reason for incomplete filling of any portion of the gut, the exact site of pain on deep pressure. It is essentially the work of a trained medical radiologist.

---

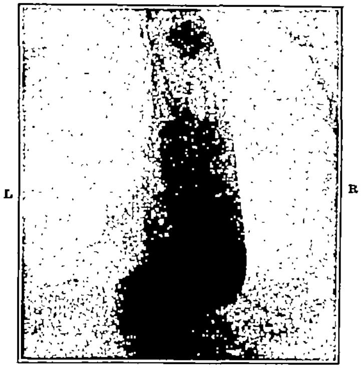
* Articles in this series on the other parts of the Alimentary Tract will appear in subsequent issues of THE LANCET.

A thorough screen examination is a very complicated and intense method of investigation. It requires absolutely undivided attention, for the observer may be put on the track of the cause of the symptoms by one transient observation which, of course, he must always attempt to confirm. In these observations it is essential for his own safety that he must be speedy, otherwise he is unduly exposed to radiations which will ultimately lead to disastrous results. In using his hands for palpation, whether bare or clothed in X ray proof gloves (which not only interfere with his sense of touch but also give him a false sense of security), he must never allow them to be in the direct beam of the rays. This can only be accomplished by using a very adaptable apparatus with which the illuminated area can be rapidly and easily cut down to a small focus and moved about over the organs that are under investigation, his palpating hand being always outside the illuminated area.[1] It is a complicated and delicate method of investigation that is as valuable as it is difficult, and it requires long experience to obtain the best results.

During the course of the screen examination X ray films are exposed as a record of what is seen on the screen. These are complementary to and cannot replace the screen examination. They record as far as possible such things as the radiologist notes on the screen. In this combined screening and filming technique it is seldom that the radiographs give the clue to the diagnosis—they merely confirm and record what has been noted on the screen. It very frequently happens, however, that the radiologist sees things on the screen which he is unable to record on the films—e.g., a duodenal cap which is irritable and can only be maintained normally filled for a brief period, a period that is quite sufficient to convince him that it is normal, even though his films show an apparent deformity, due to the partial filling of the cavity.

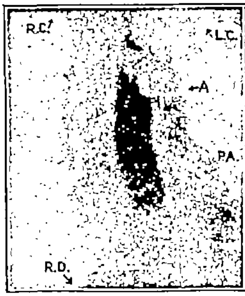
The technique of radiography should be absolutely standardised so that the radiologist need have no doubt as to the quality of the films he will have to examine when he makes his report—the exposing of the films is just an incident for record purposes in the course of his screen examination. He may, however, need a series of films to confirm the persistence or otherwise of certain conditions—e.g., that peristaltic waves miss out a certain section of the stomach, probably indicating an early growth, or that the deformity of the duodenal cap is persistently the same in character. Such serial radiograms need not be taken in very rapid succession, in fact they are of more value if they are made at intervals of a few seconds, since the average rate of peristalsis in the stomach is about three a minute.

FIG. 2.



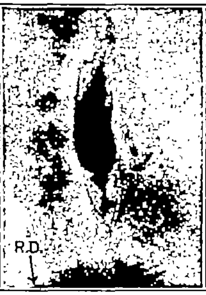
Old-standing case of cardiospasm in which the œsophagus has become much dilated and tolerant to holding large quantities. The act of vomiting—comparable to and very like the gush of pyloric obstruction—only partially empties the cavity. Note the thin tail of the little opaque food (indicated by a dart) that is passing the cardiac orifice. Also note that the increase in width of the œsophagus is accompanied by increase in length, so that the last few inches lie nearly flat on the diaphragm, forming an angle around which it is practically impossible for a bougie to find its way. Blind bougies should therefore never be used under any circumstances.

FIG. 3.



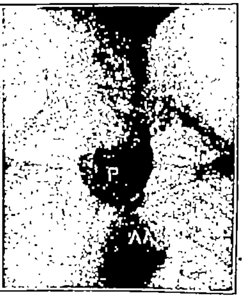
Œsophageal obstruction. The funnel-shaped lower end of the shadow suggests spasm—i.e., that the lesion is one affecting the mucous membrane. The film is taken in the semi-lateral position, but the patient is not sufficiently rotated to show whether the mediastinum is clear or not.

FIG. 4.



Œsophageal obstruction due to growth. Note the tortuous course but no displacement and a suggestion that the channel is in the middle of the growth. It is probably a growth in the wall of the œsophagus and its outline can just be detected on the film. It is indicated on the tracing by the dotted outline.

FIG. 5.



Typical œsophageal pouch. Note the rounded outline of the lower part of the shadow and the absence of any outlet.

R.C. = right clavicle; L.C. = left clavicle; A. = aorta; P.A. = pulmonary artery; R.D. = right diaphragm; P. = œsophageal pouch; AA. = aortic arch.

Interpretation of Observations.

It is most unwise, even in an apparently straightforward case, to attempt to arrive at a diagnosis without mature consideration. The radiologist should first carefully go through the notes that he has made of his screen examinations, examine all the films in detail, and then write out a précis of his observations which will form the first part of his report. This entails time and concentration. Not until he has done this should he attempt to draw conclusions and complete his report on the case. Having made up his mind as to the interpretation of the observations he has recorded in his précis, he should return to his original clinical history and see how his conclusions fall in with the clinical picture. Only when he has duly considered these things is he in a position to complete his report by adding his interpretation of the observations that he has recorded in his précis. It is mainly with the report and the grounds on which it is based that we are concerned in this brief outline.

---

[1] See the Dangerous Art of Palpation, British Journal of Radiology, (B.I.R. Sect.), October, 1926, xxxi., 365.

For the radiographic illustrations I am indebted to my late partners Dr. R. S. Paterson, Dr. E. W. Twining, and Dr. E. D. Gray of Manchester. These are not selected as show specimens but are the type of film that should be produced by any competent and properly equipped radiologist in reasonably easy cases.

For practical purposes the abnormalities that are met with in the alimentary tract are: (1) anatomical peculiarities and displacements; (2) disturbed function; (3) ulceration and the results of ulceration; (4) adhesions; (5) new growths; (6) the formation of diverticula. Various other lesions are occasionally met with, but they are comparatively so rare that we may almost neglect them—nor is it possible here to consider the displacements due to causes outside the alimentary tract.

Œsophagus.

When the patient is screened during the act of swallowing, the food is seen to pass over the back of the tongue straight down through the pharynx and into the œsophagus. Naturally, fluids and thin foods pass much more rapidly than thick. With fluids the process looks like the action of gravity, and the time taken to reach the cardiac orifice is not more than one or two seconds, whereas with thick pasty food, such as we use for œsophageal examinations, it takes perhaps 10 or 15 seconds. No indication of peristalsis is seen in the upper third and it is only when there is obstruction that we can definitely note peristaltic activity in the lower two-thirds. Normally the food bolus that is swallowed passes in an elongated mass at a more or less even pace all the way down, perhaps pausing momentarily at the cardiac orifice. When there is an obstructive lesion, particularly low down, we see the peristaltic wave pass down the column of opaque food as a ring of contraction and, as this approaches the obstruction, the opaque food regurgitates upwards through the wave of contraction, unless the pressure exerted is sufficient to canalise the obstruction. The appearance on the screen is almost as if the wave of contraction was passing from below upwards, as its effect on the shadow food is to shoot it upwards, leaving the immediate region of the obstruction empty. This appearance has given rise to descriptions of reverse peristalsis, which condition, so far as I know, is not actually to be seen in the œsophagus.

In the œsophagus there are no anatomical peculiarities, but displacements due to aneurysms, enlarged glands, and various chest conditions are common. Function is sometimes impaired owing to interference with nerve-supply. Normally a bolus of opaque food should pass down at an almost regular speed, fluids passing more rapidly than solids, and leaving practically no traces. When there is interference with the nerve-supply, the opaque matter tends to stick to the walls of the laryngeal pharynx and upper œsophagus. It is usually a case of repeated acts of deglutition, often accomplished with difficulty, before the food is passed down, perhaps with the help of a draught of water. Such an appearance indicates *interference with the nerve-supply* (Fig. 1).

The not uncommon condition known as *cardiospasm* (achalasia of the cardia) (Fig. 2) is also probably an example of disturbed function. There is marked obstruction at or just above the cardiac orifice that ultimately leads to enormous dilatation of the œsophagus. The character of the food seems to make little or no difference and, in extreme cases, one can fill the œsophagus up to the level of the clavicle with large quantities of food. A portion of this is usually vomited, the rest may pass on in time whenever the orifice relaxes. Twenty-four hour residue is, however, not very uncommon.

Simple ulceration of the œsophagus is rare, and gives rise to obstruction by reason of induced spasm from the irritation of certain foodstuffs. It is therefore important to make up an opaque food that is likely to set up the spasm or, as a routine stand-by, to give a mouthful of dry toasted crumbs before the opaque food is swallowed. The patient will always tell the observer when the spasm has been induced and he can then give the opaque food and note the position and nature of the obstruction (Fig. 3). Malignant ulceration may also be investigated by this bread-crumb method, and the obstruction due to the spasm may be noted long before there is organic narrowing of the passage. Naturally it is not possible to distinguish malignant from simple, specific, tuberculous, traumatic, or other ulcerations, except on purely clinical grounds, but the observer will take films and will also screen extremely carefully, in the upright semi-lateral position, to see whether or not there is abnormal shadowing around, and particularly below the site of the obstruction. Intrinsic growths with ulceration of the œsophagus seldom give any detectable shadow; those that extend to the œsophagus from the mediastinum are usually quite well seen on the screen. These *extrinsic growths*, however, are seldom associated with spasm, and the resulting X ray picture is one that suggests a narrowed, displaced, or tortuous passage of the opaque food through the obstruction (Fig. 4). It is a rather different type of picture from that of ulcerative obstruction, where spasm plays a large part and the lower end of the food shadow ends abruptly in a funnel-shaped tail.

The *œsophageal pouch* (Fig. 5) originates at the junction of the pharynx and œsophagus. As it gradually enlarges it sags down from this position, and the lower end of the shadow comes to a considerably lower level. The lower outline of a pouch is always rounded, with no suggestion of an outlet at the lower end. They are seldom detected before they are the size of a walnut. Diverticula also occur lower in the œsophagus, but they are very rare.

A. E. BARCLAY, M.D. Camb.,
Lecturer in Radiology, University of Cambridge.

A NEW CLINIC AT BIRKENHEAD.—Sir George Newman, chief medical officer of the Ministry of Health, on Nov. 20th, in opening a new clinic for children in Birkenhead, said that children to-day are healthier, better, stronger, weigh more, and are taller than children of 1907. The clinic represented the opening of the golden age of health. In the 1520 clinics throughout the country almost a million children received medical treatment last year, while another million had dental treatment. The Birkenhead clinic is the first in the country to be equipped with a cinema to educate mothers. It has a nursery and an artificial sunlight room, a sand pit, and a lawn.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—Our Dublin correspondent writes:—The report for 1928–29 of this Society furnishes sad example of the need that exists among near relatives of deceased members of the medical profession, as well as of the inadequacy of the Fund to meet the demands made on it. The Fund was fortunate during the year in obtaining a windfall in the form of a bequest of some £3500 from the widow of the late Mr. W. J. Hepburn, F.R.C.S. Edin., in addition to another smaller bequest. The actual increase from subscriptions, however, was a little less than £700, while the direct disbursement of grants came to £1644. The number of grants made was 83, and the average amount was £22 6s. 6*d.* How inadequate this is may be judged from the fact that in one case, in which a grant of £30 was made, the recipient's means from other sources were nil, while in some other cases the recipient was, apart from the grant from the Fund, dependent on the old age pension. The Fund is administered with great care and economy and deserves a more widespread support than it receives.

Special Articles.

GENERAL MEDICAL COUNCIL.

President's Address.

At the winter session of the General Medical Council, which opened on Nov. 26th, the President, Sir Donald MacAlister, recalled the fact that it was 40 years since he was admitted to membership of the Council, and 25 years since he was first entrusted with the responsibilities of the President's chair. "The time is drawing near," he said, "when I must resign into your hands the trust you have so long and so loyally reposed in me; but if you are good enough to consider that prolonged experience may in some measure compensate for lack of youthful vigour and initiative, I am willing for a little longer to continue my endeavours in your service."

A Retrospect.

"Forty years' retrospect," said Sir Donald, "satisfies me that, amid divers changes of operation and vicissitudes of public appreciation, there has been a steady advance, both internally in the Council's practical efficiency, and externally in its general estimation by the Government, the Judicature, the public, and the profession of medicine at home and abroad. The Council has not failed to respond to the progressive demands of the changing years, and, by those qualified to criticise and to judge, its efforts have been approved and encouraged. In the light of my long and intimate knowledge of its working I cannot but pronounce the Council to be to-day a better instrument for fulfilling in the public interest the duties laid upon it by the Medical Acts than it was 40 years ago. It is more harmonious, more zealous, better informed, and more happily inspired now than then."

Changes in Membership.

The President went on to record changes in the personnel of the Council. "Death has," he said, "taken from us Sir Thomas Jenner Verrall, a direct representative of English practitioners since 1912, an eager and fluent contributor to our discussions, of ripe experience in professional affairs, and zealous for the honour and welfare of the profession. Prof. Arthur Thomson has retired from the representation of the University of Oxford, after faithfully serving his university on the Council for nearly a quarter of a century. He carries with him our esteem for his sturdy independence of character, and our respect for his keenly critical intellect and his wide scientific knowledge. Mr. William Guy has completed his term of office as an additional member for dental business, originally appointed by the Privy Council in 1921. To his energy and his familiarity with dental education and policy the Dental Board owes much of its success in establishing itself as a new organ of professional government. Though Sir Edward Farquhar Buzzard has retired from his seat as representative of the Royal College of Physicians of London, we happily do not lose the benefit of his counsels. For the University of Oxford has done us the grace to appoint him its member here, and we heartily welcome him back. The Royal College has appointed in his room Dr. Henry Letheby Tidy, of St. Thomas's Hospital, and honorary secretary of the Royal Society of Medicine, whose repute as a physician and a scientific investigator has preceded him, and from whose enlightened coöperation we promise ourselves much profit in every way. As additional members the Privy Council has appointed two members of the Dental Board, Mr. John William Alexander McGowan, of Glasgow, and Mr. Edward Leo Sheridan, of Dublin, elected by the qualified dentists of Scotland and of Ireland respectively. With Mr. Dolamore for England we have now for the first time a dental member for each of the three countries. This readjustment removes from the Council one English additional member, Mr. William Robert Ackland, appointed last year; but he will still continue to serve his profession on the Dental Board, as he has been re-elected by the qualified dentists practising in England and Wales.

"The recent election of direct representatives to the Council has resulted in the unopposed return of Sir Norman Walker by the medical practitioners of Scotland, and of Dr. Leonard Kidd by those of Ireland, north and south. In the English constituency Dr. Brackenbury is assured of a fresh term of office dating from Jan. 1st, 1930; and Sir Jenner Verrall's place is filled by the election of Mr. Nathaniel Bishop Harman, who has approved himself highly competent in matters of professional administration."

Indian Medical Degrees.

The President then referred to the position of Indian medical degrees, and their recognition by the Council, as furnishing guarantees for efficient practice in this country, under the provisions of the Medical Act, 1886, Section 13. "In previous addresses, and in the minutes of the Executive Committee, you will," he said, "find particulars of the inherent difficulties of this question, and of the patient efforts we have made since 1922 to overcome them. I pointed out to you last May that the period for which recognition of Indian medical degrees for registration here was provisionally granted, pending the appointment of a Government Commissioner of Medical Qualifications and Standards, was fast running out. I stated that the evidence of separate inspectors, appointed ad hoc by the Government of India, had been received; but that their reports lacked reference to any common standard comparable with our own, and moreover disclosed individual deficiencies in regard to Indian methods of training and testing which could no longer be overlooked. I expressed the Executive Committee's earnest hope that the Government of India would not delay further its assumption of the responsibility, which rests upon it by law, to maintain such standards of medical qualification as would be acceptable for purposes of recognition outside of India. I endeavoured to make it clear, once again, that the Council is not concerned with the standards deemed sufficient for practice in the several Indian provinces. It is concerned solely with the standard which it is required by law to guarantee as in fact sufficient for efficient practice in Great Britain and Ireland. Qualifications admitted to the British Register must reach that standard.

"On behalf of the Council, on June 12th, 1929, I addressed a letter to the Secretary of State for India setting forth in detail the grounds for these conclusions, and pointing out the essential services both to India and to the Council, which fell to be rendered, in the absence of an All-India Medical Council, by a full-time Commissioner appointed by the Indian Government. His reports, authoritative, fully informed, and impartial, transmitted through the Indian Government, would be received by the Council with full confidence as a basis of action, and would furnish it with the guarantees that are indispensable for the due fulfilment of our statutory duties in respect of recognition. This letter was followed by communications from the India Office, stating that, as a temporary measure, the appointment of a whole-time Commissioner of Medical Qualifications and Standards had been agreed to by the Central and the Provincial Governments, pending the settlement of the permanent machinery required to enable the General Medical Council to discharge its obligations.

"These intimations were laid before the Executive Committee on July 22nd, when they agreed that, pending the confirmation of the appointment of the Commissioner, the recognition of Indian Medical degrees, which would otherwise cease on July 31st, would be continued until the meeting of the Committee in February, 1930. In August we were asked whether we agreed with the Secretary of State in thinking it desirable to offer the appointment to Colonel Needham. The reply was to the effect that, from our experience of the value of Colonel Needham's unique qualifications, we deemed the proposed appointment in every way desirable. In September we learned that Colonel

Needham had accepted the appointment, had made arrangements to leave for India on Nov. 1st, and was prepared to make his inquiries and report to the Executive Committee in time for its meeting in February. On Oct. 15th the India Office informed the Council that owing to action taken in the Legislative Assembly on Sept. 25th, the Government of India and the Secretary of State had felt obliged to cancel the appointment already intimated, and that Colonel Needham's departure for India was countermanded. The India Office further stated that the Legislative Assembly will meet again in January, and it was proposed to ask it to reverse its decision, and to explain to it, "not only the unfortunate results on the prospects of Indian students that would follow from a definite refusal to appoint a Commissioner of Medical Standards and Qualifications, but also the genuine desire of the General Medical Council to help India consistently with the obligations which British statutes impose on them."

"These perplexed and perplexing communications," said Sir Donald, "came before the Executive Committee yesterday, and I was instructed to inform the India Office that the final decision thereon must be postponed until the Committee's meeting in February next. But the inevitable absence of authoritative reports on the actual standards of study and examination for Indian medical qualifications would be of the most serious import. The Committee would in fact be deprived, by action taken in India, of the necessary guarantees of sufficiency, on the basis of which alone it would be in a position to extend recognition of Indian medical degrees beyond the period now current."

Qualifying Examinations.

"The Executive Committee, charged by the Council with making arrangements for the cycle of inspections of qualifying examinations to begin in 1930, have carefully considered the appointment of inspectors in medicine, surgery, and midwifery respectively. They have agreed to invite certain eminent and experienced members of the profession to undertake the important duty of inspection, and hope shortly to make definite appointments which will meet with the approbation of the Council. Visitations and inquiries have continued, at the instance of the Education and of the Examination Committee, in reference to the courses of study, and to examination requirements, bearing on important subjects of the professional curriculum. The visitations of recognised examinations for registrable diplomas in public health, sanitary science, and State medicine have been actively proceeding, and are indeed nearly completed."

The Pharmacopœia.

"This Committee," said the President, "will report on steps taken, and to be taken, with reference to the adhesion of this country to the proposed international agreement on the pharmacopœial unification of potent drugs, following on the International Conference held at Brussels in 1928. At this conference the Council was represented by the late Sir Nestor Tirard. The Committee will also transmit to the Council a report of progress made by the Pharmacopœia Commission since our last session. It will be found that the Commission has been diligently and fruitfully engaged in preparing for the issue of the British Pharmacopœia due in 1930, and has opened up communications with the British Dominions and with the United States which are likely to extend its usefulness."

At the conclusion of his address a vote of thanks to the President was proposed by Prof. J. B. Leathes, and seconded by Sir Norman Walker. The Council then passed to the consideration of penal cases.

HOSPITAL SAVING ASSOCIATION.—The annual report shows that the contributions during the past year amounted to £320,714, as compared with £248,878 in the preceding 12 months. There are now 6711 groups and 651,713 members, and during the year 172,467 contributors and dependents were treated at voluntary hospitals on the list of the association.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

THE annual meeting of Fellows and Members of the College was held on Nov. 21st, with Lord MOYNIHAN in the chair.

The PRESIDENT referred to points of special interest in the annual report of the Council, such as the examination for primary Fellowship held in Canada for the first time this year; the establishment of a research scholarship; and the formation of a British College of Obstetricians and Gynæcologists. With reference to certain provisions in its Charter which appeared to conflict with the powers and functions of the Royal Colleges no satisfactory compromise had, he said, yet been reached.

Dr. E. W. D. KITE asked whether it was true that in the examination for the Fellowship the examiners decided beforehand the proportion of candidates to be passed, and that once the number determined had been reached the remaining candidates inevitably failed.—Dr. F. W. COLLINGWOOD suggested that the Fellowship examination was no true test of operative skill, and that it should be revised in such a manner that this could be gauged.

The PRESIDENT said that it was not true that the proportion of successful candidates was decided before the examination. Every candidate was passed who reached the required standard; the proportion of successful candidates was small because the standard was high. Dr. Collingwood's criticism he considered was just; but unfortunately it was not possible to assess operative ability by means of an examination; it was possible only to judge whether the candidate had had a reasonable opportunity of acquiring it.

The report was then adopted.

Mr. SOMERVILLE HASTINGS then moved:—

> "That this forty-first annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation upon the Council of the College, in view of the fact that there were 18,687 Members as against 1945 Fellows."

He apologised for repeating an appeal which had now been made annually for over 40 years. In refusing to admit Members to the Council the Fellows were exercising a legal right, according to the Charter of the College. But that legal right had been obtained originally in an unjust manner, and he was calling upon the Council to right a previous wrong. If the Charter was examined, he said, it would be seen that in 1800 the Royal College of Surgeons of London was founded by Royal Charter, and the governing body of that day was elected by the Members. In 1843 the name was changed to the Royal College of Surgeons of England, and at the same time the degree of Fellowship arose. It was decided that the first Fellows should elect a Council, and needless to say they elected themselves, retaining the power to elect others without examination. The Members had suffered under a sense of injustice ever since. It was not, he said, that the Members were dissatisfied with the College; on the contrary, they wished to contribute to it. Most of the Members were general practitioners, a body of men essential to the coördination of medical services. The Council at present was in danger of becoming archaic; the Fellows did not encounter the general run of patients and were in danger of losing touch with the times. The examinations of the College, he thought, stood in need of revision. Was all the physiology included in the primary Fellowship of value to the surgeon? He appealed to the members of the Council not to harden their hearts against a reform which would be to their advantage.

Dr. H. S. STRATFORD, in seconding the motion, said that the arguments in favour of admitting

Members to the Council were both historical and practical. THE LANCET in 1845 had described the Charter, which "deprived members of the right to sit on Council," as "mischievous and iniquitous." He reasserted that Members wished to be represented on the Council not for their own profit but that of the State and community at large. During the war Members of the College had done an enormous amount of work, and the mortality among them had been relatively much higher than among the Fellows. The franchise had been accorded to women on account of their war-work. Members of the College needed a representative to voice their views and difficulties on the Council. The examination for the Fellowship was, he considered, not practical enough. Students should be signed up by their teachers for simple emergency operations such as tracheotomy, amputation, appendicectomy, before qualifying. In obstetrics practically all normal cases nowadays were attended by midwives; students were only trained to treat abnormal cases, and saw few that were normal. He was glad to see that a College of Obstetrics and Gynæcology was being formed.

Dr. REDMOND ROCHE said that the Council in 1907 had sent a circular letter to all Fellows and Members stating that although the Council had decided to admit women to the College, they were anxious to obtain the opinions of Fellows and Members. Now, in the report for 1929, the Council declared that, in view of the postal vote of the Fellows, it was not prepared to give Members direct representation. On the previous occasion the Council had made a decision and was ready to carry it out. Now the only reason given for refusing Members representation was the vote of the Fellows.

Dr. C. W. BROOKE opposed the motion. Members, he said, who really desired this reform should approach a Member of Parliament with a view to revision of the Charter. In the meantime, if the Royal College of Surgeons was an antique, it was at least a priceless antique, and should be preserved intact. He suggested that the President should rule this resolution out of order at future meetings.

Dr. ARTHUR HAYDON suggested that six Members should be elected to the Council and created honorary Fellows. If representation of Members on the Council was to remain impossible he was prepared to contemplate the formation of a new College.

In putting the motion the PRESIDENT said that, historically, the facts of Mr. Somerville Hastings were inaccurate; Members had never been in a position to elect the governing body; the original body had been self-elected. The large bulk of the Fellows were in general practice, so that the Council was in fact elected by general practitioners. Judging by the small numbers of Members who attended this annual meeting, the desire for representation in Council by Members was not widespread. Changes in the form of examinations had to be made gradually in order to be fair to the candidates. If there were any earnest desire among the Members for a change in the Charter, it could no doubt be altered legally, but until the Council was assured of that desire both Fellows and Members must continue to act under its clauses.

The motion was then put and carried, and the President announced his intention of submitting it to the Council.

BUCKSTON BROWNE ANNUAL DINNER OF FELLOWS AND MEMBERS.

The dinner held at the Royal College of Surgeons on Nov. 14th was the second of a series of functions to be held at the College, and due to Mr. Buckston Browne's generous gift of £5000, the interest of which is expended in providing an annual opportunity for friendly intercourse between Fellows and Members. In accordance with the terms of the trust, half of the company present at the dinner were Members of the College. Lord Moynihan presided, and the following is a list of those present, among whom it will be seen are several laymen whose personal connexion with the function was explained by Lord Moynihan in a few words.

Mr. W. R. Ackland, Dr. C. M. Anderson, Dr. H. T. Ashby.

Mr. Louis Baron, Mr. C. J. Bond, Mr. Victor Bonney, Mr. G. Buckston Browne, Mr. A. H. Burgess, Mr. R. H. Burne.

Mr. J. E. G. Calverley, Mr. H. W. Carson, Mr. Eustace Carter, Mr. T. Carwardine, Mr. D. K. Cassels, Dr. F. William Cock, Mr. Sydney Cockerell, Mr. Arthur Cooke, Mr. S. Forrest Cowell, Mr. S. C. Cresswell, Mr. V. A. Crinks.

Mr. Bernard Darwin, Dr. W. L. M. Day, Dr. John Dixon.

Mr. W. McAdam Eccles, Dr. H. Muir Evans, Dr. J. W. H. Eyre.

Mr. C. H. Fagge, Mr. J. Herbert Fisher.

Mr. H. Courtney Gage, Mr. Leonard Gamgee, Mr. A. J. Gardham, Dr. A. D. Gardner, Mr. G. E. Gask, Dr. Lewis G. Glover, Dr. R. N. Goodman, Sir Charles Gordon-Watson, Mr. Albert Green, Mr. C. H. Greenwood, Sir Wilfred Grenfell, Mr. Ernest W. Hey Groves.

Dr. George Hall, Mr. Sampson Handley, Prof. H. A. Harris, Mr. Ravensworth Hart, Rt. Hon. Arthur Henderson, Mr. R. G. Hogarth, Dr. G. H. R. Holden, Sir Thomas Horder, Dr. N. G. Horner, Mr. C. H. Howkins, Dr. William Hunter.

Mr. Leonard Isaac.

Dr. Thoresby Jones.

Mr. R. E. Kelly, Mr. Geoffrey Keynes.

Viscount Lee of Fareham, Mr. W. R. Le Fanu, Mr. E. K. Le Fleming, Mr. Hugh Lett, Mr. V. Warren Low, Sir John Lynn-Thomas.

Mr. C. E. A. MacLeod, Mr. W. Ernest Miles, Dr. J. L. Morton, Lord Moynihan.

Dr. F. E. Nichol.

Mr. Carlton Oldfield.

Mr. Herbert J. Paterson, Dr. C. J. Penny, Sir D'Arcy Power.

Mr. H. J. Relph, Dr. W. S. Richardson, Mr. Frank Romer, Dr. Thomas Rose, Mr. R. P. Rowlands.

Sir Percy Sargent, Mr. Graham Simpson, Colonel T. Sinclair, Prof. G. Elliot Smith, Dr. Alfred R. Spencer, Sir Squire Sprigge, Mr. F. J. Steward, Dr. C. A. Stidston, Mr. W. T. Storrs.

Dr. Edward S. Tait, Mr. Herbert Tilley, Mr. F. B. Treves, Mr. Thomas Turner.

Mr. Cecil P. G. Wakeley, Dr. F. J. Waldo, Sir Cuthbert Wallace, Sir H. J. Waring, Mr. James Watts, Mr. Russell Wilkinson, Mr. F. J. Willans, Mr. Henry Wilson, Mr. William Wyllys.

After the toast of the King, and allusion to the munificence of the donor, Lord Moynihan stated that the rule had already, he was glad to say, been laid down that no other toast would be proposed at this dinner, and that no response would be expected from anyone, but certain present, he thought, should be mentioned by name as having a connexion either with the function or with the College generally. To Mr. Louis Baron, he said, the College owed the foundation of the Bernhard Baron Research Scholarship of £500 per annum for seven years. They were all glad, he said, to welcome Lord Lee of Fareham, Chairman of the National Radium Commission, and Sir Wilfred Grenfell ("Grenfell of Labrador"), who had asked that no mention of the sort should be made of him, but his request was disregarded as the occasions were so few when he was seen at gatherings of his colleagues. Further, the President called attention to the presence of Mr. Arthur Henderson, Minister of Health; Dr. John Dixon, the Senior Member of the College, who obtained his diploma in 1854, and was 98 years of age; and Mr. Bernard Darwin, the well-known exponent of golf on the links and in the *Times*, and grandson of Charles Darwin. Lord Moynihan then requested the company to drink to the health of Mr. Buckston Browne.

After dinner Mr. Buckston Browne showed a film of Down House, Darwin's old home, which, it may be remembered, he presented to the nation at a meeting of the British Association in 1927, in response to an appeal from Sir Arthur Keith. Mr. Buckston Browne acquired the property from a grandson of the great naturalist, and transferred its possession to the British Association with an endowment for its upkeep and preservation, the condition being that the property should be regarded as a gift to the nation and open to visitors without charge. The film pictures included a view of Down House from the south, the lawn, the entrance to the Sand Walk, the study where Darwin worked, and the chair in which he wrote large portions of the "Descent of Man." In the course of demonstrating these pictures Mr. Buckston

Browne expressed the hope that Down House would be a centre of scientific research in connexion with the pursuit of surgery.

The guests on leaving were presented by Mr. Buckston Browne with a coloured reproduction of the portrait of John Hunter, which he had given to the College, and which is ascribed to Gainsborough. This portrait represents the plain, not to say ugly, Great John Hunter whose features Sir Joshua Reynolds idealised in his intellectual presentation.

ROYAL SOCIETY OF MEDICINE.

THE ANNUAL DINNER.

THE annual dinner of this Society took place on Nov. 21st at the May Fair Hotel, Lord Dawson of Penn, the President of the Society, occupying the chair. About 400 Fellows were present, and the guests included the Prime Minister, the Minister of Health, the French Ambassador (M. de Fleuriau), the Presidents of the Royal College of Physicians of London, the Royal College of Surgeons of England, the British College of Obstetricians and Gynæcologists, and the Medical Society of London; the President, Chairman of Council, and Medical Secretary of the British Medical Association; the President of the Medical Women's Federation; the President of the Royal Academy; and the Dean of Westminster. Among others supporting the Chairman were Commander L. C. Bornacchi, Sir James Berry, Sir John Bland-Sutton, Sir Walter Fletcher, Sir Arthur Robinson, Lord Lee of Fareham, Prof. Sidney Russ, Sir Albert Levy, Sir Alfred Lewis, Mr. Hugh Macmillan, and Dr. Kay Menzies.

The King's Health.

The toast list opened auspiciously, for the chairman, in proposing the loyal toast, took occasion to make a welcome pronouncement on the King's health. He said: "Upon this day last year there began that grave illness which nearly cost the King his life and the nation a beloved Sovereign. This is a suitable gathering in which to state that the King, in his recovery, goes from strength to strength."

The Prosperity of the Society.

The toast of the Royal Society of Medicine was proposed by the Prime Minister, who offered a tribute of praise to the medical profession, speaking as a private individual and as a public servant. He would leave to the Minister of Health the task of entering into details which, he believed Mr. Greenwood had discovered, occasionally raised somewhat thorny questions between the profession and himself. It was one of the great demands made upon a Prime Minister's time and intelligence to shift difficulties upon other shoulders, and to take smoother paths than his Ministers were sometimes able to choose. Comparing the modern doctor with the modern politician he found certain resemblances. Both were now less interested in cures than in maintaining the general health of the community. He had noted, also, that the medical profession was becoming much less interested in close and detached examination and consideration of an organ than it was in the harmonious and healthy inter-relation of the organs promoting the general health of the body, and here, again, was a point of contact with the politician. Standing in front of this gathering he felt that he was speaking to those who belonged, in some mysterious sort of way, to a common brotherhood. He had to couple with this toast the name of Lord Dawson, who was an old acquaintance of his. They had first met during Lord Dawson's student days, at a most respectable supper, issuing together towards midnight, both bound for the north of London. Their combined wealth that night was insufficient to save them from walking from the south end of Gower-street to Holloway station. A third party present at that meeting, however skilled in prognosis, would hardly have forecast that it would be their fate not to meet again until 40 years later they were fellow-guests at Buckingham Palace.

Lord Dawson, in response to the toast, claimed the Prime Minister as an apostle of the art of healing, for had he not recently been engaged in trying to allay and heal international strife? More than that, he had had the skill and understanding to try to institute a state of immunity amongst nations against the virus of war. It fell to the President of the Society to give an account of it. It was faring well; its finances were such as would satisfy even the Chancellor of the Exchequer. Beyond the Society's ordinary Budget, there was instituted, a little more than a year ago, a "Royal Society of Medicine Trust," the object of which was to further learning and to help young men who were engaged in research, especially by placing before them such works as would help them to pursue it effectively. An anonymous donor had recently given a donation of £1000 to this fund. Lord Dawson spoke of the advances made during the past year, especially the wider knowledge gained of the applications of radium and the organisation of its availability. The researches which had revolved round radium, vitamins, and hormones had revolutionised thought in the same way that, years ago, bacteriology had revolutionised it. We had got away from the conception of mass and weight, and had moved from matter to influence, from the static to the dynamic. The recent outcome of research into distemper was especially satisfactory, since its credit would fall to this country, where friendship between man and dog was a matter of national pride. The research was a fine exemplification of team-work. With regard to the application of medicine to the services of the country, the Local Government Act had opened up a new chapter in the relations of the medical profession to the Government. It was a satisfaction to medical men to know that the Minister of Health shared the belief that the secret of progress in health services depended on a responsible relationship between the medical profession and the local authorities. In that part of medicine which abutted on administration and on the interpretation of knowledge for the public good, the profession sought close relationship between themselves and the administrative bodies. In the territory which concerned itself with knowledge, education, and research, medicine must remain for ever unfettered.

Possibly the best way of bringing knowledge to the service of the people would be to set up semi-autonomous bodies with members having administrative and specialist knowledge sitting together, which would bring about quickness of decision and flexibility of thought. It would be the most rational form of delegation. The experiment had already been tried in respect of broadcasting, and of electricity; and the best and the latest example of all was the organisation of the nation's supply of radium, which organisation would commend itself to the consideration of all thoughtful people.

The Maintenance of Voluntary Hospitals.

Dr. A. P. Thompson submitted the toast of the guests. He said that statesmen, like physicians, were great borrowers; they had to acquaint themselves with all sorts of advances in human knowledge and ingenuity, in order that they might be brought to fruitful use in the community. On the subject of the voluntary hospitals, he said that to him people who talked glibly and cheerfully about the disappearance of great free institutions like the voluntary hospitals appeared as reckless of the future of this country as they must be ignorant of its history and character. The spirit of disinterested work manifested in voluntary hospitals was one of the treasures of our race, tradition, and inheritance. The sources of weakness of the voluntary hospitals seemed to be two-fold: (1) their lack of coöperation with one another and with established public health services, (2) their poverty. He believed the working man would make sacrifices to preserve the voluntary hospitals. In Birmingham, a coöperative scheme had been established, which, in two years, had resulted in a membership of 300,000, and in the collection of £200,000, all the work having been done by voluntary effort. Great changes affecting the profession of medicine in its relation to the public were everywhere being discussed, and were mostly acknowledged to be inevitable. It would be idle to deny that certain tendencies had given cause for uneasiness, even alarm. It had been said that the day was approaching when the State would control all the medical services in this country, and that the first great step to this end would be taken with the fall of the voluntary hospitals.

Mr. Arthur Greenwood (Minister of Health), in responding, said that the view that the Ministry of Health had no regard for the voluntary hospital system of this country was utterly mistaken. From two points of view, the voluntary hospital system in this country was vital to the progress of public health. First, it was interwoven with the growth of knowledge on problems affecting the lives of our people; secondly, there was need of every hospital bed existing in this country. His only object was to form a great brotherhood of people who would serve the common ends of humanity. In the effort to understand the problems which doctors felt were fundamental in the public interest, he had gathered to himself the heads of the profession, in a spirit of friendship, and the response had been whole-hearted. He was appalled, as he dug deeper and deeper into the problems of public health, by our lack of knowledge, which only the medical profession could remedy. There remained much to be learned, and, when it had been learned, much to be applied. He welcomed, without reservation, the fullest coöperation of the medical profession, and would do all in his power to help that profession in its work. He asked—was entitled to ask—the members of the profession that they in their turn would assist His Majesty's Government, and would believe that the Government was as much concerned with the problems at issue as medical men were themselves, because they had got to face the results of lack of knowledge. He hoped that, as this Government grew from strength to strength, and as it was succeeded by others of similar intensity of purpose, the bond between this great profession and the Government would also grow from strength to strength. He claimed the assistance of the profession that there might issue a magnificent people, people of fine calibre and tremendous spirit, a body of citizens which would lead the world.

Mr. H. P. Macmillan, K.C., expressed his conviction of the great mutual benefit which results from association with members of other professions. Professional men were apt to get into ruts—and a rut, as had been happily said, only differed from a grave in being narrower. Sir Alfred Ewing had once suggested that we all needed "re-potting" at intervals. We got pot-bound in our professional routine, and an occasional transplantation into fresh soil was wonderfully reviving. It was only within the last hundred years that medicine, like law, had finally emerged from the fogs of mediæval mysticism. The earlier London pharmacopœias read like inventories of an alchemist's spells and potions. Even in 1824, neither morphia, iodine, nor quinine was to be found in the official Pharmacopœia. The great strides recently made in the direction of preventive medicine in the department of public health emphasised the fact that in the treatment of mental disorder alone the public was still excluded by an antiquated system from the benefit of preventive treatment. Mr. Macmillan hoped that this restriction would soon be removed. To the need for preserving the voluntary hospitals system, the Minister of Health had referred with a fitting emotion. All would rejoice that the Minister recognised the value of these institutions, and that apprehension of peril to them was not likely to be realised under his guidance.

SOUTHPORT HOMŒOPATHIC HOSPITAL.—This hospital has been purchased for £3500 by the Southport Town Council. It is in future to be used for the treatment of aged and infirm patients.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Critical Condition of the Medical Profession.

Prof. Schlossmann, of Düsseldorf, lately read a paper before the German Society for Social Hygiene on the crisis in our profession. The liberty of the medical man, he said, is a dream of days gone by and the profession cannot longer resist a progressive nationalisation. Apart from some specialists with a large income the majority of doctors earn their livelihood from the fees paid them from institutions under the State Insurance Act. This Act provides them with 250,000,000 marks every year. Moreover, the individual practitioner has to observe so many rules and regulations issued by the government and by insurance authorities that he cannot be described as a free worker. Prof. Schlossmann does not at all agree with the leaders of the profession in their fight against sick clubs and other institutions of State insurance, for he holds that it only embitters their mutual relations. It would be better, he thinks, to coöperate with them so as to get over certain abuses.

According to Prof. Schlossmann, the profession is suffering from an economic crisis, an ethical crisis, and a crisis of confidence. The position of the younger generation who have to wait several years before admission to club practice is desperate financially, but still worse is the fact that they are obliged to be without work at a time when it is most desirable that they should be gaining experience and consolidating what they have learnt. The present method of study does not create medical practitioners; two years are spent in learning chemistry, physics, botany, zoology, physiology, and anatomy, and during this time the medical student does not see a single patient. Furthermore, clinical teaching is much too theoretical. What is worst of all is the public lack of confidence in doctors. The Insurance Act leads the patient to look upon the practitioner as more of a sick club officer than a medical adviser. Medicine has changed from an empirical to a technical science. The individual practitioner is not in a position to know all the technical methods of treatment and still less to provide for himself all the technical apparatus; this is the reason why patients are often sent to dispensaries, hospitals, and clinics, which have modern equipment. The increasing number of unqualified persons and the afflux of patients towards them bear further witness to the critical state of the profession.

Prof. Schlossmann suggests not that social insurance should be limited but rather that it should be extended. The object of sick clubs should be not only to cure their members but also to keep them in good health. If this were done, and if those classes of the population who are still outside national insurance were admitted to its benefits, a great number of the profession would find employment. His address has created a sensation, for he is a man who is well known in his specialty and also as president of the successful exhibition of hygiene held in Düsseldorf in 1926. The *Ärztliche Vereinsblatt*, the official organ of the Vereinsbund, says that his opinion that the representatives of the profession are hostile to State insurance is absolutely erroneous. But the medical profession, it continues, wishes to remain a free profession whose rights and duties as to insurance practice are limited by free agreement, and it is not inclined to become a mere collection of insurance employees.

Treatment of Congenital Dislocation of Hip-joint.

The German Congress of Orthopædics discussed the results of the treatment of congenital dislocation of the hip-joint. Prof. Lange, of Munich, reported the results obtained by the bloodless method of Lorenz which has been generally adopted for 30 years. At Munich and elsewhere, he said, he had studied the results of 2200 cases in which the reduction was performed between 3 and 25 years ago. Only in 5 per cent. had reduction proved impossible, but the difficulty was to retain the reduced joint in position, especially after the dressing had been removed. Redislocation may take place and sometimes a deforming arthritis or coxa vara may develop in the course of years. In 50 per cent. a full anatomical and functional cure was obtained, but to get this result the children had to remain under care for several years. Functional troubles rarely developed in cases where the deformity was reduced within the first two years, and the moral was that this should be done as early as possible. Dr. Spitzy, of Vienna, described a method of producing an acetabulum in cases where the reduction had been only temporarily effective. He makes the joint accessible without opening it and drives a splint, taken from the tibia, into the region above the head of femur. In this way an impediment to dislocation is provided. He has operated on 15 cases with good results.

Abandonment of a Medical Qualification.

The question whether a medical man may renounce his qualification has lately been decided by the Bavarian High Court. A doctor was being prosecuted for a crime, and, expecting to be sentenced to imprisonment and loss of civil rights, which includes the loss of the qualification, he informed the Government that he wished to renounce his qualification. Nevertheless, after being discharged from prison, he continued to describe himself in his prescriptions and on his door-plate as a qualified medical man, and was therefore prosecuted for wrongfully assuming that title and making the public believe that he was duly qualified. In the trial he pleaded that his letter to the Government had been voluntary, that he had not been deprived of the right to revoke it, and that he thus had the right of describing himself as qualified. The supreme court, however, found him guilty. It held that a medical man has the right to renounce his qualification, but only on condition that he does not intend to use it again. The defendant had been punished for his crime with the loss of civil rights which include the qualification; if he wished to regain it he would have to petition the Government for an act of grace.

Leaf Silver as a Dressing for Wounds.

Dr. Moritsch recommends leaf silver as a covering for fresh injuries, wounds, excoriations, and bruises. This material has been used by Prof. Lexer, of Munich, to cover sutures in plastic and cosmetic operations. Moritsch has noticed that under the silver leaf the wounds become cleaner and the discharge is less than under the usual ointment dressing, also the change of dressing is less painful. Owing to the bactericidal action of leaf silver the sutures may be left longer in the wound, which is of special importance with wounds under a plaster-of-Paris dressing.

Gonococcal Meningitis.

Dr. Lorentz has recently observed in the Berlin Westend Hospital a case of gonococcal meningitis. Such cases are very rare and it has seldom been demonstrable that meningitis occurring during gonorrhœa was due to the infection. In the case under his care the gonorrhœa was complicated by arthritis. The organism cultivated from the cerebro-spinal fluid was shown to be Neisser's gonococcus by microscopical, biological, and serological examination.

An international exhibition of hygiene is to be held in Dresden. It is the purpose of the exhibition to instruct the public in health matters and to give a full picture of what has been done in this direction. Whereas the exhibition of Düsseldorf was universal and included every branch of hygiene, social medicine, and gymnastics, the Dresden exhibition will be limited to personal hygiene. It is expected that the German States and Provinces, and all the bodies concerned in health, will take part, as they did in the last Dresden exhibition in 1911. Foreign countries have shown great interest in the exhibition and several governments have already declared their readiness to contribute.

In the past year 100,000 former combatants have made claims for the first time for damage done to their health by the war. In the past nine years 2½ million certificates have been given under the law for the care of the victims; 900,000 combatants receive pensions; and there are 100 offices for the care of the injured, with 500 full-time medical officers.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Clemenceau.

THE medical profession in Paris claims the great patriot as one of themselves. Georges Eugène Benjamin Clemenceau was born in 1841 at Mouilleron-en-Pareds in the Vendée, was educated at the Lycée of Nantes, and became a docteur-en-médecine. Migrating to the United States in 1865 he returned to Paris in 1870 and practised as a physician in Montmartre before he was elected mayor of the eighteenth arrondissement and a member of the National Assembly.

X Rays and Neighbourliness.

Some time back one of the great Paris dailies foreboded all sorts of troubles for the unhappy people who live in the neighbourhood of X ray installations. It was not the first time that Mr. Coutremoulins, the distinguished physicist, obtained a hearing for some of his ideas in the lay press and in official circles. Mr. Coutremoulins was one of the X ray pioneers in this country, and though he is no physician he is still at the head of the Rontgen service at the Necker. Much sensation was caused by his discovery that a photographic film is affected by the rays from a tube 100 yards away. In his experiments it was, of course, a naked tube. Mr. Coutremoulins draws the deduction that X ray installations are dangerous for the neighbourhood. Most of his medical friends would say: No, not if the tubes are protected. But their evidence is held to be biased because it is in their own interest to minimise the risk. Some years ago the Académie des Sciences of Paris appointed a special committee to study the question, and its answer was that in actual X ray work no danger exists for neighbours. Now a committee has been appointed by the préfet of police, of which Mr. Coutremoulins is a member. It is somewhat remarkable that with the exception of Dr. Zimmern and Dr. Lobligeois no other member of the committee has special knowledge of X rays. So everyone wonders what authority its decisions will have.

The Confédération des Syndicats Médicaux has sent to every member of both Chambers, senators and deputies, a formal letter containing the solemn decision of the medical profession to refuse collaboration if the social insurance law is not modified. Amendment is indeed probable, but when? The law is due to come into force on Feb. 5th. The budget discussion is only just started and will scarcely be finished by the New Year. Then come the holidays, which are sacrosanct, and January will be over.

Prof. Netter, of the Institut Pasteur, has given the Académie de Médecine his views on the ætiology of post-vaccinal encephalitis as a result of his study of a campaign of vaccination at Rotterdam. He lays the responsibility on the preparation of vaccine lymph by passage through the rabbit.

César Roux, professor of surgery in the University of Lausanne, has been awarded the diploma of doctor hon. caus. of the University of Paris. The same distinction has been granted to Dr. Egas Moniz, of Lisbon, the originator of arteriography by injection of sodium iodide, by the University of Lyon.

LONDON CLINIC AND NURSING HOME.

THE ceremony of laying the foundation-stone by the Duchess of Atholl of the London Clinic and Nursing Home, Limited, was held at the Devonshire-place entrance of the building now rapidly rising at the corner of Devonshire-place and the Marylebone-road.[1]

After the ceremony the Chairman and Directors entertained a large number of supporters and friends at luncheon at the Trocadero Restaurant, Piccadilly, when the Duke of Atholl presided.

After luncheon and the loyal toasts, Lord Moynihan, President of the Royal College of Surgeons of England, proposed Prosperity to the Scheme, which he referred to as a necessary development of modern medicine. He pointed out that, while the art of the Middle Ages still left us marvelling, the progress of science, especially in relation to medicine, during the last fifty years at any rate, had developed in an unlimited manner. Lister had ensured, he said, that a large range of cases previously termed medical should pass to the sphere of surgery, while operative surgery meant the institution of nursing homes. The scheme whose prosperity he was advocating he described as the first concerted effort to supply in London a nursing home where not only accommodation but specialised service could be obtained, with the important additions of resident medical officers, adequate nursing, and direct provision for the association of the general practitioner with the cases. Alluding to the financial support from laymen, which had made the scheme possible, he said that, while pecuniary dividends might be absent, dividends in terms of moral worth would be credited to them by the Recording Angel. In wishing heartily for the success of the scheme, he warned its supporters that criticism was ahead of them on the grounds either of their motives or of the practical nature of their plans, but that criticism, he had found, was a proof of success.

Mr. Allan Hepworth, the Managing Director, said: The ceremony we have witnessed to-day marks a further stage in the development of a scheme upon which certain doctors and laymen have been working for some few years, and which, when carried into full effect, should have far-reaching and beneficial results for paying patients, especially those of moderate means. So far as these patients are concerned there is a pressing need for provision more adequate in quantity and quality and more in harmony with present-day demands. We are not overlooking the increasing effort now being made by many of the hospitals for providing pay-beds, but only a limited number of these can occur—that is to say, that certain patients availing themselves of the service of the hospitals and being in a sufficiently satisfactory financial position are expected to pay. But when the hospitals have extended to this class the fullest provision they can, there will still remain a large section of the public demanding such a service, and on such reasonable terms and conditions as our clinic and nursing home will make an effort to furnish. We believe there is a great opening, not only in London, but also in the provinces, for many such clinics and nursing homes as the one we are now establishing, for already our scheme, and the ideals governing its working, have created widespread interest, and in two or three of our largest provincial cities a similar project is under consideration.

The advancement of our scheme has necessarily called forth criticism, favourable and adverse; we welcome both, especially adverse criticism, when it is constructive and well informed. Both on the medical and the business side we have for a long time been convinced, from facts, experience, and requirements, that there is a pressing need for a clinic and nursing home governed by the ideals, and with such service and administration as we are adopting; it is our intention to open out a wide field of valuable service for the benefit of sick people, and if this may mean the breaking down of some of the old fences, we hope to replace these with something better and more in harmony with present-day necessities.

Dr. Moreland McCrea, Chairman of the Medical Group, who also responds to this toast, will explain the position of the doctors identified with the Clinic. As Managing Director I will refer to the financial, administrative, and service side of the nursing home. Whilst the responsibility for the management of the home will rest upon the Directors of the Company, there will always be the closest coöperation with the Medical Group, and between the two there is a complete unity of views. In all our long deliberations goodwill and perfect understanding have prevailed. May I emphasise the point that this nursing home is not a hospital, it will not be administered on the usual hospital lines, and we shall in no way attempt to compete with the hospitals. Our nursing home can perhaps be better described as an hotel for sick people—that is to say, it will be directed more on the lines of hotel than a hospital, or than many existing nursing homes—especially as regards the freedom of the patients and the facilities for visiting by relatives and friends.

With reference to the financial side of the Nursing Home scheme, may I first publicly express appreciation of the services rendered by certain gentlemen in the City of London, who being actuated by a true public spirit, and considering the establishing of this nursing home a matter of great public importance, not only subscribed themselves for a large amount of the capital, but influenced other shareholders to subscribe. Without this valuable help the necessary capital would not have been obtained. It is a great pleasure to be in a position to state that the necessary capital has been found, and that our financial resources enable the Company to complete, furnish, and equip the building while retaining a working capital equal to our requirements. The Clinic and Nursing Home is a public limited company, the shares being held by about 800 shareholders, but the Company has not been brought out as primarily a money-making concern. Those in the City who were responsible for finding a large amount of the capital did not put up their money with the object of making it a remunerative financial operation, but are prepared to sacrifice their own financial interests for the sake of what they consider an important and much-needed public movement. None of them hope or expect to make money out of it. Notwithstanding this fine and magnanimous public spirit, the Directors of the Company recognise that there are two interests to look after: (1) the shareholders as investors in the Company, and (2) the patients. We are convinced we can serve the interests of both when the detailed plans and arrangements, carefully thought out, are put into operation. We expect to give the shareholders a reasonable return on their investment, whilst for the patients there will be a nursing home and a medical service which for efficiency, comfort, satisfaction, and reasonable charges will certainly not be *surpassed by any first-class nursing home* in London.

With regard to the charges for the various patients' rooms and the service, patients will have an alternative choice as to which they will be asked to pay: (1) a fixed price for the room, plus what are understood to be charges for the usual extras, and our charges for such extras will be based on an exceptionally moderate scale; or (2) an all-inclusive price (*a*) for the room, (*b*) fee for operating theatre, (*c*) dressings, (*d*) drugs, (*e*) special nurses if required,

---

[1] THE LANCET, 1928, ii., 720.

The patients will thus know, before they enter the Home, the exact cost of their stay per week, with no bill for extras on leaving. It is expected that the nursing home will contain about 200 patients' bedrooms, and each room has received careful consideration in the matters of lighting, heating, ventilation, and equipment. Representatives of the Medical Group, and the Directors of the Company, including the Architect, Mr. Biddulph-Pinchard, have visited numerous clinics, hospitals, and nursing homes in Sweden, Denmark, Holland, France, and also in this country to find the latest and best of everything for the good of the home in general and the patients, nursing and other staff in particular.

In harmony with the statement published in the prospectus issued to the shareholders last April, certain provision will be made for a number of rooms for people of moderate means. The *non-inclusive* charges for the more well-to-do patients will range from about £12 12*s*. or £14 14*s* a week, and up to about 30 and 35 guineas a week, and for this larger amount a patient will be provided with a private suite of rooms, so that if any relative desires to stay, or live in the home for a time with a patient, this can be arranged. Where an *all inclusive* charge per room is desired these prices will, of course, be increased.

The most careful attention is being given, by the Management Board and the Medical Group, to the service in the home. The choice and variety of the food to be provided, and its proper cooking and serving will be entrusted to members of the management whose technical skill, ability, and wide experience justifies full confidence, and as to the proper cooking we have already secured on our executive staff certain ladies of recognised standing in household and domestic science, with a wide range of practical experience in dietetics to meet the needs of any patients who are ordered special diets by their medical advisers. We shall also engage experienced chefs, and in making these appointments we have already been promised the help and advice of certain friends of our nursing home who are in a position to give practical effect to their advice. In fact these friends have promised to procure them for us.

It remains to refer to the appointment of the matron and the selection of nurses. As to the appointment of matron we shall have a wide choice, for already we have received applications from many candidates. With regard to the nursing staff, of a total number well over 120, we think there is need to strike out on new and better lines to secure the best and most experienced nurses for whom there will be a hostel in a suburb within a reasonable distance of the home. In the general running of the hostel we shall aim at making the nurses comfortable and creating such an atmosphere as will make it less of the usual institution and more of a home from home.

In Greater London we have a population of 8 to 10 millions of people constantly swelled from the provinces and by foreign visitors; with the resources to draw upon, which I have mentioned, we think that the service we shall provide will command success.

I thank you, Lord Moynihan, on behalf of the Company and the Medical Group for the toast you have so kindly and gracefully proposed, and to you, my Lords, Ladies, and Gentlemen, for the way you received the toast.

Dr. Moreland McCrea, Chairman of the Medical Group, said: It is a curious fact that while we have in London establishments unsurpassed in the world in efficiency and comfort for the treatment of the sick poor, no such provision has been made for those who are able to pay for treatment, though the latter provide the necessary funds. However creditable it may be to our charitable instincts that we provide in our hospitals, as a free gift, every resource that modern methods can devise for the investigation and treatment of disease, it is scarcely a tribute to our common sense that we exclude all but the objects of benevolence from these very resources. With the advance of medical science there has arisen a demand for an elaborate equipment which can scarcely be provided by individuals, and for a coöperation, never thought of in the older methods of practice, between specialists in different branches. The introduction of such an equipment and coöperation into private practice is everywhere recognised as imperative to practical progress. It is just ten years since some of us met to discuss this difficult problem. The obvious answer was to erect a building fully equipped for the investigation and treatment of disease, on the lines of a modern hospital, with rooms to suit the means of all classes of paying patients, and with adequate laboratories. If to such a building there could be attached a block of consulting-rooms occupied by consultants representing every branch of medicine and surgery we felt that an ideal solution would be obtained. We imagined that we had only to give to a cause so meritorious our blessing for the financiers in the City of London to open their coffers and supply the necessary funds. We were, however, soon disillusioned. No matter how meritorious our scheme the City would not take us on trust, and we found that it was useless to expect their help unless we were prepared to take some financial risk in the undertaking. As this was contrary to all medical ethics in this country our negotiations came to an end.

The fact that we are to-day in a more fortunate position is due to the enlightened enterprise of a distinguished group of business men, who have been able to grasp both the importance of our objects and the difficulty of our professional position. They have generously taken upon their shoulders the whole financial responsibility of the undertaking, only asking us to take the 99 years' lease of the block of 36 consulting-rooms in a building closely adjoining the nursing home. To them we owe the fact that our dreams are about to be realised and that we shall shortly see in actual being the great building of which your Grace has to-day so kindly laid the foundation-stone. The statement I have just made concerning the financial position represents the only monetary transaction undertaken by members of the Medical Group. They have also agreed to supply a committee to work in an honorary and advisory capacity with the Company, in a similar manner to the medical committee of all our large hospitals.

Speaking for the benefit of those who are unable to be present at to-day's ceremony, I may say that the site chosen for the building is situated on the south side of the Marylebone-road, and is bounded on the west by Devonshire-place and on the east by Harley-street. We have been asked why such a site should have been chosen in preference to one further afield, and we have been told that in such a position it will be impossible to eliminate noise. But a site in the chosen neighbourhood was essential, and we are satisfied that the rooms occupied by patients will be quiet and free from disturbance. These rooms will face not on the Marylebone-road, but on the south, south-east, and south-west frontages. The rooms facing on the Marylebone-road will be used for administrative purposes. Between the latter and the former there will be a long corridor 10 feet wide, and in this way the patients' rooms will be entirely protected from the noise of traffic. The goods entrances, including that for milk, will be on the Marylebone-road side. To secure privacy for the admission of patients by ambulance a special entrance has been arranged on the south side. The entrance of the nursing home will be in Devonshire-place.

The building will contain 200 beds. It has been designed with the utmost care, after literally years of study, by an architect who is unique in the attention which he has devoted to this particular problem, in constant consultation with the Medical Group and with the directors of the company. In order to obtain the very latest information on modern hospital practice, a committee of the directors and the members of the medical group has visited the most modern hospitals in Sweden, Denmark, Holland, and France, and we are convinced that this hospital will set an entirely new standard in design and equipment. A wide range of accommodation between small single rooms and large suites will meet the varying requirements of patients, but in every single instance the standard of comfort will be the highest attainable, and special attention has been paid to small amenities. Two features in the staffing of the hospital will add greatly to the comfort of the patient. The nursing staff will be sufficiently large to enable us to supply special nurses, usually a costly item, at a very low charge, and there will be two resident medical officers who can be called upon at any moment of emergency. In regard to the latter we desire it to be clearly understood that these resident medical officers will in no way usurp the authority of the patient's own medical adviser. It is an essential part of our conception that the patient should still remain in contact with his regular medical adviser, for we consider this of the utmost importance for the continuity of treatment.

The hospital will be open to the patients of any medical man whose name is on the Register of the General Medical Council, but it will be appreciated that the Group must have the first call upon empty beds. Should consultation be required, there will be the perfect freedom of choice which exists elsewhere to-day. The laboratories, X ray department, and dispensary, all of the highest class, will be at the service of all surgeons, physicians, and general practitioners who have patients in the hospital, on an equal footing with the members of the Group. The occupants of the consulting-rooms will see all their patients on the usual basis of individual practice, having the advantage of proximity to the hospital, its X ray equipment, and its laboratories. There is no moral, legal, or verbal agreement in existence or contemplated for any tenant to employ in a consultative capacity any other tenant in the building. There will be absolute freedom of choice in every respect as it exists to-day. A plan is under consideration by which the combined efforts of these tenants can be placed at the disposal of the medical profession for that large class of patients which is just outside the limit for receiving hospital benefits. The Company have agreed to place at our disposal some beds for this purpose at a low figure. It would be possible to arrange a composite fee in order to include all form of examination and treatment for these patients, and in this way all the advantages of combined work could be brought within the reach of a large deserving class of patients.

Such, Your Graces, My Lords, Ladies and Gentlemen, is our policy and our scheme. May your good wishes be fulfilled, and on behalf of the Group I thank you.

"The health of the Duchess of Atholl" was proposed by Sir Lenthal Cheatle, and was drunk with acclamation, after which Mr. B. H. Binder proposed the toast of "The Guests," to which Lord Greenwood replied. The proceedings closed with a toast proposed by Dr. Beddard, wishing prosperity to the Chairman of the scheme.

SECOND INTERNATIONAL MALARIA CONGRESS.

IN 1925 a committee of Italian malariologists including Drs. Marchiafava, Ascoli, Bignami, Bastianelli, Dionisi, and Gosio, initiated and organised a "*First International Malaria Congress*" which was held at Rome in October of that year under the patronage of the Italian Government. One of the resolutions passed was that there should be a second International Congress in 1930, which would be the fiftieth anniversary of Laveran's discovery of the malaria parasite, and that it should be at Algiers, where the discovery was made. Arrangements for this Congress have now been completed under the authority and patronage of the French Government. It will be held at Algiers from May 19th to 21st, with Prof. Mesnil as president. The following subjects will be discussed: (1) the parasitology of malaria (including therapeutic malaria from the parasitological point of view), (2) anopheles mosquitoes, (3) epidemiology and endemiology, (4) pathology, (5) quinine and other alkaloids and drugs in therapy, and (6) prevention and control. Communications should be in English or French and should be sent so as to arrive at the general secretariat of the Congress (Pasteur Institute, Algiers) before Dec. 31st. They will be printed and distributed to members before the opening of the Congress. Members of the Congress will include, in addition to representatives of Governments and institutions, all medical men, biologists, biochemists, and engineers who desire to participate. Applications for membership of the Congress should be sent before Jan. 15th, 1930, to the secretary-general of the Congress (Dr. L. Parrot, Pasteur Institute, Algiers, Algeria), accompanied by a postal order for 100 French francs. This subscription will entitle the member to take part in all meetings and official receptions of the Congress, to receive a printed copy of the Transactions, and to benefit by the reduction of fares allowed by the French railways and shipping companies. There will be optional excursions on May 22nd, 23rd, and 24th.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. M. Gordon is placed on the Retd. List with rank of Surg. Capt.

Surg. Lt.-Comdrs. F. L. H. MacDowel and A. W. McRorie to be Surg. Comdrs.

The following appointment is notified: Surg.-Lt. T. W. Froggatt to *Devonshire*.

ROYAL ARMY MEDICAL CORPS.

Lt. A. T. H. Marsden is secd. for serv. with the Sudan Def. Force.

ARMY DENTAL CORPS.

Capt. D. H. W. Williamson to be Maj.

Lt. J. J. Seaton to be Capt.

ARMY RESERVE OF OFFICERS.

Lt.-Col. G. J. S. Archer, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

SUPPLEMENTARY RESERVE OF OFFICERS.

G. F. Walker to be Lt.

TERRITORIAL FORCE.

Lt.-Col. F. G. Lescher to be Bt. Col.

Maj. D. S. Martin, R.A.M.C., to be Divl. Adjt. 46th (N. Midland) Div.

Maj. W. C. MacKinnon, R.A.M.C., to be Divl. Adjt. 50th (Northumbrian) Div.

Capt. J. D. Hart to be Maj.

D. M. Dunlop to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capts. A. N. Smith, H. Miller, and H. S. Allen, from Active List (supern. for serv. with O.T.C.), to be Capts.

ROYAL AIR FORCE.

The undermentioned Flying Officers are promoted to the rank of Flight Lt.: D. A. Wilson, F. E. Lipscomb, M. Clancy, C. P. O'Toole, G. H. J. Williams, S. B. S. Smith, V. V. Brown, J. F. McGovern, and W. Heron.

Lt. C. M. Leckie (General List, Army, Dental Surgeon) is granted a temporary commission as a Flying Officer (Dental) on attachment to the R.A.F.

Capt. R. E. Edwards (Army Dental Corps) is granted a temporary commission as a Flight Lt. (Dental) on attachment to the R.A.F.

Flight Lt. P. P. Hogan (Capt. Army Dental Corps) relinquishes his temporary commission on return to Army duty.

INDIAN MEDICAL SERVICE.

Capt. Ajab Singh Garewal to be Maj.

The probationary appts. of the undermentioned officers are confirmed:—To be Capt.: S. Hartley. To be Lts.: J. Acheson (now provl. Capt.), K. H. A. Gross, Shankar Sahai Bhatnagar, Bijeta Chaudhuri, E. V. Claydon, C. F. J. Cropper, V. H. Sarland, J. P. J. Little, E. A. O'Connor, and P. L. O'Neill.

Obituary.

LAURENCE BALL, M.C., M.D., F.R.C.P. Lond.

We regret to announce the death of Prof. Laurence Ball, which occurred at his consulting-rooms in Birmingham on Nov. 20th from an attack of angina pectoris which was the first and only manifestation of any cardiac disease.

DR. LAURENCE BALL.

[*Photograph by Whitlock.*

Laurence Ball was born in Birmingham in 1884, his father being an architect in that city. He received his medical education at the University of Birmingham, and in 1907 graduated in Medicine in the University of London, where he later secured the gold medal in the examination for the M.D. After holding resident appointments, both medical and surgical, at the Birmingham and Midland Hospital for Sick Children, he served for a year as house physician at the Queen's Hospital, and for another year as resident medical officer at the General Hospital. He then went to London for post-graduate study in medicine, and took the diploma of M.R.C.P. in 1911. Not long afterwards he was appointed pathologist and assistant physician to the Queen's Hospital, where, in 1926, he became full physician. At the time of his death he was also physician to the Children's Hospital and to the Birmingham and Midland Hospital for Diseases of the Nervous System. At one time he was lecturer in pathology in the University, and in 1926 he was appointed joint professor of medicine. Two years later he was elected a Fellow of the Royal College of Physicians of London.

Dr. Ball took a keen interest in pathology, and his sound practical knowledge in this department was often of great benefit to his colleagues. He was also much interested in medico-legal matters. Mr. Bertram Lloyd, to whom we are indebted for biographical details, says of him that he "was throughout devoted to his work, and took the greatest delight in it. The freshness and enthusiasm with which he would enter into the consideration of a knotty case or medico-legal problem was a constant source of stimulation to his colleagues. Although a very busy physician, he could always find time for another duty, and never appeared to be in a hurry. His patients had an affection for him which it is difficult adequately to describe. His professional manner inspired at once confidence, respect, and admiration for his wise judgment. Although much in request as a physician, it was as a teacher in the Medical School that he was pre-eminent. An eloquent speaker and a lucid teacher, his knowledge never seemed to fail him on any point. The students of the school crowded to his classes and held him in the highest regard. On personal grounds he was immensely popular. He was entirely devoid of vanity or affectation, and was possessed both of a deep fund and a keen appreciation of humour. Although temperamentally of a quiet and studious nature, he was constantly sought after by colleagues and students because of his attractive personality."

Dr. T. L. Hardy writes: "May I add my tribute to the memory of Laurence Ball, whose untimely death has removed from the ranks of the profession a sound physician and teacher of medicine, and a most lovable personality. I have enjoyed the privilege of his friendship for a matter of ten years, time enough in which to appreciate his many sterling qualities, for he combined in rare measure great modesty, charm of manner, and a love of the beautiful things in life and no less of its simple pleasures. He had a great capacity for friendship, a generous tolerance of the shortcomings of others, and he spoke ill of no man.

"Ball was a man of retiring disposition, rarely obtruding his opinions, but never failing those—and they were many—who sought them... He undoubtedly enjoyed life to the full, loving especially the big open spaces, and was never so content as when tramping among the hills of Cumberland or Wales with his friends. On such holidays his companionship was a thing of delight, for he was a man of wide culture and could talk with learning on many topics. He was, too, an amateur photographer of distinction, and his keen sense of beauty resulted in work of very high artistic merit. With children he possessed something akin to genius, and the joy his company brought to many families is a thing not easily forgotten.

"Ball contributed but little to medical literature and to research, holding the view that these things interfered with the proper discharge of his teaching duties, and it was to these that his energies were mainly devoted during the all too brief span of life allotted to him. As a teacher he was outstanding, whether in the lecture theatre, at the bedside, or in the post-mortem room, while his presentation of a case at a medical society was a model of lucid exposition. He was no specialist, indeed he heartily disliked the term, but was possessed of a wide knowledge of medicine in all its branches, knowledge which had been built up during many years in the post-mortem room. He was in the fullest sense of the term a general physician possessed of a maturity of judgment remarkable for one of his years. Yet though he has been taken at the outset of a brilliant career and has left behind him no written record of endeavour, his memory will endure in the hearts of his many friends, the students he loved to teach, and the patients, old and young, whom he delighted to serve."

In the course of service abroad in France and Italy during almost the whole of the late war, Dr. Ball was awarded the Military Cross, and was mentioned in General Plumer's dispatches for gallant and distinguished service in the field. He was unmarried, and is survived by his father.

Tenbury Cottage Hospital.—This institution, founded in 1867, has been closed, and the building, which is expected to produce £1000, is to be sold. A committee has been appointed to consider the application of this sum and the £2000 of invested funds with a recommendation to give preference to home nursing purposes. The reason assigned for the closing of the hospital is the reduction in the number of patients caused by the introduction of the Worcester Hospital Contributory Scheme.

Queen Mary's Hospital for the East End.—There was an unusual incident at the annual festival dinner of this hospital at which the Duke of Gloucester presided last week. It was desired to raise £10,500, and the donations announced amounted to £10,478. It was suggested that two of the guests should toss for the privilege of providing the balance of £22. The Lord Mayor and Sir Leonard Lyle, the chairman of the hospital, tossed for £10 and the Lord Mayor lost. The Duke of Gloucester and Sir Leonard then tossed for the remaining £12, and the Duke had to pay.

"Audi alteram partem."

MALARIA TREATMENT OF GENERAL PARALYSIS.

To the Editor of THE LANCET.

SIR,—Before the introduction of Wagner von Jauregg's treatment of general paralysis a terminal stage of this disease, characterised by extreme emaciation in spite of adequate nourishment, was common. I have seen as many as four cases exhibiting this condition in bed in hospital at one time. Kraepelin attributed the condition to endocrine disturbance. Reichardt is more definite and attributes it to a specific degeneration in the vegetative trophic centres in the hypothalamic region. It is our experience at Whittingham that this "conspicuous body-wasting termination" of general paralysis never occurs following malaria treatment. In the mass of medical literature on this subject I do not find this fact mentioned, and think our experience worth recording as it may, or may not, be confirmed, and the observation may help to explain the mode of action of malarial therapy concerning which so many theories have been advanced.

I am, Sir, yours faithfully,

R. M. CLARK.

Whittingham Mental Hospital, Lancashire, Nov. 25th, 1929.

ROSS AWARD FUND.

To the Editor of THE LANCET.

SIR,—Those of your readers who have subscribed to the Ross Award Fund will be interested to hear that the officer commanding the First Battalion, the Sikh Regiment at Razmak, Waziristan, India, has kindly sent a cheque for £15 towards the Fund, the amount having been chiefly subscribed by the men of that Battalion who willingly gave it from their pay (which is scarcely large). The O.C. goes on to explain that this fund is of particular interest to the Battalion because not only did Sir Ronald's father—General Sir Campbell Ross—command the Battalion as Colonel, when it was known as the 14th Sikhs, when Sir Ronald was born in India, but also Sir Ronald's brother—Captain C. Ross—was killed while serving with this Battalion in connexion with the Chitral Campaign. This Sikh Corps has been always celebrated as an extremely fine body of men who have faithfully helped this country in many campaigns.

Your readers will be further interested to know that the Fund has now reached £10,010 3s. 7d., of which the *Straits Times*, Singapore, have contributed £3302 19s. 10d., and the *Malayan Daily Express* Fund £75 15s. 4d. Donations should be sent to Lloyds Bank, Ltd., 110, High-street, Putney, S.W.15.

I am, Sir, yours faithfully,

JAMES BARR,

Chairman of the Ross Award Fund Committee.

Hindhead, Surrey, Nov. 24th, 1929.

THE ROYAL FREE HOSPITAL V.D. CLINIC.

To the Editor of THE LANCET.

SIR,—An annotation in your issue of Nov. 16th (p. 1053) speaks of the Royal Free Hospital Female V.D. Clinic as dealing with a considerable number of prostitutes. This belief about the Clinic is fairly widespread, I have met it in one quarter and another during the past five years, and it is quite wrong. If we can be said to specialise in any type of case, it is that of the unmarried mother, infected or probably infected, and for this reason referred to us by various social workers and philanthropic agencies from all parts of the country. The overwhelming majority of such cases are servants, domestic or hotel, and waitresses, and one of the rules of our hostels to which such cases are admitted is: "Save under exceptional circumstances remand cases or prostitutes are not suitable for admission to these hostels"—this for the guidance of social workers sending up cases.

We have, of course, a very considerable family attendance of married women and their children and a special clinic is held on Wednesdays from 2 to 4 P.M. for doctors' cases referred particularly to myself. During these hours married women only are seen. This is *not* to prevent their mixing with prostitutes, as may be suggested, but so that they may not be kept waiting on their first visit, especially as many of these are pregnant or recently delivered.

I apologise for intruding on your valuable space but must endeavour to remove this misconception, lest doctors fear to refer married women and children to the department in case they be offended by the type of patient waiting to be seen at the same time. There does not seem to be any V.D. clinic to which professional prostitutes go in any numbers. Whether this is because they have other arrangements or because, save in the richer circles of the demimonde who can, of course, afford private treatment, they are being ousted almost entirely by the amateur I do not know; but the fact remains that the professional prostitute is very rarely indeed met with in my clinic.—I am, Sir, yours faithfully,

MARGARET RORKE,

Director of the Female V.D. Department,
Royal Free Hospital.

Nov. 25th, 1929.

THE TEACHING OF RADIOLOGY.

To the Editor of THE LANCET.

SIR,—"Seeing is believing" is almost a fetish among Americans; they are always seeking means of visualising disease. In England we rely almost exclusively on clinical methods, employing such a magnificent aid to vision as radiology only when destitute. The radiologist's or radiographer's task is to correlate, revise, and if necessary correct the clinical diagnosis in the *early* stages of disease.

Why does radiology persist in taking a back place here in England? Surely it is because the general practitioner has no means of learning what it will do that he does not seek its aid. For those specialising in the science there are excellent courses; these courses, like most text-books, deal chiefly with technique, which is just what the general practitioner does not want. There is a sharp distinction between those who know what radiology will do and those who can actually take the films. The most striking advances during the last ten years have not been by technicians but by clinicians with a knowledge of the capabilities of radiology; vide the use of lipiodol and sodium phenoliodophenolphthalein. One has only to scan the last few years LANCET's to realise what a price surgeons put on radiology. Morriston Davies's "Surgery of the Lung and Pleura" is essentially clinical but half the illustrations are radiograms demonstrating pathological processes; one can see the progress of a disease in these radiograms in a most beautiful manner. This is the "pathology of the living."

The British Institute of Radiology is the proper and obvious place for such lectures to post-graduates; it is doubtful whether the student should be burdened with more lectures. Half a dozen lectures are all that are necessary to learn the principles on which to build up one's knowledge. The Council of the Institute, however, are afraid that there would be a mushroom growth in the number of installations to the detriment of radiology. This need never happen, since technique need not and should not be mentioned. The word "technique" is a perfect bugbear to the general practitioner. It alarms and deters him; he imagines that all sorts of abstruse electrical problems beset him. Technique should and will always be left in the hands of those who are prepared to undergo the

Obituary.

LAURENCE BALL, *M.C.*, M.D., F.R.C.P. LOND.

WE regret to announce the death of Prof. Laurence Ball, which occurred at his consulting-rooms in Birmingham on Nov. 20th from an attack of angina pectoris which was the first and only manifestation of any cardiac disease.

Laurence Ball was born in Birmingham in 1884, his father being an architect in that city. He received his medical education at the University of Birmingham, and in 1907 graduated in Medicine in the University of London, where he later secured the gold medal in the examination for the M.D. After holding resident appointments, both medical and surgical, at the Birmingham and Midland Hospital for Sick Children, he served for a year as house physician at the Queen's Hospital, and for another year as resident medical officer at the General Hospital. He then went to London for post-graduate study in medicine, and took the diploma of M.R.C.P. in 1911. Not long afterwards he was appointed pathologist and assistant physician to the Queen's Hospital, where, in 1926, he became full physician. At the time of his death he was also physician to the Children's Hospital and to the Birmingham and Midland Hospital for Diseases of the Nervous System. At one time he was lecturer in pathology in the University, and in 1926 he was appointed joint professor of medicine. Two years later he was elected a Fellow of the Royal College of Physicians of London.

DR. LAURENCE BALL.

[*Photograph by Whitlock.*

Dr. Ball took a keen interest in pathology, and his sound practical knowledge in this department was often of great benefit to his colleagues. He was also much interested in medico-legal matters. Mr. Bertram Lloyd, to whom we are indebted for biographical details, says of him that he "was throughout devoted to his work, and took the greatest delight in it. The freshness and enthusiasm with which he would enter into the consideration of a knotty case or medico-legal problem was a constant source of stimulation to his colleagues. Although a very busy physician, he could always find time for another duty, and never appeared to be in a hurry. His patients had an affection for him which it is difficult adequately to describe. His professional manner inspired at once confidence, respect, and admiration for his wise judgment. Although much in request as a physician, it was as a teacher in the Medical School that he was pre-eminent. An eloquent speaker and a lucid teacher, his knowledge never seemed to fail him on any point. The students of the school crowded to his classes and held him in the highest regard. On personal grounds he was immensely popular. He was entirely devoid of vanity or affectation, and was possessed both of a deep fund *and a keen appreciation of humour. Although* temperamentally of a quiet and studious nature, he was constantly sought after by colleagues and students because of his attractive personality."

Dr. T. L. Hardy writes: "May I add my tribute to the memory of Laurence Ball, whose untimely death has removed from the ranks of the profession a sound physician and teacher of medicine, and a most lovable personality. I have enjoyed the privilege of his friendship for a matter of ten years, time enough in which to appreciate his many sterling qualities, for he combined in rare measure great modesty, charm of manner, and a love of the beautiful things in life and no less of its simple pleasures. He had a great capacity for friendship, a generous tolerance of the shortcomings of others, and he spoke ill of no man.

"Ball was a man of retiring disposition, rarely obtruding his opinions, but never failing those—and they were many—who sought them. . . He undoubtedly enjoyed life to the full, loving especially the big open spaces, and was never so content as when tramping among the hills of Cumberland or Wales with his friends. On such holidays his companionship was a thing of delight, for he was a man of wide culture and could talk with learning on many topics. He was, too, an amateur photographer of distinction, and his keen sense of beauty resulted in work of very high artistic merit. With children he possessed something akin to genius, and the joy his company brought to many families is a thing not easily forgotten.

"Ball contributed but little to medical literature and to research, holding the view that these things interfered with the proper discharge of his teaching duties, and it was to these that his energies were mainly devoted during the all too brief span of life allotted to him. As a teacher he was outstanding, whether in the lecture theatre, at the bedside, or in the post-mortem room, while his presentation of a case at a medical society was a model of lucid exposition. He was no specialist, indeed he heartily disliked the term, but was possessed of a wide knowledge of medicine in all its branches, knowledge which had been built up during many years in the post-mortem room. He was in the fullest sense of the term a general physician possessed of a *maturity of* judgment remarkable for one of his years. Yet though he has been taken at the outset of a brilliant career and has left behind him no written record of endeavour, his memory will endure in the hearts of his many friends, the students he loved to teach, and the patients, old and young, whom he delighted to serve."

In the course of service abroad in France and Italy during almost the whole of the late war, Dr. Ball was awarded the Military Cross, and was mentioned in General Plumer's dispatches for gallant and distinguished service in the field. He was unmarried, and is survived by his father.

TENBURY COTTAGE HOSPITAL.—This institution, founded in 1867, has been closed, and the building, which is expected to produce £1000, is to be sold. A committee has been appointed to consider the application of this sum and the £2000 of invested funds with a recommendation to give preference to home nursing purposes. The reason assigned for the closing of the hospital is the reduction in the number of patients caused by the introduction of the Worcester Hospital Contributory Scheme.

QUEEN MARY'S HOSPITAL FOR THE EAST END.—There was an unusual incident at the annual festival dinner of this hospital at which the Duke of Gloucester presided last week. It was desired to raise £10,500, and the donations announced amounted to £10,478. It was suggested that two of the guests should toss for the privilege of providing the balance of £22. The Lord Mayor and Sir Leonard Lyle, the chairman of the hospital, tossed for £10 and the Lord Mayor lost. The Duke of Gloucester and Sir Leonard then tossed for the remaining £12, and the Duke had to pay.

post-mortem examinations were made in 90·8 per cent. of cases. The death-rate from tuberculosis is 2 per cent. lower than it was in 1927, having come down to 6 per cent. The recovery-rate was 21 per cent., the lowest for many years. The medical superintendent attributes it to the large number of incurable patients admitted during the year. No less than 14 per cent. were idiots, imbeciles or epileptics. The number of patients usefully employed has been maintained, and the privilege of parole has been extended; a number of discharged patients were granted money allowances. There were three cases of typhoid and twelve of dysentery. General paralysis was treated with malaria for the first time last year, and six out of thirteen patients were improved, four being discharged. A visiting dentist has been appointed. All the patients admitted now have their blood examined by the Meinicke turbidity and Wassermann tests. The Meinicke reaction gave the same number of positive results as the Wassermann in 96 per cent. of cases, and seems to be a valuable auxiliary. The laboratory is now equipped to undertake all necessary investigations, and works in close correlation with the wards. During the year twelve attendants and nine nurses passed the final examination for the R.M.P.A. certificate. Of the present staff, 41 attendants and 21 nurses are certificated, and four attendants and five nurses are registered.

Wilts. County Mental Hospital.—There were 1146 patients on December 1st, 1928. The death-rate was 8·2 per cent. and the cause of death was verified by post-mortem examinations in 81·2 per cent. of cases. The recovery-rate was 25·8 per cent.; all but four patients discharged had a preliminary period of trial, 23 of them with a money allowance. The general health was good and there was no epidemic disease, but there were 23 cases of dysentery, one of paratyphoid B, and six of erysipelas. The out-patient clinics at Swindon and Trowbridge served 52 and 27 patients respectively. The housekeeper has had very good results in occupational training for the low-grade female patients. Eight nurses obtained their R.M.P.A. certificate during the year.

The *Inverness District Asylum* housed 720 patients on May 15th, 1929, while another 16 were out on probation. The recovery-rate for the year was 25·4 per cent., and the death-rate 10·7 per cent. Phthisis and senile decay accounted for more than half the deaths. On the whole the health of the patients was good, but there was an epidemic of influenza in the spring, and some cases of scarlet fever. The drought caused a very serious water shortage, but the new reservoir, completed last year, saved the situation. The medical superintendent expresses anxiety about the state of the hospital building, and thinks that the further hospitalisation of the institute requires careful consideration. A cinematograph apparatus was installed last October, and has been much appreciated. The visiting commissioner urges the provision of a workshop for occupational therapy, and of a comfortable detached home for the nurses, ten of whom gained their R.M.P.A. certificate during the year.

Lancashire and Cheshire Society for the Permanent Care of the Feeble-Minded.—The 30th annual meeting of the Society was held this year. There are now 103 women and 84 girls in the colony, and 132 men and 94 boys. One girl and two boys died during the year. There was a succession of epidemic diseases, but most of the patients made a good recovery. Sandlebridge receives patients from all over the country, and 234 of its patients have been in residence since they were small children.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 16TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 172 (the same last week); scarlet fever, 3227; diphtheria, 1759; enteric fever, 51; pneumonia, 1102; puerperal fever, 59; puerperal pyrexia, 109; cerebro-spinal fever, 10; acute poliomyelitis, 12; acute polio-encephalitis, 3; encephalitis lethargica, 17; dysentery, 15; ophthalmia neonatorum, 89. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Nov. 19th–20th was as follows:—240 under treatment, 17 under observation (last week 195 and 9 respectively), scarlet fever, 2838; diphtheria, 2080; enteric fever, 96; measles, 306; whooping-cough, 114; puerperal fever, 31 (plus 12 babies); encephalitis lethargica, 125; poliomyelitis, 8; "other diseases," 17. At St. Margaret's Hospital there were 9 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 4 (3) from enteric fever, 20 (8) from measles, 9 (1) from scarlet fever, 12 (2) from whooping-cough, 38 (5) from diphtheria, 82 (16) from diarrhœa and enteritis under two years, and 76 (12) from influenza. The figures in parentheses are those for London itself.

The single death from enteric fever outside London was reported from Birmingham. Diarrhœa accounted for 7 deaths at Manchester, 6 at Birmingham, and 4 at Liverpool. There were 5 deaths from diphtheria at Liverpool; 3 deaths from measles at Bolton and Oldham, 2 each at Wolverhampton and Manchester.

The number of *stillbirths* notified during the week was 274 (corresponding to a rate of 47 per 1000 births), including 38 in London.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

HIGHLANDS AND ISLANDS MEDICAL SERVICE.

THE House of Commons went into Committee on Nov. 19th on the following money resolution in connexion with the Highlands and Islands (Medical Service) Additional Grant Bill:—

> That, for the purposes of any Act of the present session to make provision with respect to an additional special grant for the purpose of improving medical service in the Highlands and Islands of Scotland, it is expedient to authorise the payment to the Highlands and Islands (Medical Service) Fund, in addition to the sum of £42,000 payable to the Fund under Sub-section (1) of Section (1) of the Highlands and Islands (Medical Service) Grant Act, 1913, of such sum as may be annually voted by Parliament for the purpose.

Mr. YOUNG, Chairman of Committees, was in the chair.

Mr. ADAMSON (Secretary of State for Scotland), in moving the resolution said that in 1913 Parliament made special provision for the payment of a fixed amount of £42,000 per annum for the purposes of the improvement of the medical service in the Highlands and Islands and for other purposes connected therewith. Since that date the fund had been of inestimable benefit to the people in the remote parts of Scotland. It has been found that an additional sum of money was necessary and this resolution was being proposed for that purpose.

Major ELLIOT said that the Members of the Opposition fully agreed with the object of the resolution, and in view of the lateness of the hour, and on the understanding that fuller opportunity would be afforded, if necessary, for a discussion on the matter at a later stage, they were willing to agree to the resolution. The services which the resolution covered extended to a little more than half the area of Scotland and those services had been kept up in recent years by utilising balances unexpended during the war. The time had come when a larger amount was necessary.

Mr. ERNEST BROWN signified approval of the resolution on behalf of the Liberal Party.

The resolution was agreed to.

On the following day the resolution was agreed to on Report, and the Highlands and Islands (Medical Service) Additional Grant Bill was brought in and read a first time.

ILLEGITIMATE CHILDREN (SCOTLAND) BILL.

On Wednesday, Nov. 20th, the Illegitimate Children (Scotland) Bill was read a second time.

EDUCATION (SCOTLAND) BILL.

On Tuesday, Nov. 26th, Major ELLIOT asked for leave to bring in the Education (Scotland) Bill, a measure to enable education authorities in Scotland to incur expenditure in supplying milk to children attending schools within their area. He said that the Bill followed out the rather remarkable series of tests and experiments upon the value of adding small quantities of vital substances to the ordinary diet or food, more particularly of growing animals and persons, which had been one of the features of research in the last few years. The last few years had shown most clearly that although the diet might be adequate in amount, and even contained all that was usually supposed to be necessary to produce a healthy full-grown creature, yet if certain small quantities of substances were lacking, the growing creature, be it child or animal, would not be fully formed, would not reach full maturity. All the work that had been done on what had been known as the vitamins was a striking example of that. Carrying out that line of investigation in the United States and elsewhere, experiments were made on the value of adding a small quantity of milk to the daily ration, first of all of animals, and then of growing children, and very remarkable and interesting results were obtained. These experiments were carried further in this country by the Medical Research Council, which in 1926 carried out a series of tests on boys under more or less controlled conditions, and under the management and scientific supervision of Dr. Corry Mann. Those results showed quite clearly that a remarkable increase in growth and in health, and even if he might say so in intelligence, was the result of the addition of a small quantity of milk to the daily ration of growing children.

Scientific Tests.

In the autumn of 1926 the Scottish Administration, in which he had the honour then to play a certain part, brought this to the notice of the Empire Marketing Board on the ground that they should attempt to apply these results in Scotland and elsewhere in the United Kingdom, since here was an admirable chance of encouraging the use of home products. In the case of fresh milk particularly the home producer had a natural advantage and preference over all other producers of which it is impossible really to deprive him. There was thus an excellent chance of improving health and of stimulating home production, particularly in the field of agriculture in which stimulation was highly desirable and very necessary. Accordingly a grant was made from the Empire Marketing Board and the tests were conducted over two years, in 1926 and 1927. The results were really very striking and remarkable. They thought it desirable not to publish them at once but to verify the 1926 results by the 1927 repeat tests. The tests were carried out in seven large centres—Peterhead, Aberdeen, Dundee, Edinburgh, Glasgow, Greenock, and Paisley, and also in Northern Ireland in the City of Belfast. There were some 2000 children under observation. It was under full scientific supervision, conducted in the first case by Dr. Orr, of the Rowett Institute, and Dr. Cruickshank, of the Board of Health, and in the second case by Dr. Leighton and his assistants, also of the Board of Health, now the Department of Health for Scotland. The results showed that adding a small additional ration of milk to the diet of the ordinary school child in Scotland led after a seven months' addition of this small ration to the surprising result that the ordinary child which had received milk was a quarter of an inch taller and three-quarters of a pound heavier than the child which had not received the ration. This was not due simply to a deficiency in feeding, because the children who were not receiving an additional ration of milk were given an additional ration of biscuit to make up for the food value of the milk which had been given, so that the excellent results obtained by milk were, so far as one could see, purely due to the small additional quantities of vital substances found in milk, but not found in the biscuit ration given as an alternative. It was a further interesting point that the additional biscuit ration did not lead to any increase of growth, either in height or in weight, over the children who received no additional ration at all, which seemed to point quite clearly to the fact that those children, take it by and large, were receiving sufficient food—that was to say an extra biscuit did not increase either their height or weight—but that they were receiving food which was deficient in some respects and the making up of that deficiency by a small ration of milk produced this surprising result of greater growth in height, increase in weight, and improvement in health. It was very striking that all observers said there was a sleekness of the hair, a polished condition about the nails, and there was a certain boisterousness and rebelliousness about the children on the milk diet which was not found in the cases of the children receiving the biscuit diet.

The children were of all ages from the beginning of school age to the end of it, from children of 5 and 6 up to children up to 13. The interesting thing was that this applied not merely to necessitous children, but practically to all the children, and therefore it seemed that it was scientifically proved that the diet of the ordinary child could be greatly improved by a small alteration of quality. The ordinary law just now only applied to the giving of substances in the case of children who were actually necessitous, and the full necessitous provisions had to be observed—that was to say, there was a compulsion on recovery of cost and many semi-penal provisions with which no doubt Members of the House were well acquainted. Milk obviously occupied a position something between a drug and a food, and a great many parents who came under no definition of necessity might quite reasonably find that by working in with a scheme of a local authority it would be possible either on payment of a proportion of the cost, or on payment of all the costs, or on payment of none of the costs, as the flexible nature of the scheme which he (Major Elliot) desired to introduce would permit, that their children would be greatly improved in health, although in fact they would not come under any category of necessity. The Bill would have the immediate effect of modifying the rigid provisions requiring and demanding recovery of all the costs and the supply only in cases where the parent was proved to be absolutely negligent in his care of the health of his child.

A Sound Investment.

The cost of these things tried out experimentally ran to something like 1*d.* per child per day. That was the full cost, but he would not suppose for a moment that the full cost in the case of every child would be borne by the local authority. He could not imagine any better form of investment, or anything that would be of more immediate value to a child's chances in life. Necessitated no doubt by the profession to which he and some other hon. Members belonged, he was a little sceptical about the brain, but he was perfectly solid about the brawn. If they could make a healthy child, he was certain it would pick up a great deal of its own education, whereas an unhealthy child might receive no advantage from the most careful schooling they could possibly give it. There had been other experiments of a converging kind, proving the benefit of this one. They were able to carry out a certain amount of milk feeding in Africa, where the same criticism of boisterousness and even of rebelliousness was brought against the children who had the milk ration as against those who had not. He therefore said that here they had a chance of something which could be immediately put into operation, something which would, for the expenditure of every penny of it, benefit home production, benefit agricultural production, and which would be as these tests had shown, of considerable and lasting benefit to the children of this country. In Scotland they had perhaps a more convenient area for the further examination which he proposed than in England. In Scotland agriculture, education, and public health were all under one Minister. The Bill proposed that the local authority could incur expenditure for this purpose by submitting a scheme which would have the approval of the Department of Health and of Education. It was a practical and immediate step. It was not an extravagant step, but one which they could reasonably ask the House to give a first reading to in order to get the Bill printed. He hoped thereafter at an early date they might be able to remit the Bill to the Scottish Grand Committee to amend as necessary, and that eventually it would be placed on the Statute Book.

Leave was granted to bring in the Bill, which was then read a first time.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 20TH.

Visits of Medical Experts to the Colonies.

Dr. MORGAN asked the Under Secretary for the Colonies how many medical experts, as the result of organisational departmental changes, had visited and reported on particular colonies; how many colonies had been so visited; what special health and medical problems were investigated; and if any reports based on these visits or investigations were available to Members of Parliament.—Mr. LUNN replied: I am not clear as to what organisational departmental changes are in the mind of my hon. friend, but I give the following list of visits to the colonies by medical experts which have been arranged by the Colonial Office during the last few years: Sir Wilfred Beveridge, Bahamas and other West Indian Islands; Dr. A. E. Horn, Cyprus; Dr. J. Hope Reford, Falkland Islands; Dr. A. T. Stanton (Chief Medical Adviser to the Secretary of State), Nigeria, Gold Coast, Sierra Leone, and Gambia; and Lieut.-Colonel S. P. James, Kenya, Uganda, and Tanganyika. The reports of Sir Wilfred Beveridge and Dr. Horn are available to any hon. Member who may desire to see them, and the report of Colonel James on his visit to East Africa, which was specially concerned with malarial problems, will be available shortly. In the other two cases no special report was issued. I may add that a Commission of the League of Nations recently investigated the general health problems of the Western Pacific Islands, and it is understood that their report will be published shortly.

Yellow Fever and Malaria.

Dr. MORGAN asked the Under Secretary for the Colonies whether the Rockefeller Foundation was still continuing in different colonies, in coöperation with the Colonial Medical Service, its investigations into yellow fever and also its malarial surveys; how many of the latter had been completed; and if any extension of the survey system was in contemplation.—Mr. LUNN replied: Yes, sir. I am happy to say that the International Health Division of the Rockefeller Foundation is continuing to coöperate with the local medical authorities in investigations into yellow fever in Nigeria and other West African Colonies. It is also coöperating in malarial surveys in various West Indian and Western Pacific Islands and in Palestine, and this work is still proceeding. I hope that it will be possible to extend the system of malarial surveys in coöperation with this organisation as opportunity offers.

International Commission on Sleeping Sickness.

Dr. MORGAN asked the Under Secretary for the Colonies whether the special International Commission on Sleeping Sickness was still continuing its investigations in Uganda; whether any report had been received or issued; what were the names of the present members of the Commission; and what was the total staff working under that Commission.—Mr. LUNN replied: The International Sleeping Sickness Commission appointed by the League of Nations for work in Uganda completed its labours in June, 1927, and its final report was published by the League in March, 1928. The latter part of the question does not therefore arise. I may state that an International Conference held in Paris a year ago to review the Commission's work approved the principle that the lines of investigation opened up by the Commission should be followed up by the Governments concerned with their own resources. Special organisations are now investigating problems in connexion with sleeping sickness not only in Uganda, but in the Tanganyika Territory, Nyasaland, Nigeria, and the Gold Coast.

Vitamin Contents of Cod-liver Oil.

Mr. REMER asked the Under-Secretary for the Colonies what steps he was taking to make widely known the favourable report as to the vitamin contents of cod-liver oil, as the result of investigations by the Empire Marketing Board.—Mr. LUNN replied: The Empire Marketing Board has not yet received the report upon these investigations, and I am therefore not in a position to say what steps may be found suitable for making the results known.

Dispensing in the Army.

Dr. VERNON DAVIES asked the Secretary for War if he was aware that his department was the only service department which employed men who were not trained pharmacists for the dispensing of medicines; and, seeing that such men could not be employed to dispense for the civil population under the National Health Insurance Act and were not employed by the Admiralty or Air Force, would he look into the matter.—Mr. T. SHAW replied: The hon. Member is under a misapprehension. Although some pharmacists are employed under the Admiralty on this duty, all three Service departments employ dispensers who are not pharmacists but who are trained as dispensers and carry out their duties under the general supervision of medical officers. I am advised, so far as the Army is concerned, that the present arrangements are satisfactory.

THURSDAY, NOV. 21ST.

Accused Persons Suffering from Encephalitis Lethargica.

Mr. SORENSEN asked the Home Secretary whether he intended to take action to see that accused persons known to have suffered from encephalitis lethargica received appropriate medical treatment and were not treated as criminals.—Mr. CLYNES replied: As regards accused persons sent to prison on remand or awaiting trial, if the medical officer has reason to believe that they have suffered from encephalitis lethargica a report on their medical history and present condition is made to the court, and the decision as to the action to be taken rests with the court.

Mr. OLDFIELD: Will the right hon. gentleman look into the matter of the amount of institutional treatment available for children over 14 years of age?

Mr. CLYNES: That is a very different question.

Dr. VERNON DAVIES: Are any steps taken to inquire into the previous medical history of these people or do the authorities wait for some evidence to be given to them that the case is encephalitis lethargica before making inquiries?

Mr. CLYNES: I think that my answer implies that something in the nature of a medical history is brought into the court.

Mr. SORENSEN asked the Home Secretary how many persons were convicted of moral offences during the last 12 months; and how many of that number were known to have suffered from encephalitis lethargica.—Mr. CLYNES replied: The figures available do not fit in exactly with the terms of the question, but perhaps they will serve the purpose of my hon. friend. In the two years ended March 31st, 1929, 114 prisoners were found, or suspected, to be suffering from the after-effects of this disease. As regards 16 of them, whose first conviction was before the onset of the disease, only one was in prison for a sexual offence; as regards the other 98, whose first conviction was after the onset of the disease, 22, or nearly one-quarter, were in prison for sexual offences.

Prevention of Water Famine.

Mr. REMER asked the Minister of Health what steps he proposed to take to deal with the serious shortage of water in many localities during the drought of last summer.—Mr. GREENWOOD replied: I have already issued a memorandum urging water authorities to examine their position, in view of the drought and possible difficulty in the future, and indicating the measures to be taken. In my opinion, the most practicable procedure is the formation of Advisory Regional Water Committees, who will systematically survey the needs of their districts and recommend the best and most economical means of meeting them, and I am constantly urging the formation of such committees.

Superannuation of Local Government Officers.

Mr. RAYNES asked the Minister of Health how many local authorities had adopted the Local Government and Other Officers' Superannuation Act, 1922; how many had adopted it for officers and workmen and the number of each included in designated posts; and how many officers and workmen over 65 years of age were still employed respectively by local authorities who had adopted the Local Government and Other Officers' Superannuation Act, 1922, and by local authorities who had not adopted that Act.—Mr. GREENWOOD replied: On Nov. 1st, 1929, 633 local authorities had availed themselves of the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the number of posts designated as established posts by these authorities was approximately 127,500. No exact information is available as to the numbers of officers and workmen occupying such posts, but the Departmental Committee on Superannuation estimated that on Nov. 1st, 1927, the 102,000 employees then occupying established posts included 35,000 officers and 67,000 servants. I have no information as to the number of employees of local authorities whose age exceeds 65 years.

Mr. THORNE: Has the right hon. gentleman power to compel those local authorities who are refusing to put this into operation to do so?

Mr. GREENWOOD: Under the present law I have no power to compel local authorities. That matter was raised by the Departmental Committee which reported two years ago and is now under my consideration.

Approved Societies and Additional Medical Treatment.

Mr. MANSFIELD asked the Minister of Health whether he proposed to make any alteration or amendment to the National Health Insurance Act to enable approved societies to give financial assistance towards the cost of any form of treatment, benefit, or otherwise, that a member might require, with less than five years' membership.—Mr. GREENWOOD replied: An approved society which is found on valuation to have a disposable surplus may adopt a scheme for contributing towards the cost of various forms of remedial treatment required by its members, such as dental, ophthalmic, hospital, or convalescent home treatment. Hitherto such assistance has been restricted to persons who have been members of the society for about five years, but a regulation has already been made under which the qualifying period of membership will from January next be reduced to two and a half years on the average.

Local Authorities and Rheumatic Diseases.

Dr. VERNON DAVIES asked the Minister of Health what grants, if any, were paid by his department to local authorities for the investigation or treatment of rheumatic diseases, especially among children.—Mr. GREENWOOD replied: Grants are available under the Maternity and Child Welfare Regulations for the experimental investigation and treatment of acute rheumatism in children under school age, but I am advised that this condition is rare amongst very young children. I understand that the Board of Education pay grants for similar purposes in the case of children of school age, and that the Medical Research Council make grants for researches into rheumatism.

Viscountess ASTOR: Does the right hon. gentleman not think that the best way to deal with delicate children is to establish nursery schools?

Lieut.-Colonel FREMANTLE: Have the efforts of these three departments been coördinated in any way?

Mr. GREENWOOD: They are within the knowledge of the three Ministers concerned.

Lieut.-Colonel FREMANTLE: Cannot the three Ministers coöperate?

No further answer was given.

Bacteriological Examination of Milk.

Sir RENNELL RODD asked the Minister of Health whether, in view of the large number of deaths of infants from bovine tuberculosis, traceable to milk, recorded annually in medical reports, he was satisfied that the powers of supervision and control vested in local councils were duly exercised by them; and, if not, whether he would consider measures for their stricter application.—Mr. GREENWOOD replied: I am satisfied that local authorities generally are exercising their powers of supervision and control in an efficient manner, having regard to such difficulties as are caused by the mixing of milk and the delays necessarily involved in obtaining reports on bacteriological examinations. The matter will, however, continue to receive my careful attention.

Dr. VERNON DAVIES: Is the right hon. gentleman aware that the bacteriological examination of milk for tubercle is hopelessly inadequate in this country?

No further answer was given.

River Pollution.

Mr. FREEMAN asked the Minister of Agriculture whether, in view of the growing and serious menace of river pollution all over the country and of the inadequacy of existing powers to deal with it other action was contemplated.—Mr. GREENWOOD (Minister of Health) replied: The whole question of river pollution is at present under consideration by the Joint Advisory Committee on River Pollution, and in particular they are considering measures to prevent pollution by trade effluents. They have issued a preliminary report in which they express the opinion that much more can be done, under existing powers, through the appointment of joint committees by the councils of counties and county boroughs. I am urging the authorities to set up such bodies.

Vaccine Lymph.

Mr. FREEMAN asked the Minister of Agriculture where and how Government lymph was now prepared; what animals were used in its preparation; and how many animals were so treated in 1928.—Mr. GREENWOOD (Minister of Health) replied: Government lymph is prepared at the Government Lymph Establishment at Hendon. My hon. friend will find a full statement of the technique and procedure on pages 15 to 17 of the Report of the Vaccination Committee, 1928. During 1928 438 calves and 38 rabbits were used in the preparation of the lymph.

MONDAY, NOV. 25TH.

Medical Experts and Seven-year Pension Cases.

Major COHEN asked the Minister of Pensions (1) whether he would give the House more information regarding the arrangements made for securing the assistance of independent advice in over seven years' cases from medical experts nominated by the Presidents of the Colleges of Physicians and Surgeons; whether the advice of the experts would be accepted and acted on by the Ministry; and whether all cases recommended, after investigation, by local war pension committees where he was not able to agree with the Ministry decision would be referred to the independent experts. (2) What was the method he intended to adopt in order to ensure that applicants for pensions outside the seven years' limit were given explicit opportunity to produce evidence; and (3) whether, in view of the fact that it was proposed to make use of the statutory powers of the local war pension committees to hear and investigate causes of complaint from dissatisfied applicants in connexion with the over seven years' cases, he would take steps to ensure that the fullest possible information was placed at the disposal of the war pension committees, especially where their recommendations were not accepted by headquarters, in order that the committees might be in a position to deal with and investigate cases of complaint.—Mr. F. O. ROBERTS replied: It is not in my judgment practicable or desirable at this stage to define minutely the procedure on points which experience alone can properly determine. I may say, however, that all applicants will be expressly invited by the area offices of the Ministry to state their own cases in writing and to furnish evidence in support of them. Free use will be made of the advice of the independent medical experts alluded to in all cases where there is material conflict of evidence, including cases recommended after due investigation by war pensions committees, and the fullest weight will be given to their advice, though I am naturally unable, consistently with my own responsibility in the matter, to bind myself to accept their opinion in every case. War pensions committees will, as far as possible, be made acquainted with the grounds for rejection of any case recommended by them after investigation where they may find this information necessary in order to assist them in dealing with renewed applications.

Narcotic Drugs for Medical Purposes.

Mrs. HAMILTON asked the Home Secretary the total amount of opium and other narcotic drugs required annually for medical needs in Great Britain in accordance with the formula worked out by the Health Committee of the League of Nations; the actual amount of opium derivatives and narcotic drugs of all categories manufactured in Great Britain in the latest year for which figures were available; and the actual amount of narcotic drugs of all categories exported from Great Britain in the latest year for which figures were available.—Mr. CLYNES replied: The Health Committee of the League of Nations estimated (but with some qualifications) that in countries possessing a highly developed system of medical assistance the maximum requirements of opium and its alkaloids and derivatives for medical and scientific purposes were, in terms of raw opium with 10 per cent. morphine, 4·50 milligrammes per head per year, and of cocaine 7 milligrammes per head per year. Upon the basis of this calculation and with an estimated population of 45,625,000 the maximum requirements of Great Britain and Northern Ireland were in 1928: 45,263 lb. of raw opium and 704 lb. of cocaine. The quantities manufactured in Great Britain in 1928 of the drugs to which the Dangerous Drugs Act apply were as follows:—

Medicinal opium	6,859 lb.
Morphine and its salts	9,056 ,,*
Diacetylmorphine and its salts	675 ,,
Cocaine and its salts	308 ,,

* Including 4868 lb. used in the manufacture of derivatives of opium or morphine which are not within the Dangerous Drugs Acts.

The quantities exported in 1928 were:—

Raw opium	15,956 lb.
Medicinal opium	3,394 ,,
Morphine and its salts	3,114 ,,
Diacetylmorphine and its salts	377 ,,
Cocaine and its salts	278 ,,

Figures are not available in regard to opium derivatives which are not subject to the provisions of the Dangerous Drugs Acts.

Cocaine and Cocaine Hydrochloride.

Mr. DAY asked the Home Secretary whether he had any information as to the amount of cocaine and cocaine hydrochloride that had been manufactured in Great Britain under the authority of the Home Office during the three years ended to the last convenient date.—Mr. CLYNES replied: Since the coming into force of the Dangerous Drugs Acts no cocaine was manufactured until 1928, when 1047 oz. of cocaine and 3887 oz. of the salts of cocaine were manufactured under Home Office licence.

MILLER GENERAL HOSPITAL.—This Greenwich hospital, which was founded in 1783 as a dispensary, is in danger of being compelled to close a considerable proportion of its beds. Its debt to the bankers amounts to £40,000, no more money can be borrowed, and at least £50,000 is needed to remove existing difficulties. In the last 17 years the number of beds has increased from 22 to 169, including 18 at the seaside for children. In the same period the number of out-patients has nearly doubled, and is now close upon 200,000. The hospital serves a large portion of south-east London.

DONATIONS AND BEQUESTS.—The late Sir William Towle, of the Midland Railway Company's hotels, left, among other bequests, a sum to provide an "Elizabeth Towle Bed" at the Middlesex Hospital.—The Cancer Hospital, Fulham, has received an anonymous donation of £5000.—Mr. Theodore Pim, of Snowdenham Hall, Bramley, Surrey, stockbroker, left, among other bequests, £2000 to the Royal County Hospital, Guildford; £1000 each to the London, St. Bartholomew's, and Charing Cross Hospitals; and £500 each to the Dreadnought Seamen's Hospital; Treloar's Cripples' Home, Alton; the Royal Free Hospital; the Royal London Ophthalmic Hospital; and the Meath Hospital, Dublin.—Mr. Percy Crossman, of Great Bromley Hall, Colchester, left £1000 each to the Essex County Hospital and the London Hospital.

Medical News.

UNIVERSITY OF OXFORD.—On Nov. 23rd the following degrees were conferred:—

D.M.—G. P. Wright (in absentia).
M.Ch.—C. W. Flemming.
B.M.—J. A. Eyres.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates were successful:—

Surgery.—W. J. D'Rosario, Guy's Hosp.; L. F. W. Edwards, St. Mary's Hosp.; W. J. Frith, London Hosp.; B. C. Ghose, Durham; W. A. R. Maller, St. Bart.'s Hosp.; I. W. H. Mansfield, Middlesex Hosp.; E. J. O'Loughlin, Birmingham; and S. Ramadas, St. George's Hosp.

Medicine.—R. Gilmore, Manchester; J. Gordon, St. Mary's Hosp.; M. Naylor, Sheffield; A. Schor, Basle and London Hosp.; and L. J. P. Sonomenho, Lisbon.

Forensic Medicine.—J. Britanbschki, Berlin and London Hosp.; R. F. M. Child, St. Mary's Hosp.; A. Kellner, London Hosp.; E. E. Le Feuvre, St. Mary's Hosp.; M. Naylor, Sheffield; A. Schor, Basle and London Hosp.; L. J. P. Sonomenho, Lisbon; and G. W. Sturgess, St. Bart.'s Hosp.

Midwifery.—P. S. Balachandran, Middlesex Hosp.; K. C. Bhattacharyya, St. Thomas's Hosp.; A. Buch, St. Mary's Hosp.; W. J. D'Rosario, Guy's Hosp.; L. F. W. Edwards, St. Mary's Hosp.; A. D. H. Hugo, Guy's Hosp.; T. C. Koble, St. Mary's Hosp.; W. A. R. Maller, St. Bart.'s Hosp.; C. G. Nicol, St. Mary's Hosp.; and D. Ram Annamalai, London Hosp.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: P. S. Balachandran, K. C. Bhattacharyya, R. Gilmore, and E. J. O'Loughlin.

UNIVERSITY OF DUBLIN: *Trinity College.*—At recent examinations the following candidates were successful:—

M.CH.

J. C. Fouché and H. E. Murray.

FINAL EXAMINATION FOR M.B., B.CH., AND B.A.O.

Medicine.—E. F. St. J. Lyburn, W. R. Johnston, Arnold Rose, Josephine M. Enright, Lilla M. Spiller, W. B. Hamilton, D. G. M'Caully, W. A. Y. Knight, F. O. Pilkington, A. J. Garde, G. F. West, Dora G. Bradley, R. P. M'Carrigle, Aaron Rakoff, R. E. Hemphill, F. M. Lyons, and F. S. Mackenna.

Surgery.—*G. B. Thrift, G. R. Beare, Kathleen A. Wilson, E. S. Tweedy, M. E. Kirwan, G. K. Graham, E. J. M. Bam, J. N. U. Russell, Frances E. Wilson, Dora G. Bradley, J. F. K. MacCarthy-Morrogh, and J. M. M'Elligott.

Midwifery.—*A. H. Thompson, *P. L. O'Neill, *Reginald Bowesman, J. M. Gibbon, Daniel Nolan, F. P. FitzGerald, Annie E. Thompson, T. H. Dockrell, H. H. G. Dorman, D. G. M'Caully, A. A. Lisney, J. T. Robinson, and Ruth R. Armstrong.

FINAL EXAMINATION FOR B. DENT. SC.

Dental Surgery and Pathology, &c.—D. D. Craig.

* Passed on High Marks.

UNIVERSITY OF LONDON.—At a meeting of the Senate on Nov. 20th Dr. G. A. Harrison was appointed as from Oct. 1st to the University Readership in Chemical Pathology tenable at St. Bartholomew's Hospital Medical College.

Dr. Harrison was educated at Oundle and Caius College, Cambridge, where he took a first-class in Part I. of the Natural Sciences Tripos in 1915. After clinical work at Ancoats Hospital, King's College Hospital, and elsewhere, he qualified in 1917, and went out to Mesopotamia, where he gained experience of tropical diseases. From 1919 to 1924 he was biochemist to King's College Hospital, after which he spent two years as biochemist to the Hospital for Sick Children, Great Ormond-street. Since 1926 he has been chemical pathologist to St. Bartholomew's Hospital. He was awarded the Raymond Horton-Smith prize on graduating as M.D. Camb. in 1925.

Sir Cooper Perry was appointed a member of the Board of Management of the London School of Hygiene and Tropical Medicine.

The Senate invites applications for the University chair of social biology tenable at the London School of Economics.

UNIVERSITY OF CAMBRIDGE.—The Raymond Horton-Smith prize given for the best M.D. thesis of the academic year, has been awarded to Mr. Wilfred Shaw for his thesis on Irregular Uterine Hæmorrhage. Mr. Shaw contributed a paper on this subject to the Spring number of the *Journal of Obstetrics and Gynæcology of the British Empire.*

ROYAL PHOTOGRAPHIC SOCIETY.—An exhibition of radiography will be held at 35, Russell-square, W.C., from Dec. 4th to Dec. 21st (10 A.M. to 5 P.M. daily except Sundays.) At 7 P.M. on Monday, Dec. 9th, Prof. W. L. Bragg, F.R.S., will give a popular lecture on X Ray Optics.

INSTRUCTION IN PSYCHOLOGICAL MEDICINE.—A programme of lectures and practical courses of instruction for a diploma in psychological medicine, beginning on Jan. 7th, 1930, has now been issued by the Maudsley Hospital, and may be had from the director of the Central Pathological Laboratory at the hospital, Denmark Hill, London, S.E. 5.

LONDON HOSPITAL MEDICAL COLLEGE.—The Liddle triennial prize for 1929-30, of the value of £120, will be awarded for an essay on the Cause and Incidence of Duodenal Ulcer. The prize is open to public competition, and the conditions of entry may be obtained from the Dean of the Medical College. Essays must be delivered at the hospital not later than May 31st.

OLD EPSOMIAN CLUB.—The annual general meeting of this club will be held at the Hotel Great Central, Marylebone, N.W., at 6.30 P.M. on Thursday, Dec. 12th, and will be followed by the annual dinner at 7.15 for 7.30. The chair will be taken by Brigadier-General G. T. Mair, and all Old Epsomians, whether members of the club or not, are invited to be present on this occasion. Attention is directed to the change of restaurant on this particular occasion.

YORKSHIRE ASSOCIATION OF GLASGOW UNIVERSITY GRADUATES.—The annual dinner of this Association will be held in the Great Northern Hotel, Leeds, at 7 P.M. on Friday, Dec. 6th. All graduates resident in Yorkshire or the surrounding areas are eligible for membership and are invited to the dinner. The guest of the evening will be Prof. J. Graham Kerr, F.R.S. Further information may be had from the hon. secretary, Dr. W. MacAdam, 40, Park-square, Leeds.

INFANTS' HOSPITAL, VINCENT-SQUARE.—Mr. Robert Mond, who has been a constant and generous benefactor to the hospital, has made a gift of £25,000 to the extension fund. The gift will be payable over the next seven years, and will bring up the total amount given or promised to the extension fund to well over £100,000.

ROYAL SURGICAL AID SOCIETY.—The sixty-seventh annual meeting of this Society will be held at the Mansion House, London, at 4 P.M. on Tuesday, Dec. 3rd, with the Lord Mayor in the chair.

HUNT MEET AT A HOSPITAL.—The South Oxfordshire hunt met recently at the Wingfield Orthopædic Hospital among the patients in the open air. The hounds are stated to have "enjoyed the novelty almost as much as the young patients."

ROYAL MEDICAL BENEVOLENT FUND.—A meeting of the Vice-Presidents was held at 10, Wimpole-street on Nov. 6th in response to invitations from Sir Thomas Barlow, who explained the position of the Fund, the financial details being added by Sir Charters Symonds. Various speakers in the room made suggestions for the increase of the regular income, and the general conclusion was that, while the work of the Fund is and had been of unspeakable value, and while its management was admirable, the objects for which it existed were insufficiently appreciated by the medical profession. Various steps were proposed to make the Fund better known.

QUEEN ALEXANDRA HOSPITAL, MILLBANK.—A new wing, consisting mainly of a spacious out-patient department, was opened on Nov. 26th by the Prince of Wales. The Prince was received by the Director-General, Lieut.-Gen. H. B. Fawcus. Certain members of the staff of the hospital were presented to the Prince: Bt. Col. Ryan, O.C. Hospital; Lieut.-Col. Garforth, Engineer Officer; Col. Purser, London Dir. A.D.M.S.; Maj.-Gen. Ensor, D.D.M.S. East. Cd.; Miss Osborne, Matron-in-Chief; Major Johnson, Registrar; Captain Baxter, Quartermaster; Miss Mackay, Matron; Col. Harrison, Col. Kennedy, and Col. De La Cour, Consultants. The civilian consulting staff presented included Mr. Victor Bonney, Mr. E. D. D. Davis, Sir T. Crisp English, Prof. E. H. Kettle, Sir Wm. Lister, Dr. H. MacCormac, Dr. A. G. Phear, Mr. S. Gilbert Scott, Sir John Thomson-Walker, and Mr. A. E. Webb Johnson. The Prince then proceeded to inspect the three floors of the new wing. This contains X ray rooms, departments for eye, ear, nose, and throat, dentistry work, and massage. At the top of the building, which is admirably designed, spacious, and light, is a well-arranged and equipped pathological laboratory. The Prince spent over half an hour in the building, and expressed himself as delighted with what he had seen. The commandant and officers of the R.A.M.C. Headquarter Mess received the visitors in the mess after the ceremony.

EXTENSION OF HARROW HOSPITAL.—This hospital is to be extended at a cost of £25,000. There will be accommodation for a further 30 patients and 15 nurses.

Dr. T. N. Kelynack, after nearly 28 years as physician to the Mount Vernon Hospital, has been appointed consulting physician and a member of the council of management.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Dec. 3rd.—8.30 P.M., ORTHOPÆDICS. Discussion on Minor Injuries about the Elbow-joint. Opener: Mr. W. H. Ogilvie. To be followed by Mr. Watson Jones, Mr. Jenner Verrall, and others. 8 P.M., PATHOLOGY. Meeting at the Royal Army Medical College, Millbank, S.W.

WEDNESDAY.—5 P.M., HISTORY. Sir William Hale-White: The Medical Boswells. Dr. G. C. Peachey: The Book-plates of Medical Men (with lantern slides). 8.30 P.M., SURGERY. Pathological evening.

FRIDAY.—10.30 A.M., OTOLOGY. (Cases at 9.30 A.M.) The Diagnostic Value of X Ray Examination of the Temporal Bone, and the Diagnosis of Eighth Nerve Tumours. Papers by Dr. Elsie Mann, Dr. Graham Hodgson, Mr. T. H. Just, Dr. W. T. Gardiner, Dr. T. B. Jobson, and Mr. T. B. Layton. Cases and radiograms will be shown by Mr. C. Gill-Carey, Mr. E. Watson-Williams, Dr. Imrie, and Dr. Gardiner. 5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) Cases will be shown by Mr. L. G. Brown, Dr. Dan McKenzie, Sir StClair Thomson, Sir James Dundas-Grant, Mr. V. E. Negus, Mr. H. A. Kisch, Mr. J. D. McLaggan, Mr. Archer Ryland, and others. 8.30 P.M., ANÆSTHETICS. Discussion: Anæsthesia in Rectal Surgery. Opener: Dr. J. K. Hasler.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, Dec. 2nd, to SATURDAY, Dec. 7th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., lecture by Mr. Harold Kisch: Aches and Pains in the Throat. No fee. Tues., 8.30 P.M., M.R.C.P. lecture by Dr. Kinnier Wilson: "Fits"; Varieties; Pathogenesis; Relation to Narcolepsy, Catalepsy, Syncope, &c. Fri., 8.30 P.M., at 10, Bedford-square, W.C., M.R.C.P. lecture-demonstration by Dr. Knyvett Gordon: Diagnosis of Bacterial Infection (illustrated by the epidiascope, followed by a laboratory demonstration).—HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale. Thurs., 2 P.M., demonstration by Dr. Russell Brain. No fee.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Fri., 4 P.M., lecture-demonstration by Mr. C. A. Joll: The Early and Late Results of Operations for Exophthalmic Goitre. No fee.—LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. Practitioner's Course, 4 to 5.45 P.M.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars-road, S.E., and THE INFANTS HOSPITAL, Vincent-square, S.W. Afternoon courses for two weeks. Further particulars from the Fellowship of Medicine.

UNIVERSITY OF LONDON.

THURSDAY, Dec. 5th.—5 P.M. (in the Lecture Hall of the Royal Society of Medicine), Dr. Harris P. Mosher (Harvard): The Lower End of the Œsophagus at Birth and in the Adult. (The Semon Lecture.)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

MONDAY, Dec. 2nd.—5 P.M., Mr. J. C. Dawes, M.I.Mech.E.: Disposal of Refuse.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Dec. 2nd.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations. 4.30 P.M.: Demonstration on Practical Neurology by Dr. L. R. Yealland.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Dec. 2nd.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Wards.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw, Medical Out-patients. 2.30 P.M., Sir Henry Simson: Gynæcological Operations.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. Dr. Scott Pinchin: Medical Out-patients.

THURSDAY.—11.30 A.M., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Shaw: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.

SATURDAY.—9 A.M., Mr. Vlasto: Throat, Nose and Ear Operations. 9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Children's Department.

Daily, 10 A.M. to 5 P.M., Medical, Surgical and Special Out-patients, Operations, Ward Visits, Anæsthetic Courses.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.

THURSDAY, Dec. 5th.—9 P.M., Mr. C. P. Wakeley: Diseases of the Breast and Their Treatment.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Dec. 3rd.—5 P.M., Dr. A. C. Roxburgh: Cutaneous Syphilis (1).

THURSDAY.—5 P.M., Cutaneous Syphilis (2).

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
(Intensive Week.)

MONDAY, Dec. 2nd.—2.15 P.M., Mr. Kenneth M. Walker: Urinary Calculi. 3.15 P.M., Mr. A. M. Zamora: Some Points About Mastoid Infection.

TUESDAY.—2.15 P.M., Mr. T. T. Higgins: Use of Sodium Morrhuate in the Injection Treatment of Varicose Veins. 3.15 P.M., Dr. A. Lisle Punch: Bronchiectasis.

WEDNESDAY.—2.15 P.M., Dr. Bernard E. Schlesinger: Ward Demonstration of Cases. 3.15 P.M., Dr. H. C. Semon: The Problem of the Trade Dermatoses in General Practice.

THURSDAY.—2.15 P.M., Mr. Frederick Roques: Some Modern Obstetric Methods. 3.15 P.M., Mr. E. Wolff: Headache.

FRIDAY.—2.15 P.M., Dr. Bruce Williamson: The Arrhythmias in General Practice. 3.15 P.M., Dr. C. Gouldesbrough: Osteo-arthritis.

TUESDAY.—3.15 P.M., Dr. P. O. Ellison: Investigation of Disease.

SOUTH-WEST LONDON POST-GRADUATE SOCIETY, St. James's Hospital, Ouseley-road, Balham, S.W.

TUESDAY, Dec. 3rd.—4 P.M., Mr. L. E. Phillips: Disorders of the Menopause.

CHADWICK PUBLIC LECTURES.

TUESDAY, Dec. 3rd.—8.15 P.M. (in the Inner Temple Hall, entrance from Strand and Fleet-street), Mr. W. A. Robson, Barrister-at-Law: Public Health Law and Administration.

PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, W.

FRIDAY, Dec. 6th.—6 P.M. (at the Medical Society of London, 11, Chandos-street, W.), Sir Thomas Oliver: The Mechanised Age of To-day and its Probable Effect on the Human Race.

BRITISH INSTITUTE OF RADIOLOGY.

WEDNESDAY, Dec. 4th.—2.30 P.M. (in the Central Hall, Westminster), official opening of the Exhibition and Annual Meeting by the Rt. Hon. Arthur Greenwood, the Minister of Health. 3.15 P.M., Prof. G. Forssell: Radiotherapy of Malignant Tumours in Sweden. (Mackenzie Davidson Memorial Lecture.)

THURSDAY.—6 P.M., Prof. A. S. Eddington: X Rays in the Stars. (Silvanus Thompson Memorial Lecture.)

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Dec. 4th.—4 P.M., Dr. A. C. Jordan: Dress in Relation to Health and Disease.

ANCOATS HOSPITAL, Mill-street, Manchester.

THURSDAY, Dec. 5th.—4.15 P.M., Dr. G. J. Langley: The Treatment of Empyema.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Dec. 3rd.—4.15 P.M., Dr. Crighton Bramwell: Coronary Thrombosis.

FRIDAY.—4.15 P.M., Dr. H. Dove Cormac: Some Common Forms of Mental Disorder.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

TUESDAY, Dec. 3rd.—3.45 P.M. (in the Physics Lecture Room), Dr. Maurice Davidson: Intrathoracic and Pulmonary New Growths (preceded by an exhibition of pathological specimens). (Cancer Lecture.)

FRIDAY.—3.30 P.M., Mr. Ferguson Wilson: Surgical Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, Dec. 4th.—4.15 P.M. (in the Ear, Nose and Throat Hospital). Ear, Nose and Throat Cases by the Staff.

Appointments.

ELLISON, DOROTHY, M.B., Ch.B. Edin., has been appointed Junior Resident Medical Officer, Worcester Infirmary.

ROSS, A. T., M.D., Ch.B. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Mevagissey District of Cornwall.

SHARMAN, A., M.B., Ch.B. Glasg., Surgical Research Officer, Royal Samaritan Hospital for Women, Glasgow.

SNELL, W. E., B.Sc. Lond., L.R.C.P. Lond., M.R.C.S., Tuberculosis Officer, Royal Northern Hospital Dispensary.

Stafford General Infirmary:—CAMPBELL, A. V., M.D. Liverp., D.P.H., and GILL, A. W., M.D. Edin., Hon. Visiting Physicians.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital, 91, Finchley-road, N.W.—Hon. Radiologist. Hon. Surg. Reg. Also Two H.S.'s. Each at rate of £150.

Barnstaple, North Devon Hospital.—H.S. At rate of £150.

Birmingham, Queen's Hospital.—Res. H.S. to Ophth. and Ear, Nose and Throat Dept. Res. H.S. to Cas. Dept. Each £70. Jun. R.M.O. £100. Also Res. Anæs. £70–£100.

Blackburn County Borough.—Asst. M.O.H., &c. £600.

Brighton, Royal Alexandra Hospital for Sick Children.—H.P. £100.

Bristol Royal Infirmary.—H.S. to Ear, Nose and Throat Dept.

Buxton, Devonshire Hospital.—Asst. H.P. At rate of £150.

Cairo, Egyptian University, Faculty of Medicine.—Two Surgical Tutors. £E35 monthly.

Cancer Hospital (Free), Fulham-road, S.W.—H.S. At rate of £100.

Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Hon. First Assists. for Out-patient Dept.

Charing Cross Hospital.—Surg. Reg. £150.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. At rate of £100.

Colonial Medical Service.—M.O.'S. East Africa, £600. Malaya, $500 per month.

Dewsbury and District General Infirmary.—H.S. £200.

Dreadnought Hospital, Greenwich.—H.P. and H.S. At rate of £110. Also Med. Supt. £300.

Dudley Guest Hospital and Eye Infirmary.—Asst. H.S. £150.

East Ham Memorial Hospital, Shrewsbury-road, E.—H.P. and Cas. O. At rate of £150.

Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £250.

Freemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Res. M.O. At rate of £250. Also Phys. for Electro-Therapeutic Dept.

Great Yarmouth County Borough.—Asst. M.O.H., &c. £600.

General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. At rate of £100.

Grosvenor Hospital for Women, Vincent-square, S.W.—Hon. Anæsthetist. Also Res. M.O. At rate of £100.

Hampshire County Council.—Asst. County M.O. £600.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.S. Also H.P. Each at rate of £100.

Harrogate Infirmary.—Sen. and Jun. H.S.'s. At rate of £150 and £100 respectively.

Hertford County Council.—Asst. M.O.H. for Maternity and Child Welfare Services. £600.

Hertford County Hospital.—Hon. Radiologist. Also Hon. Pathologist.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. and H.P. Each at rate of £100. Also Part-time Jun. Cas. O. At rate of £150.

Huddersfield County Borough.—Asst. M.O.H. £500.

Institute of Ray Therapy, 152, Camden-road, N.W.—Jun. M.O. At rate of £150.

Italian Hospital, Queen-square, W.C.—Two Hon. Surg.

Leeds City.—Chief Asst. M.O.H. £900.

Liverpool Hahnemann Hospital.—H.S. At rate of £100. Also Hon. Path. £25.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Asst. Med. Supt. £250.

London Hospital, E.—Cardiographic Dept.—Paterson Research Scholar. £400.

London Lock Hospital, Dean-street and Harrow-road, W.—Second Anæsthetist. 1 guinea each attendance.

London Skin Hospital, Fitzroy-square, W.—Hon. Physician and Hon. Pathologist.

London University.—Geoffrey Duveen Travelling Studentship. £450.

Manchester Ancoats Hospital.—H.S. £100. Asst. M.O. for V.D. Clinics. 1 guinea per attendance. Asst. Pathologist. Also Med. Reg. and Surg. Reg. Each £100.

Manchester, Baguley Sanatorium.—Sen. Asst. M.O. £500.

Manchester Northern Hospital for Women and Children, Cheetham Hill-road.—Sen. H.S. Also Jun. H.S. £130 and £100 respectively.

Manchester Royal Infirmary.—Res. M.O. £200. Asst. Res. Surg. O. At rate of £150. Asst. Surg. O. for Gynæcological Dept. £35. Also Asst. Surg. O. for Central Branch. £75.

Manchester, Salford Royal Hospital.—Res. Surg. O. £200. Also Two Res. H.S.'s to Special Depts. Each at rate of £125.

Metropolitan Hospital, Kingsland-road, E.—Asst. S. Also Two Anæsthetists.

Ministry of Health.—Five M.O.'s. Each £887.

Newark Hospital and Dispensary.—Res. H.S. At rate of £150.

Nuneaton Borough.—Asst. M.O.H. £600.

Plaistow Fever Hospital, E.—Jun. Asst. M.O. At rate of £300.

Poplar Hospital for Accidents, Poplar, E.—Hon. Visiting Surgeon.

Preston, Biddulph Grange Orthopædic Hospital.—Jun. H.S. At rate of £150.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Clin. Assts.

Queen Mary's Hospital for the East End, Stratford, E.—Res. M.O. £200. H.P. and Cas. O. £150. Also Three H.S.'s and One H.P. Each £120.

Radium Institute, Riding House-street, W.—H.S. £150.

St. Bartholomew's Hospital, E.C.—Physician.

St. Peter's Hospital for Stone, Henrietta-street, Covent Garden, W.C.—Clin. Assts.

Salisbury General Infirmary.—Two H.S.'s.

Sheffield Royal Infirmary.—Clin. Asst. to Medical Depts. £300.

Southport General Infirmary.—Jun. H.S. £100.

South Shields, Ingham Infirmary.—Sen. and Jun. H.S.'s £200 and £150 respectively.

Sutton, Surrey, Downs Hospital.—Jun. Asst. M.O. £500.

Tilbury Hospital, Essex.—Med. Supt. £250. Also H.S. At rate of £150.

Torquay, Torbay Hospital.—H.P. £175.

Western Australia, Lunacy Department.—Jun. Asst. Res. M.O. £450.

West London Hospital, Hammersmith-road, W.—H.P., H.S. Aural and Ophth. H.S. and Asst. Cas. O. Each at rate of £100.

Westminster Hospital, Broad Sanctuary, S.W.—Asst. Pathologist. £250.

Wigan Infirmary.—Third H.S. £150.

Willesden General Hospital N.W.—Clin. Asst. for Surgical Out-Patient Session.

Wilts County Council.—Asst. M.O.H. and Asst. School Med. Inspector. £600.

York County Hospital.—Hon. M.O. for Massage and Electro-Therapeutic Dept.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at King's Cliffe (Northants).

Births, Marriages, and Deaths.

BIRTHS.

BLACKER.—On Nov. 10th, at The Châlet, Esher, the wife of Carlos Paton Blacker, M.C., M.A., M.R.C.P., of a son.

JACKSON.—On Nov. 21st, at Mount Jocelyn, Crediton, Devon, the wife of L. N. Jackson, M.D., of a daughter.

RICHES.—On Nov. 10th, at 4, Walton House, Longford-street, Regent's Park, the wife of E. W. Riches, M.C., M.S., F.R.C.S., of a daughter.

SCOTT.—On Nov. 21st, at Stagsden, Bournemouth, the wife of Dr. Maitland Scott, of a son.

MARRIAGES.

ADAM—LLOYD.—On Nov. 10th, in London, Major Walter Eustace Adam, M.C., R.A.M.C., to Phyllis Joan, elder daughter of the late Captain Walter Lloyd, Royal Welsh Fusiliers, and of Mrs. Lloyd, Queen Anne's-mansions, St. James' Park, S.W.

BRUCE—MYERS.—On Nov. 19th, at St. John the Baptist's, Chester, George Bruce, M.A., M.B., C.M., Fairford, Cults, Aberdeen, to Frieda Elizabeth, younger daughter of the late Rev. Arthur Myers, M.A., and of Mrs. Myers, The Cottage, Melbourne, Derby.

WARD—NICHOLS.—On Nov. 14th, at Westminster Cathedral, Dr. Howard Ward, of Southampton, to Elsie, third daughter of the late Arthur and Mary Nichols, of Melbourne, Australia.

DEATHS.

GRAY.—On Nov. 19th, at "Little Haven," Ealing, of heart failure, John Alfred Gray, M.D. Lond., in his 72nd year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

NATIONAL BABY WEEK COUNCIL.

SOME CRITICAL ISSUES DISCUSSED.

AT a meeting of the Council held at Carnegie House on Nov. 20th, under the presidency of Mr. E. B. Turner, discussions on "A National Maternity Service" were based on issues arising out of the report of the Departmental Committee and the memorandum of the British Medical Association. Dr. T. Eustace Hill did not agree with the Association that the need for antenatal clinics would be reduced by the introduction of a satisfactory maternity service; if the clinics were suitably situated and equipped, and staffed by women medical officers, the demand would increase as the mothers became better informed. Miss E. M. Doubleday was of opinion that these clinics would tend to be rather in the nature of consultant centres, while Dr. J. W. Bone considered their principal function should be that of sorting patients into groups, and advising the women on such matters as general health and mothercraft. Dr. Hill and Miss Doubleday were in accord in believing that the Association's financial estimate of the scheme was far too low, and in the opinion that if a midwife was to be limited to about 100 cases a year a fee of £2 10s. a case would not provide an adequate income to attract the best type of woman. The first of the basic principles of the memorandum—"that the normal case can be safely treated at home"—was accepted by Dr. Bone and Miss Doubleday, but not by Dr. Hill, who felt there were many normal cases which required institutional treatment; he made light of the possible danger to the patients by aggregation in maternity institutions if these are "suitable so far as accommodation and staff are concerned."

Opinion was divided in regard to the proposal by the Departmental Committee to transfer the duties of inspection and the laying down of the training curriculum for midwives from the Central Midwives Board to the Ministry of Health. As a member of that committee, who had heard and read all the evidence, Dr. Hill said it had been made clear that inspection by the C.M.B. had been inadequate and perfunctory, while he himself had frequently been impressed by a tendency on the part of the Board in penal cases to show leniency which was not justified by the evidence laid before it by the local supervising authority. The C.M.B. as constituted was, he said, in no sense representative of midwives, and he was satisfied that not one per cent. of women would be deterred from entering the service because it was proposed to transfer certain minor duties to the Ministry of Health. Miss Doubleday, representing a group of midwives, agreed that the constitution of the C.M.B. needed amendment in order to make it more representative of the midwives of the country. They felt, however, that no profession could be controlled by a Government department and remain a profession, and that they ought to be governed, as the medical and nursing professions were, by an independent body. The vital point was that midwives should be supervised by people with a long practical experience of midwifery, and it was open to question whether a Government department could keep up to date in its knowledge of the professional side. The Departmental Committee's proposal amounted, it seemed, to leaving only the penal work in the hands of the Board.

THE FUTURE OF GREATER LONDON.

On Nov. 26th Mr. Arthur Greenwood, Minister of Health, accompanied by Earl Russell, Parliamentary Secretary of the Ministry of Transport, received a deputation from the Greater London Regional Planning Committee, under the chairmanship of Sir Banister Fletcher, P.R.I.B.A.

The first object of the deputation was to ask that the Government would take steps to check the evils of ribbon development on arterial roads, and it was suggested that these evils might be lessened by the following means: (1) purchase of the frontage lands by the State or the highway authority; (2) suitable agreements with the owners; (3) control of the lands adjacent to the road through town-planning schemes. A further question with which the committee had been concerned—the reservation of land for recreation grounds and other open spaces—was closely connected with that of ribbon development, since much the same difficulties arise with regard to the control over he land in question.

committee were of opinion that these difficulties t be largely solved by amendments in the Town-plan- Act, and they submitted a memorandum on the ility of reserving a green belt around London, together ome specific suggestions for the amendment of the anning Act, calculated to facilitate the reservation of land from buildings and the provision of open spaces, without imposing heavy burdens on the ratepayers. It was further suggested that additional town-planning powers should be given to county councils, which should be the authorities to acquire and hold regional open spaces, and that a body should be constituted for the Greater London area with power to prepare a master plan and scheme. This scheme should not, however, be carried beyond a provisional stage until those of the various town-planning authorities within the area were complete.

The Minister of Health said, in reply, that he was in full agreement with the general objects which the committee had set before themselves. The proposals for the reservation of open spaces and, in particular, of a green belt around London, were of great interest, though the methods to be adopted in practice would need careful examination. He was also interested in the suggestion that a special regional planning body should be constituted for the Greater London area, but he thought that local authorities would have to be consulted about this.

Lord Russell said that he fully sympathised with the views which the deputation had expressed upon the undesirability of ribbon development, from considerations both of economy and of traffic requirements. He could assure the deputation that the committee would have every support from the Minister of Transport in any practical scheme for mitigating the evil.

THE BUSCH OPTOMETER.

AT a meeting of the Optical Society, held at the Imperial College of Science and Technology, South Kensington, on Nov. 14th, Mr. A. G. Frewin, of the Emil Busch Optical Co., gave a demonstration of the Busch optometer, an instrument designed by Prof. Thorner for measuring refractive errors. By its means can be measured in diopters the hypermetropia or myopia of a symmetrical eye, or the ametropia in the two meridians of an astigmatic eye together with the directions of the meridians. The patient looks with one eye into the exit pupil of the instrument, while the observer looks into the eyepiece and focuses on the patient's macula the image of the straight filament of a small electric bulb. The focusing hand moves a scale relatively to a fixed pointer; when the side edges of the filament are sharp the ametropia may be read off at once. Freedom from glare and corneal reflections is secured by semi-circular stops which ensure that the illuminating rays are incident on the top half of the patient's cornea, whilst the light reflected from the fundus and reaching the observer issues from the lower half of the cornea. The vertex of the correcting lens is placed 12 mm. in front of the patient's cornea.

GLAXO MALTED FOOD.

IN recent articles upon the London Medical Exhibition we referred to a preparation supplied from the Glaxo Laboratories (56, Osnaburgh-street, London, N.W.) as Glaxo Malted Milk. It has been pointed out to us by the proprietors that the right name is Glaxo Malted Food, a cereal product for use as a supplementary when infants require something more than a milk diet. The preparation consists of malted barley and wheat flour, freed from bitter taste.

A HOSPITAL FORMULARY.

THE official formulary of eight Belfast hospitals has been printed and issued by the North Irish Pharmacists' Association of Belfast. It has been compiled with the consent and assistance of the medical staffs of the hospitals attached to the Belfast Medical School, and includes the prescriptions which are in common use in the out-patient departments and wards of the various hospitals. The formulary is divided into six sections beginning with general prescriptions and going on to those suitable for children, for gynæcological, throat, eye, and skin cases. Appended is a price list drawn up as a guide for hospital patients, the price of prescriptions (not including container) varying from *4d.* to a maximum of *2s. 2d.* In the addendum is a list of formulæ considered suitable alternatives to the more expensive preparations. The price of the Belfast Hospitals' Pharmacopœia is *2s.* (plus postage), and copies may be had from any of the hospitals. Many old members of the medical school may desire to possess a copy.

DIFFUSION ANÆSTHESIA OF THE PERITONEAL CAVITY.

UNDER this heading we published last week a paragraph from our Vienna correspondent describing Dr. Mandel's experiments with percain as an abdominal anæsthetic. The Clayton Aniline Company, who supply this drug, inform us that the doses mentioned were too large. The amounted inserted in the peritoneal cavity should read "350 c.cm. of a ¼ per 1000, and in later cases 250 c.cm. of a ⅛ per 1000, solution of percain."

An Address

ON

INTRATHORACIC AND PULMONARY NEW GROWTHS.

*Delivered at the University of Sheffield on Dec. 3rd, 1929,**

BY MAURICE DAVIDSON, M.D. OXF.,
F.R.C.P. LOND.,

PHYSICIAN AND DEAN OF THE MEDICAL SCHOOL, BROMPTON HOSPITAL, LONDON.

IN common with many of my colleagues I have been greatly impressed with the apparent increase during recent years in the number of cases of primary malignant disease of the lung which present themselves both in hospital and in private practice.

The appearance of cancer in the lungs in the form of secondary or metastatic deposits from tumours originating in other portions of the body is, of course, well known and calls for no special comment. The occurrence of primary growths in connexion with the lungs or bronchi has hitherto been regarded as a rarity. That the increased frequency of pulmonary carcinoma is real and not merely apparent is a fact of which I have not the slightest doubt. It has been borne in upon me by the clinical impressions of the last ten years and I know that a similar view is held by many competent observers who are in a position to form a judgment. Such a statement, however, demands at least some sort of proof, and I have, therefore, endeavoured to collect a few of the more reliable statistical observations to put forward as a basis for my contention.

A short reference to the literature of this subject may be useful, since it has now grown to such considerable dimensions. An admirable general account is given by Huguenin[1] in his recent book which includes an interesting résumé of the historical side. Of the principal authors in the last 50 years he quotes especially Fuchs and Pässler, who in 1896 collected together as many as 76 cases. In 1912, Adler[2] wrote a long treatise which has long been regarded as one of the classical sources of information. The names of Ménétrier[3] and Letulle[4] in France are specially mentioned as being always associated with the problem of pulmonary cancer. For a summary of the main pathological and statistical data reference may be made to Ewing[5] and for morbid histology to MacCallum's well-known text-book.[6] It is mainly since the war that the subject has come into great prominence, and most of the recent literature of importance is from Germany and America. Some of the most convincing evidence is summarised in Tables I. to III. and in the illustration.

TABLE I.—*Incidence of Pulmonary Cancer.*

(Figures quoted from Huguenin.)

Autopsies—number of.	Pulmonary cancer—cases of.	Author and dates.
11,400	40	Wolff.
21,000	17	Fuchs (1854 to 1896).
7,006	6	Norwiski (Lemberg) (1830 to 1903).
16,017	61	Lavrinovic (Petrograd) (1905 to 1914).

Compare with the above figures those of Berblinger (Jena) in regard to 8056 autopsies performed between 1910 and 1924. Of these 5773 were on persons over 20 years of age. Of the latter 987 had died of cancer (i.e., 17·1 per cent.). Forty-one of these cancers were primary growths of lung—i.e., 4·2 per cent. of all the cancers.

Table I. giving some of the earlier statistics and Table III. giving later figures, are quoted by Huguenin, and so striking are the details that I have thought it well worth while to reproduce them. Table II. and the figure are taken from a very instructive paper by Hanf[7] whose figures are based entirely on post-mortem records, as indeed are the Jena statistics and other recent observations. Hanf observes that an increase in lung cancer might be accounted for by fluctuations of the yearly post-mortems, or of the relative reduced post-mortems, and also by an increase in cancer generally. She seems to think that yearly fluctuations of post-mortems is an important point and remarks that very critical examination of figures is essential in this question. It appears, however, undeniable that the figures based on the percentage of total cancer cases have risen considerably and that this is definite evidence of the increase in lung cancer not only absolutely but relatively.

TABLE II.

Year.	Total autopsies.	Over age 20.	Cancer.		Cancer of the lung.						
			Total.	% of autopsies.	Total.	Male.	Female.	% of autopsies.	% of autopsies over 20 years of age.	% of cancers.	Average age.
1903	1272	914	80	6·3	3	2	1	0·2	0·3	3·7	62·3

ÆTIOLOGY AND PATHOLOGY.

There are, so far as I can determine, no facts of which we are at present aware which would indicate to us definitely any peculiar ætiology in the case of pulmonary cancer as distinct from that of cancer generally. The average age of incidence appears to be round about 50, and all statistics agree that males suffer much more than females. As regards race, Huguenin points out that the condition is less frequent in coloured races than among whites, and quotes an

NATIONAL BABY WEEK COUNCIL.

SOME CRITICAL ISSUES DISCUSSED.

AT a meeting of the Council held at Carnegie House on Nov. 20th, under the presidency of Mr. E. B. Turner, discussions on "A National Maternity Service" were based on issues arising out of the report of the Departmental Committee and the memorandum of the British Medical Association. Dr. T. Eustace Hill did not agree with the Association that the need for antenatal clinics would be reduced by the introduction of a satisfactory maternity service; if the clinics were suitably situated and equipped, and staffed by women medical officers, the demand would increase as the mothers became better informed. Miss E. M. Doubleday was of opinion that these clinics would tend to be rather in the nature of consultant centres, while Dr. J. W. Bone considered their principal function should be that of sorting patients into groups, and advising the women on such matters as general health and mothercraft. Dr. Hill and Miss Doubleday were in accord in believing that the Association's financial estimate of the scheme was far too low, and in the opinion that if a midwife was to be limited to about 100 cases a year a fee of £2 10*s.* a case would not provide an adequate income to attract the best type of woman. The first of the basic principles of the memorandum—"that the normal case can be safely treated at home"—was accepted by Dr. Bone and Miss Doubleday, but not by Dr. Hill, who felt there were many normal cases which required institutional treatment; he made light of the possible danger to the patients by aggregation in maternity institutions if these are "suitable so far as accommodation and staff are concerned."

Opinion was divided in regard to the proposal by the Departmental Committee to transfer the duties of inspection and the laying down of the training curriculum for midwives from the Central Midwives Board to the Ministry of Health. As a member of that committee, who had heard and read all the evidence, Dr. Hill said it had been made clear that inspection by the C.M.B. had been inadequate and perfunctory, while he himself had frequently been impressed by a tendency on the part of the Board in penal cases to show leniency which was not justified by the evidence laid before it by the local supervising authority. The C.M.B. as constituted was, he said, in no sense representative of midwives, and he was satisfied that not one per cent. of women would be deterred from entering the service because it was proposed to transfer certain minor duties to the Ministry of Health. Miss Doubleday, representing a group of midwives, agreed that the constitution of the C.M.B. needed amendment in order to make it more representative of the midwives of the country. They felt, however, that no profession could be controlled by a Government department and remain a profession, and that they ought to be governed, as the medical and nursing professions were, by an independent body. The vital point was that midwives should be supervised by people with a long practical experience of midwifery, and it was open to question whether a Government department could keep up to date in its knowledge of the professional side. The Departmental Committee's proposal amounted, it seemed, to leaving only the penal work in the hands of the Board.

THE FUTURE OF GREATER LONDON.

On Nov. 26th Mr. Arthur Greenwood, Minister of Health, accompanied by Earl Russell, Parliamentary Secretary of the Ministry of Transport, received a deputation from the Greater London Regional Planning Committee, under the chairmanship of Sir Banister Fletcher, P.R.I.B.A.

The first object of the deputation was to ask that the Government would take steps to check the evils of ribbon development on arterial roads, and it was suggested that these evils might be lessened by the following means: (1) purchase of the frontage lands by the State or the highway authority; (2) suitable agreements with the owners; (3) control of the lands adjacent to the road through town-planning schemes. A further question with which the committee had been concerned—the reservation of land for recreation grounds and other open spaces—was closely connected with that of ribbon development, since much the same difficulties arise with regard to the control over the land in question.

-committee were of opinion that these difficulties t be largely solved by amendments in the Town-plan- Act, and they submitted a memorandum on the ility of reserving a green belt around London, together me specific suggestions for the amendment of the 'anning Act, calculated to facilitate the reservation of land from buildings and the provision of open spaces, without imposing heavy burdens on the ratepayers. It was further suggested that additional town-planning powers should be given to county councils, which should be the authorities to acquire and hold regional open spaces, and that a body should be constituted for the Greater London area with power to prepare a master plan and scheme. This scheme should not, however, be carried beyond a provisional stage until those of the various town-planning authorities within the area were complete.

The Minister of Health said, in reply, that he was in full agreement with the general objects which the committee had set before themselves. The proposals for the reservation of open spaces and, in particular, of a green belt around London, were of great interest, though the methods to be adopted in practice would need careful examination. He was also interested in the suggestion that a special regional planning body should be constituted for the Greater London area, but he thought that local authorities would have to be consulted about this.

Lord Russell said that he fully sympathised with the views which the deputation had expressed upon the undesirability of ribbon development, from considerations both of economy and of traffic requirements. He could assure the deputation that the committee would have every support from the Minister of Transport in any practical scheme for mitigating the evil.

THE BUSCH OPTOMETER.

AT a meeting of the Optical Society, held at the Imperial College of Science and Technology, South Kensington, on Nov. 14th, Mr. A. G. Frewin, of the Emil Busch Optical Co., gave a demonstration of the Busch optometer, an instrument designed by Prof. Thorner for measuring refractive errors. By its means can be measured in diopters the hypermetropia or myopia of a symmetrical eye, or the ametropia in the two meridians of an astigmatic eye together with the directions of the meridians. The patient looks with one eye into the exit pupil of the instrument, while the observer looks into the eyepiece and focuses on the patient's macula the image of the straight filament of a small electric bulb. The focusing hand moves a scale relatively to a fixed pointer; when the side edges of the filament are sharp the ametropia may be read off at once. Freedom from glare and corneal reflections is secured by semi-circular stops which ensure that the illuminating rays are incident on the top half of the patient's cornea, whilst the light reflected from the fundus and reaching the observer issues from the lower half of the cornea. The vertex of the correcting lens is placed 12 mm. in front of the patient's cornea.

GLAXO MALTED FOOD.

IN recent articles upon the London Medical Exhibition we referred to a preparation supplied from the Glaxo Laboratories (56, Osnaburgh-street, London, N.W.) as Glaxo Malted Milk. It has been pointed out to us by the proprietors that the right name is Glaxo Malted Food, a cereal product for use as a supplementary when infants require something more than a milk diet. The preparation consists of malted barley and wheat flour, freed from bitter taste.

A HOSPITAL FORMULARY.

THE official formulary of eight Belfast hospitals has been printed and issued by the North Irish Pharmacists' Association of Belfast. It has been compiled with the consent and assistance of the medical staffs of the hospitals attached to the Belfast Medical School, and includes the prescriptions which are in common use in the out-patient departments and wards of the various hospitals. The formulary is divided into six sections beginning with general prescriptions and going on to those suitable for children, for gynæcological, throat, eye, and skin cases. Appended is a price list drawn up as a guide for hospital patients, the price of prescriptions (not including container) varying from 4*d.* to a maximum of 2*s.* 2*d.* In the addendum is a list of formulæ considered suitable alternatives to the more expensive preparations. The price of the Belfast Hospitals' Pharmacopœia is 2*s.* (plus postage), and copies may be had from any of the hospitals. Many old members of the medical school may desire to possess a copy.

DIFFUSION ANÆSTHESIA OF THE PERITONEAL CAVITY.

UNDER this heading we published last week a paragraph from our Vienna correspondent describing Dr. Mandel's experiments with percain as an abdominal anæsthetic. *The Clayton Aniline Company*, who supply this drug, inform us that the doses mentioned were too large. The amounted inserted in the peritoneal cavity should read "350 c.cm. of a ¼ per 1000, and in later cases 250 c.cm. of a ½ per 1000, solution of percain."

evidences of pressure is more likely to be met with in growths of the mediastinum than in bronchial or pulmonary lesions. *General weakness* is usually complained of, but loss of weight, though of great importance in differential diagnosis, is by no means a constant symptom, and the general nutrition and healthy appearance of some patients who are known to have an intrathoracic growth is occasionally a remarkable feature. A point in the history which is worth noting is the frequency with which the patient will mention an attack of so-called influenza, from which he will often date the onset of his more obvious feeling of ill-health. I have mentioned the word influenza because this is the expression most commonly used by patients themselves, but occasionally there will be a *history of pneumonia or possibly bronchitis*. The explanation, I believe, is that in the very early stages pulmonary cancer is, like many other cancers, symptomless; at a certain period in the development of the disease the involvement of lung tissue results in a definite reaction of some sort within the body—in many cases owing to secondary infection—and this is interpreted in terms of its more superficial manifestations, the true underlying cause being unrecognised. I think that it is at this stage that the cardiac displacement seen so often in the radiographic appearances takes place; but this is a point of conjecture and one which it is difficult to establish.

Physical Signs.

The physical signs in the chest of necessity vary considerably according to the size and situation of the lesion, the same being true of the appearances seen in a radiogram. Growths in the mediastinum, like some aneurysms, may give rise to no appreciable signs on examination and may show an equally negative picture with X rays and diagnosis may not be possible until a later stage, when involvement of the recurrent laryngeal nerve may give rise to a typical abductor paralysis of one vocal cord, or pressure on other structures cause symptoms which reveal the real nature of the trouble. Where the growth bears a closer relation to the surface of the body, dullness to percussion is the most common sign, the degree of dullness depending on the size of the growth and the extent of lung and pleural involvement. In the case of a growth which has not spread far beyond the bronchus, quite definite dullness to percussion as well as opacity of the corresponding area in the skiagram may appear, owing to the relative atelectasis of that area of lung supplied by the obstructed division of the bronchus in question. I shall refer in a moment to some of the details of radiological examination, but it is convenient at this point to call attention to the early effects of bronchial obstruction upon both the clinical and radiological signs. Golden,[9] of New York, has shown in a series of radiological studies the development of bronchial carcinoma in two stages, a stage of invasion and a stage of bronchostenosis, the latter being characterised by bronchiectasis, infection, atelectasis, and pleural thickening, with or without fluid. According to his observations it seems that these changes probably occur in the order *in which they have just been mentioned, and this is*, I think, very much in accord with our own experience in this country.

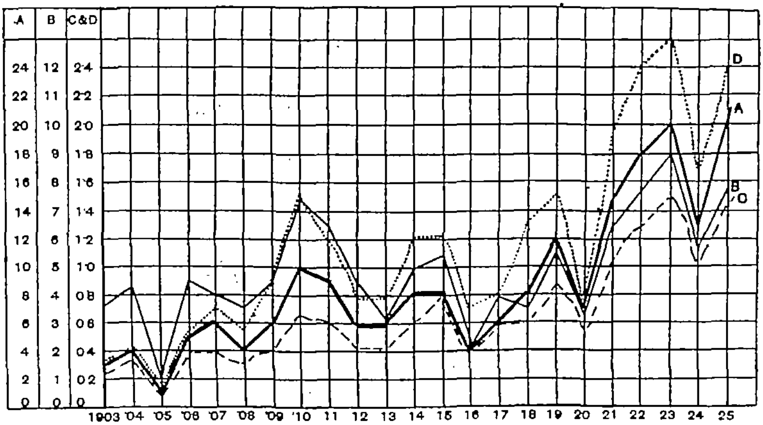

Chart showing incidence of pulmonary cancer at the Charité Hospital, Berlin, from 1903 to 1925. (D. Hanf: Virchows Archiv. f. Path.-Anat., 1927, cclxiv., 307.) A—Absolute figures for cancer of the lung. B—Percentage based on total cancer. C—Percentage based on post-mortem examinations on persons of all ages. D—Percentage based on post-mortem examinations on persons over 20 years of age.

Radiological Examination.

I now come to the radiological aspect of this matter, and although I do not want to say anything which might seem to lessen one's conception of the primary importance of accurate case-taking and methodical physical examination, I must emphasise the paramount importance of radiology in the differential diagnosis of such lesions as we are now considering. I have already indicated the variation which one may expect to find both in the symptomatology and in the physical signs, and the same is true of appearances presented to the radiologist. This once again emphasises the necessity of adequate coöperation between radiologist and clinician in the study of disease of the chest. Often radiographic examination alone is insufficient, and one has recourse both to the intratracheal injection of lipiodol and the introduction of air or oxygen into the pleural cavity as aids to radiological diagnosis.

I need not spend time in the discussion of the technical details of artificial pneumothorax induction of which a full description may be found in the late Dr. Rivière's admirable book.[10] The technique of lipiodol injection is simple enough, the main difficulty being due to the extreme viscidity of the oil. Burrell[11] uses a syringe with a screw piston and injects the lipiodol through the cricothyroid membrane. I myself have used the ordinary type of serum syringe and prefer injecting just below [illegible] into the

evidences of pressure is more likely to be met with in growths of the mediastinum than in bronchial or pulmonary lesions. *General weakness* is usually complained of, but loss of weight, though of great importance in differential diagnosis, is by no means a constant symptom, and the general nutrition and healthy appearance of some patients who are known to have an intrathoracic growth is occasionally a remarkable feature. A point in the history which is worth noting is the frequency with which the patient will mention an attack of so-called influenza, from which he will often date the onset of his more obvious feeling of ill-health. I have mentioned the word influenza because this is the expression most commonly used by patients themselves, but occasionally there will be a history of pneumonia or possibly bronchitis. The explanation, I believe, is that in the very early stages pulmonary cancer is, like many other cancers, symptomless; at a certain period in the development of the disease the involvement of lung tissue results in a definite reaction of some sort within the body—in many cases owing to secondary infection—and this is interpreted in terms of its more superficial manifestations, the true underlying cause being unrecognised. I think that it is at this stage that the cardiac displacement seen so often in the radiographic appearances takes place; but this is a point of conjecture and one which it is difficult to establish.

Golden,[9] of New York, has shown in a series of radiological studies the development of bronchial carcinoma in two stages, a stage of invasion and a stage of bronchostenosis, the latter being characterised by bronchiectasis, infection, atelectasis, and pleural thickening, with or without fluid. According to his observations it seems that these changes probably occur in the order in which they have just been mentioned, and this is, I think, very much in accord with our own experience in this country.

RADIOLOGICAL EXAMINATION.

I now come to the radiological aspect of this matter, and although I do not want to say anything which might seem to lessen one's conception of the primary importance of accurate case-taking and methodical physical examination, I must emphasise the paramount importance of radiology in the differential diagnosis of such lesions as we are now considering. I have already indicated the variation which [illegible] expect to find both in the symptomatology [illegible] in the physical signs, and the same is true of [illegible] appearances presented to the radiologist. This [illegible] again emphasises the necessity of adequate co-operation between radiologist and clinician in the study of disease of the chest. Often radiological examination alone is insufficient, and one [illegible] often [illegible] both to the intratracheal injection of lip[illegible] [illegible] the introduction of air or oxygen into the [illegible] cavity as aids to radiological diagnosis.

I need not spend ti[illegible] the discussion of the technical details of artificial pneumothorax induction of which a full description may be found in the late Dr. Riviere's admirable book.[10] The technique of lipiodol injection is simple enough, the main difficulty being due to the extreme viscidity of the oil. Burrell[11] uses a syringe with a screw piston and injects the lipiodol through the cricothyroid membrane. I myself have used the ordinary type of serum syringe and prefer injecting just below the cricoid into the upper portion of the trachea. The introduction of the oil by means of a laryngeal syringe through the glottis may often be carried out satisfactorily, but it has the disadvantage of uncertainty, in that some patients cannot tolerate the procedure. Lipiodol injection will often give invaluable assistance not only in the diagnosis of growth in the chest but in the more accurate determination of the extent and position of the growth itself.

BRONCHOSCOPY, THORACOSCOPY, AND EXPLORATORY THORACOTOMY.

Of bronchoscopy I would say that it is a means of examination, the possibilities and value of which have not received in this country the recognition which they deserve. It is true that the results of bronchoscopic examination may be entirely negative, but used in conjunction with other methods it should not be neglected, especially in those cases in which clinical and radiological examination have failed to establish a diagnosis and where definite evidence of stenosis of the bronchus may be furnished by direct vision through the bronchoscope.

Thoracoscopy may be of the greatest value. Some of the illustrations which I have exhibited here were made during the examination of one of my own cases at Brompton by Mr. Tudor Edwards[12] in which the cauterisation of adhesions was considered necessary. In cases of new growth the results of endoscopic examination may often furnish no information of diagnostic value; on the other hand, they may be of the greatest assistance. Like other methods of examination thoracoscopy must not be regarded alone, but in conjunction with other sources of evidence.

The final diagnosis of an intrathoracic lesion may, as in abdominal conditions, only be determined by an exploratory operation, although invaluable help may have been afforded to the surgeon by the previous examination if this has been carefully carried out. History repeats itself, and between the surgery of the abdomen and the surgery of the chest it is possible to make an interesting comparison. While at the present time one is bound to admit that the possibilities in regard to the treatment of intrathoracic neoplasms have considerable limitations, the successes of modern surgery in the removal of some of the less malignant forms have justified an attitude of determined expectancy. The use of radium in the treatment of pulmonary or mediastinal tumours, either alone or in combination with surgical measures, is to be encouraged, since no one can yet say the last word as to its possibilities or its limitations. I would deprecate very strongly the tendency to premature statements in respect of radium therapy, for I can conceive of no greater disservice to the public on the part of the medical profession than the broadcasting of optimistic encouragement which is not fully justified by scientific facts. The therapeutic aspect of intrathoracic and pulmonary new growths has indeed many disappointments, but I feel it no exaggeration to say that the advances of the last ten years have led those of us [illegible] are concerned with this work to regard it [illegible] increase of confidence and with a vast [illegible]sonable hope.

AN ELECTROCARDIOGRAPHIC STUDY OF THE HUMAN HEART DURING AND AFTER NITROUS OXIDE ANÆSTHESIA.

BY G. E. S. WARD, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL;
AND
SAMSON WRIGHT, M.D., M.R.C.P. LOND.,
LECTURER IN PHYSIOLOGY, UNIVERSITY OF LONDON, KING'S COLLEGE.

From the Electrocardiographic and Physiological Department, Middlesex Hospital.

THE changes which take place in the human heart during and after nitrous oxide anæsthesia have been studied by means of the electrocardiograph. All the observations were made on healthy young students who volunteered for the purpose. The patient was placed in the recumbent position and control electrocardiographic curves were first taken from all three leads. Anæsthesia was then induced with nitrous oxide, and curves from lead II. only were taken at short intervals during the induction period and for several minutes afterwards. In most of the experiments pure nitrous oxide was given in the usual dental fashion, using a well-fitting face-piece connected to a gas-bag and cylinder. In some cases, however, air was given deliberately or inhaled accidentally during the induction. Deep anæsthesia was always obtained, and the gas was discontinued as a rule just before the onset of jactitation; in some instances slight or severe convulsions took place. Considerable cyanosis usually developed. The duration of the induction period varied from 47 seconds to 90 seconds, the average time being about 1 minute in the 16 subjects studied. In addition, a small number of observations have been made under gas and oxygen.

The results with pure nitrous oxide were as follows.

Stage of Induction.

1. *Rate of Heart.*—There is an acceleration at the commencement of the induction which is emotional in origin. A further increase in rate occurs as consciousness is lost, and the maximum heart-rate is observed when the anæsthesia is at its deepest. The final rates varied from 106 to 145 per minute.

2. *Auricular Complex.*—The behaviour of the P wave showed considerable variation in the different individuals. In most cases it was not appreciably affected. In a few subjects it increased markedly in height, the largest rise being from an initial value of 3·5 mm. to 9·5 mm. (Fig. 5). In one subject the P wave decreased from 5 to 3·5 mm. during the induction, while in another subject (who had shown at first augmentation of the wave) the P wave disappeared completely at the depth of the anæsthesia.

3. *P–R Interval.*—The P–R interval was surprisingly stable in our experiments. In only one case was it prolonged, and then did not exceed 0·2 seconds. In a few subjects there was slight shortening of the interval; this was most obvious in the subject with the longest initial interval.

4. *Ventricular Complex.*—The most striking and constant changes were noted in the T wave which was affected in all subjects. In every case a decrease in height was observed. In seven cases it was abolished completely or reduced to negligible dimensions (Fig. 1); in one subject the T wave was completely inverted (Fig. 2). In several instances the S wave was followed by a long iso-electric period which ended in a small positive deflection (Fig. 5).

The R wave was decreased in almost every case. The reduction in the size of R did not necessarily run parallel with the changes in T. Thus in Fig. 2 the T wave was abolished after 20 seconds' inhalation of nitrous oxide, but the R wave was only reduced from 29·5 to 27 mm. The largest reductions were of the order of 25 per cent.—e.g., from 21 to 16 mm., 25 to 20 mm., or 18 to 14 mm. In one instance an increase in the wave was obtained. Out of six subjects with a well-marked S wave, a reduction was noted in five—e.g., from 7 to 5·5 mm., or 5·5 to 4·5 mm.

Recovery Period.

Soon after the nitrous oxide is discontinued recovery sets in,

1. Reduction in the rate of the heart takes place very rapidly, as is clear from the subjoined table.

Subject.	Rate at end of anæsthesia.	Interval.	Rate at end of interval.
1	131	18 sec.	92
2	142	27 "	109
3	118	47 "	97
4	130	25 "	86
5	133	1 min.	80

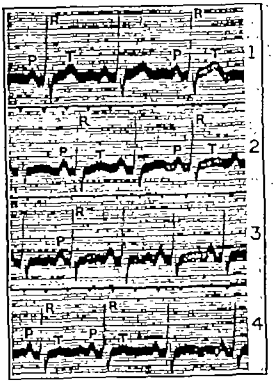
After three or four minutes the rate is usually less than it was before the administration was commenced.

2. After air was given, the P wave underwent reduction in five subjects to less than its height in the control curves.

3. The P–R interval if it had been previously modified soon became normal. (Fig. 1, curve 4, however, shows slight shortening of the P–R interval after administration of air.)

4. In three subjects the R wave was further definitely decreased. Thus in subject Ro. the initial height of the wave was 21·5 mm., at the depth of anæsthesia 17·5 mm., and after breathing air for 25 seconds it was 14·5 mm. In nine subjects the R wave had not completely recovered at periods of four to eight minutes after the anæsthetic was discontinued—e.g., initial height 28 mm., at depth of anæsthesia 18 mm., 6 minutes 25 seconds later 23 mm. In two cases the R wave finally definitely exceeded its level in the control curves (Fig. 2, curve 5).

FIG. 1.



Subject B. In this and the other figures all records are from lead II; the time is shown in 1/5th secs. and the height of waves in curves in mm. (1 millivolt = 1 cm. on original records). Pure N_2O inhaled for 47 secs. During administration, heart-rate increased from 94 to 133 per min. T wave abolished after 37 secs.; R wave decreased. After administration heart-rate rapidly returned to below its original level. Recovery in T wave noticeable after breathing air for 15 secs. But after 2 min. (not illustrated), neither T nor R has fully recovered.

Curve 1 is a control curve taken before anæsthesia. Rate 94 per min. P 5+. R 25. T 6+. S 7. Induction with pure nitrous oxide commenced at 0 min. 0 sec.

Curve 2.—After 20 secs. Rate 120 per min. P 5+, 6. R 19, 20. S 4, 6. T almost abolished.

Curve 3.—After 37 secs. Rate 133 per min. P 5, 5+. R 19, 22. S 4, 6 (8). T abolished. Anæsthetic discontinued at 47 secs.

Curve 4.—After 1 min. 2 secs. (after 15 secs. air). Rate 104 per min. P 5, 5+. R 18, 20. S 5, 6. T just returning. P–R interval *decreased* slightly.

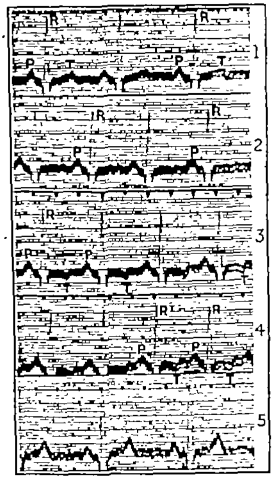
5. The T wave invariably began to return as soon as air was given. The recovery may be obvious after 15 seconds or less. Complete recovery took place in all but two subjects, the shortest time taken being 67 seconds. In two cases the T wave finally exceeded its height in the control curves (Fig. 2, curve 5).

Discussion.

These results show that striking functional changes take place in the heart during the inhalation of pure nitrous oxide. There is marked tachycardia; the auricle shows variable changes, but conduction in the bundle of His is but little altered. When pure nitrous oxide is breathed, oxygen is washed out from the alveolar air and from the blood, so that an extremely severe anoxæmia is acutely produced, as is indicated by the development of cyanosis. Some decrease in the alveolar and arterial CO_2 probably takes place too, owing to the hyperpnœa which often occurs. The changes in the heart illustrated in the electrocardiographic curves might be due to the direct action of the nitrous oxide or they might be secondary to the accompanying anoxæmia.

This problem can be decided to a considerable extent by comparing the electrocardiographic changes under pure gas with those under gas combined with sufficient oxygen to prevent anoxæmia. Fig. 3 shows that in the subject Ro. after 25 seconds' inhalation of pure gas, the T wave was abolished, the R wave reduced from 21·5 to 16·5 mm., and the rate increased from 90 to 124 per minute. At 53

FIG. 2.



Subject G. Pure N_2O administered for 90 secs. During the administration the heart-rate increased from 90 to 124 per min. After 20 secs. the T wave was abolished. After 45 secs. T was definitely inverted; P–R interval was unchanged. Following administration the rate decreased to 77 per min. The T wave became upright again. Finally both R and T exceeded their amplitude in the control curve. The string was carefully restandardised before curve 5 was taken.

Curve 1.—Control curve taken before anæsthetic. Rate 90 per min. P 5½. R 20, 30. T 4, 5. S 2, 3. Induction with pure nitrous oxide commenced at 0 min. 0 sec.

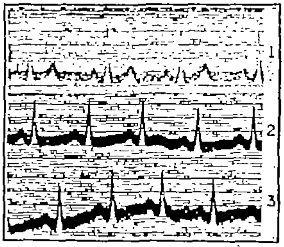
Curve 2.—After 20 secs. Rate 108 per min. P 5½, 6. R 20, 28. S 2, 3. T abolished; long iso-electric period after S terminating in deflection which is first diphasic and then negative.

Curve 3.—After 45 secs. Rate 110 per min. P 5½, 6. R 27, 29. S 3, 4. T inverted. P–R interval unaltered.

Curve 4. After 1 min. 30 secs. Anæsthetic discontinued. Rate 124 per min. P 5, 6. R 28. T inverted. P–R interval unaltered.

Curve 5.—After 6 min. 40 secs. Rate 77 per min. P 5½, R over 30. T 7, 8.

FIG. 3.



Subject Ro. Pure N_2O inhaled for 53 secs. During administration the heart-rate increased from 90 to 130 per min. The T wave was abolished after 25 secs. The R wave decreased from an average value of 21·5 mm. to 17·5 mm. After administration further reduction in the height of the R wave to 14·5 mm. occurred. After 25 secs. breathing air the rate had fallen to 85 per min. and considerable recovery of T had taken place. In this subject after 4 min. 15 secs. R and T had not fully recovered.

Curve 1.—Control curve before anæsthetic. Rate 90 per min. P 5. R 21, 22. T 6½, 7. Induction with pure nitrous oxide begun at 0 min. 0 sec.

Curve 2.—After 25 secs. Rate 124 per min P 5, 6. R 16, 17. T trace or abolished.

Curve 3.—After 53 secs. Anæsthetic discontinued. Rate 130 per min. P 6. R 17, 18. T absent at first, then recovery commenced.

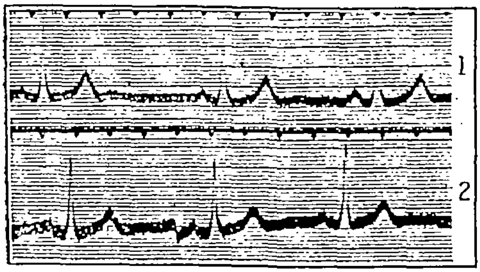
seconds the anæsthetic was removed; the pulse-rate was 130, the T wave was absent at first and then showed commencing recovery, and the R waves averaged 17·5 mm. At 68 seconds (25 seconds later) the T wave had recovered to 5 mm., though further decrease in the R (to 14·5 mm.) had occurred. Fig. 4 shows the effects of gas combined with adequate amounts of oxygen. After 4 minutes 15 seconds anæsthesia was present and the conjunctival reflex was lost; the pulse-rate, however, was only 73 per minute and the ventricular complex was not markedly different from that noted in the control curves.

Schneider and Truesdell[1] produced acute anoxæmia in normal subjects by inhalation of nitrogen for periods of 47 to 112 seconds (average 82 seconds). None of their subjects completely lost consciousness, though in some cases twitching was noted. The pulse-rate was found to increase from an initial level of 95 per minute to a final value of 120 per minute. When air was again breathed the pulse-rate returned to normal or below normal in 40 seconds. It seems justifiable to conclude that the tachycardia observed under pure nitrous oxide anæsthesia is wholly due to the accompanying anoxæmia.

Greene and Gilbert[2] observed changes in the T wave (similar to those noted by us) in chronic anoxæmia in man. In their experiments the oxygen-content of the inspired air was gradually lowered so that after 20 to 30 minutes a final value of 5 to 10 per cent. was reached.

Some reduction in the height of the T wave may occur during simple emotional tachycardia. In our experience the extent of such reduction for an increase in heart-rate of about 30 per minute is of the order of 1 to 3 mm. only.* The marked reduction, abolition or inversion of the T wave which we have described must be mainly due to the anoxæmia affecting the heart otherwise than through simple acceleration. This view is confirmed by the record shown in Fig. 5, which shows the effect of accidental inhalation of a breath of air during the induction period. The heart-rate is 124 per minute in Fig. 5 (curve 2), compared with 120 per minute in Fig. 5 (curve 3) after the air was breathed. Although the tachycardia persisted, immediate partial recovery of the T wave is noted in Fig. 5 (curve 3) which is presumably due to the beneficial effects of the oxygen breathed.

FIG. 4.

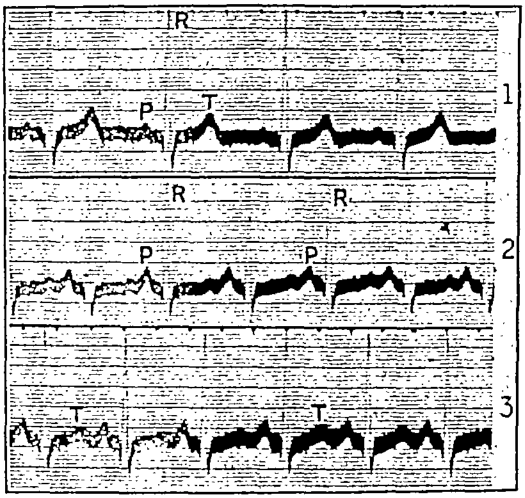


Same subject as Fig. 3. on another occasion. Curve 1 is a control curve taken before anæsthetic. Rate 57 per min. P 4, 5. R 20, 21. T 7½, 8. Gas and oxygen were given for 4 mins. 15 secs., in the proportions of about four parts N_2O to one part O_2 approximately: the conjunctival reflex was absent. At this point curve 2 was taken. Note that the heart-rate was only 72 per min. and that little decrease in the height of R or T had occurred. (P 4, 4½. R 20, 22. T 6, 7.) Compare with Fig. 3.

The cause of the changes in the R wave is not so clear. Marked decrease in the R wave usually occurs during pure nitrous oxide anæsthesia, and is absent with gas and oxygen. It must be pointed out, however, that further decrease in the height of the R wave may take place after air is administered.

Lewis and Mathison[3] observed heart-block from acute anoxæmia in the cat. In their experiments the heart-block developed after a latent period of 1½ to 4½ minutes. The absence of heart-block in our experiments may have been due to the shorter duration of the anoxæmia.

FIG. 5.



Subject S. 1 is control curve taken before anæsthetic. Rate 82 per min. P 3, 4. R 34, 35. S 5, 6. T 7. Pure N_2O was then inhaled for 55 secs. After 20 secs. (curve 2) the heart-rate increased to 124 per min. The P was 6·5 mm. compared with 3·5 mm. originally. T was abolished and replaced by a small positive deflection at the end of a long iso-electric period which followed S. At 37 secs. a breath of air was inhaled (curve 3). The heart-rate was scarcely altered (120 per min.) but considerable recovery in T immediately took place. (T variable in height up to 5.) P still exaggerated, 6½, 7.

Conclusion.

There is still considerable difference of opinion about the significance of the normal T wave of the electrocardiogram (for discussion see Katz[4]). It is widely held that the T wave represents the "stage of retreat"—i.e., the disappearance of the excitation process at the apex and its persistence at the base of the heart. There is a general consensus of opinion that abolition or inversion of T in lead II. indicates serious functional or structural cardiac derangement. It seems justifiable to conclude that the acute anoxæmia produced during anæsthesia with pure nitrous oxide seriously depresses the ventricular myocardium. The change is of a temporary nature, and is rapidly recovered from; but even in our healthy subjects recovery was sometimes not complete after several minutes. It is possible that in patients with heart disease the immediate changes might be of a more serious nature, and it is conceivable, too, that they might be of a more lasting character. It suggests that pains should be taken in such patients to avoid any anoxæmia developing by giving adequate amounts of air or oxygen in combination with nitrous oxide.

Summary.

The changes in the human heart during pure nitrous oxide anæsthesia have been studied electrocardiographically in 16 subjects. The principal results obtained were (1) tachycardia; (2) reduction, abolition, or inversion of the T wave in lead II.; (3) reduction in the R wave; (4) variable changes in the P wave; (5) little change in the P–R interval. The tachycardia and modifications in the T wave are attributed to the accompanying anoxæmia. The practical implications of these findings are discussed.

We are indebted to Drs. Anderson, Gray, Rose, and Slaughter for help with the administration of the

---

* Compare, for example, the height of the T waves in the control curves of Figs. 3 and 4, in which the pulse-rates in one subject were 90 and 57 per minute respectively.

anæsthetics, and to the students of the hospital who kindly offered themselves as subjects for this work.

ASTHMA IN CHILDREN.

THE VALUE OF SUGAR IN ITS PREVENTION AND TREATMENT.

WITH A NOTE ON THE TREATMENT OF INFANTILE ECZEMA.

BY A. ARNOLD OSMAN, D.S.C., M.R.C.P.LOND.,

PHYSICIAN, QUEEN MARY'S HOSPITAL, STRATFORD, E.; MEDICAL ASSISTANT, GUY'S HOSPITAL.

(From the Department for Medical Investigations, Queen Mary's Hospital).

IN a previous paper[1] attention was drawn to the importance of ensuring an adequate supply of sugar, in any form, in the diet of children, and it was shown how readily many of the minor symptoms of disordered health in children can be cured and prevented by this simple measure. It was pointed out, too, that amongst the disorders which apparently yielded quite readily to this treatment were some cases of asthma. The object of the present paper is to record four cases of typical bronchial asthma in children who have been rendered entirely free from attacks over periods of one to two and a half years by the simple addition of sugar to the diet and without any other form of treatment. During the past six years other cases have been treated in the same manner, with success varying chiefly with the care and persistency with which the treatment has been supervised by the parents, though it is not to be expected that all cases will respond so favourably as the four described below.

Rackemann[2] has shown that asthma in children is often completely controlled by careful attention to the hygienic conditions under which the child lives, but in the cases considered here an increased allowance of sugar in the diet was the only alteration made in the daily life of the child. All the patients were treated at home by the parents, and were seen regularly in the out-patients' department at fortnightly intervals. The treatment simply consisted in giving three drachms of powdered glucose in lemonade three times a day, in between meals, with extra sugar and "sweets" as recommended in the paper referred to above[1] for debilitated children. In each case this treatment resulted in a marked improvement in the general health and spirits, in addition to the complete disappearance of the asthma. No evidence has been obtained as to the mode of action of sugar in these cases, but I am inclined to attribute its beneficial effects to the improvement in the general health. Barber and Oriel,[3] however, consider that in these cases there is some hepatic dysfunction, and that sugar exerts its beneficial action on the liver.

CASE 1.—A boy, aged 8 years, had suffered from bronchial asthma since he was 3 years of age. Up till then he had been in normal health. The attacks apparently dated from whooping-cough contracted at the age of 3. The attacks generally occurred at monthly intervals throughout the year, and lasted for two or three days. He was an only child, small, pale, thin, and delicate-looking, but bright and intelligent, sometimes, but not habitually, constipated. His tonsils and adenoids had been removed at 4½ years of age. There was no family history of asthma or eczema. At the age of 6 he began to have typical attacks of cyclical vomiting with the usual pyrexia. These attacks occurred at about monthly intervals but did not coincide with the attacks of asthma or bear any apparent relation to the latter, though on two occasions the history of the symptoms suggests that the asthma was preceded by symptoms of cyclical vomiting—viz., pyrexia, headache, and vomiting.

Treatment was commenced in August, 1926, and he was given three drachms of glucose thrice daily, with extra sugar at meals, and sweets. Until December, 1928, he had no further attacks of asthma. For the previous 12 months he had ceased to attend hospital, and he admitted that he had recently not been having his usual allowance of sugar; as a result, he had a single attack of asthma. The treatment was resumed and since then, until he was last seen in August, 1929, he had had no more asthma or cyclical vomiting. This boy has therefore had only one attack of asthma during the past three years.

CASE 2.—A boy of 8, the elder of two children, was thin, small for his age (weighing 40 lb. 4 oz.), and very nervous. He looked a good colour and was not constipated. The family history as regards asthma was unreliable. He had never suffered from cyclical vomiting. At the age of four months he had had "eczema," and at two and a half years pneumonia. The attacks of asthma had begun at the age of 5, and had occurred at intervals of 14 to 21 days. They began with a cough which was succeeded by difficulty in breathing, and generally started at about 2 A.M., and lasted for 48 hours.

Treatment was commenced on August 10th, 1928, and was followed by a most remarkable improvement in appearance and physique, and he has since (up to June, 1929) had no further attacks of asthma.

CASE 3.—A boy, aged 4 years, was an only child, with a pale face and a flabby and watery body. He was first seen on March 9th, 1927, when he was 2½ years old. There was no family history of asthma or eczema. He had had bronchitis and pneumonia in the previous winter. He was always constipated. When seen he was in a typical attack of bronchial asthma; there was marked prolongation of the expiratory phase and the chest was full of sibilant râles and rhonchi. For the previous nine months he had been having similar attacks at intervals of three weeks.

Treatment was commenced as in the previous cases. A week later he was much better and was able to go out of doors. He has attended hospital since at fortnightly intervals and had had no further attacks of asthma by June 6th, 1929—that is, for a period of two years and three months.

CASE 4.—A boy, aged 4½ years, whose maternal grandmother had suffered from asthma, was an only child, well built, and healthy looking. For the past three years he had suffered from attacks of cough and shortness of breath, mostly commencing during the night, and occurring every two or three weeks, both winter and summer. In some of the attacks he had headaches and vomited, and was said to be feverish. His weight was 2 st. 12 lb. 4 oz.

Treatment with sugar was begun on Feb. 18th, 1928. No further attacks occurred until Dec. 1st, when he had a mild attack. Examination of the urine showed excess of acetone bodies, suggesting that he was for some reason not having sufficient sugar. Renewed instructions as to the importance of treatment were given, and no further attacks have been experienced.

From a consideration of these cases it seems that *an increased allowance of sugar, as such (i.e., not as starchy foods)*, in the diet alone was sufficient to prevent recurrence of asthma in these four children over a considerable period of time. The result justifies the hope that a simple and effective cure and preventive measure has been found for this distressing disorder, at least in some cases. Unfortunately, so far as my experience goes, sugar is without value in the treatment of asthma in adults.

It is not possible to lay down more precise rules for the exact amount of sugar required in a given case. In general it may be said that that amount—ascertained by trial—must be given which will ensure that the urine does not contain an excess of acetone bodies (positive Rothera reaction) under any conditions of stress—i.e., worry, excitement, or infection. In practice, this would generally seem to be met by the doses given in the cases here recorded. The administration of alkalis in these cases does not appear to enhance the action of the sugar in any way.

Sugar in the Treatment of Infantile Eczema.

In view of the supposed connexion between eczema and asthma in children, it is of interest to note that, quite contrary to the usual teaching, sugar also appears to be of some value in the treatment of infantile eczema. This is so subject to spontaneous recovery and remissions that little would be gained by a detailed account of the individual cases treated, but it may be stated that in seven cases of severe infantile eczema, one involving the whole of the head, face, and trunk, glucose added to the feeds or given in lemonade was the only form of treatment employed. No other alteration in the diet was made and in none of the cases was there any local application to the skin, which, where necessary, was covered with changes of dry sterilised lint, lightly bandaged on. Bathing was forbidden. The first result noted was a drying-up of the weeping areas, and this was followed by dropping-off of the scales. None of these cases have been under observation for a sufficient length of time to determine whether or not this therapeutic measure is of any prophylactic value for recurrences of eczema. Nor is it suggested that this procedure gives better results than recognised methods for the treatment of this condition, though it may be of value in some cases in addition to the usual local measures.

These observations form part of an investigation on subnormal children carried out with the aid of a grant from the Medical Research Council.

EMOTION AND ACUTE GLAUCOMA.

By W. S. INMAN, M.B. LOND.,

SENIOR OPHTHALMIC SURGEON, PORTSMOUTH AND SOUTHERN COUNTIES EYE AND EAR HOSPITAL.

FOR many years ophthalmologists have accepted emotion as an exciting cause of acute glaucoma. My own experience has suggested that even though conscious emotion may not be present, at any rate in a sufficient degree to account for the attack of glaucoma, nevertheless the onset may coincide with the anniversary of events once pregnant with emotion but now apparently indifferent or even long since forgotten. The psychological investigation of such cases might lead to a further knowledge of the mechanisms involved, and so enable us sometimes to prevent the development of this very serious and painful disease by providing for the discharge of the emotion through legitimate paths.

I was recently called in to see a retired medical man, aged 77, who had developed acute glaucoma in the left eye the night before. This at first sight seemed to be a case unassociated with any emotional experience. The patient said that he had had no upset on the previous day. He had gone to bed at 10 o'clock and a quarter of an hour later the attack had begun. But I was suspicious. Experience had made me wary of accepting such evidence, and I remarked to the doctor in charge, who knew of my researches, "This is probably a case of periodicity." The patient did not understand the drift of my remark, but his son, who was unusually intuitive, said that he thought he could shed some light on the attack. "Yesterday," he said, "was my birthday, and my father, who has felt recently that he would not live much longer, spent some time last evening in discussing my future after his death." Father and son were living together alone, and the bond between them was very close. The former declared that he had not been worried by the thought of death, but it was clear that he was much concerned about his son's welfare, and had chosen the birthday as the appropriate occasion for the contemplation of the most momentous event which can happen to anyone after birth. There were other matters in the conversation which might have been expected to evoke emotion from the patient, notably that several members of the family had died suddenly, the eldest and last surviving sister having done so at the age of 77. The patient, having now attained this age, thought that he too might die suddenly and wished to assure himself of his Benjamin's happiness before departing.

The patient's nervous state was shown during the operation by great restlessness, although he felt no pain. I intentionally refrained from keeping the other eye under eserine, but no further symptoms arose until two days later, when glaucoma developed. I was anxious not to operate until the left eye was safe, so reassured him, and instilled eserine. Within a few hours the symptoms of glaucoma had disappeared, and they never recurred, though he had no further treatment. A fortnight later it was decided to see what effect dilatation of the pupil would have in order to settle whether a prophylactic trephining should be done. Accordingly, homatropine was instilled after the eye had been carefully examined for any signs of past or present glaucoma. The pupil became dilated until the iris was almost invisible, but the tension remained normal and has done so up to the present, the next anniversary producing no recurrence of the disease.

Thus, in this case at any rate, some factor other than mere mechanical dilatation of the pupil must be invoked to explain why he got glaucoma in the right eye, and it is that factor which needs the most careful investigation. That it frequently depends upon some emotional disturbance is, as I have said, commonly admitted. The circumstances of the onset in the patient's left eye suggest that an attack may replace an emotion, for the strange part of the story is that the father was perfectly calm during the talk with his son and was not conscious of any mental disturbance. The son assured me that it was the custom to talk freely about possible deaths in the family. It had been so during the mother's fatal illness some years previously, and she had then serenely made detailed arrangements with her family for her burial. If, then, the patient felt no ill-effects from the conversation, can we conclude that there was any connexion between it and the ensuing glaucoma? Like all medical questions involving proof, this is difficult to answer. One case does not establish a rule, and the application of statistical methods in psychological investigation is by no means easy.

Space does not permit me to give details of the 20 consecutive cases which have been followed out, but the most striking feature has been the absence of conscious mental stress sufficient to account for the acute attack. Only two followed soon after a death in the family, and the interval in each case was sufficiently long to have allowed the patient's grief to be tempered by time. Indeed, in a long experience, I can call to mind only one instance where acute glaucoma followed immediately upon a death in the family. This was the case of a man who developed the disease whilst returning from the funeral of his mother.

In attempting to explain these strange phenomena, which, as I hope to show in future papers, could be multiplied indefinitely for eye diseases in general, one naturally turns for enlightenment to any psychological theory which might fit in with the facts, and it is with something of a shock that one remembers the emphasis laid by Freud upon the legend of Œdipus, who blinded himself in expiation of his unwitting offences against his parents. It is possible that research will reveal more and more the profound influence of complexes in the determination of organic as well as functional illness. The first case I investigated got acute glaucoma the day before the anniversary of her mother's death 47 years before—a date which she had completely forgotten—and had a recurrence of the symptoms, without actual increase of tension, on her own birthday six months later. Another woman developed an attack on her birthday, while yet another became glaucomatous while fretting over a slight chill which might have prevented her attending her mother's birthday party on the morrow. One man, aged 58, burst into tears when asked about his mother's death, which had occurred within a day or two of the date of his attack of acute glaucoma but with an interval of 48 years.

These patients, amongst others, certainly seem to have lost their sight temporarily in connexion with intimate family relationships of many years' standing. The latter are not consciously of such a nature as ordinarily to produce serious illness, and one must presume the working of an unconscious mental mechanism, unless the associations now recorded are to be attributed to pure coincidence. If the former, then the ophthalmologist must seek the aid of a skilled psychopathologist to arrive at a further elucidation of the problem, for direct questioning may be valueless. There must be many cases of acute glaucoma in which the mechanism necessary for the attack has been set in motion by stimuli other than the recurrence of a certain date. The latter has merely been used as a convenient formula for the purpose of investigation in old people who could not be subjected to direct analysis.

Clinical and Laboratory Notes.

A CASE OF KIENBÖCK'S DISEASE.

ULTIMATE RECOVERY WITHOUT OPERATIVE TREATMENT.

BY E. W. RICHES, *M.C.*, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE HOSPITAL OF ST. JOHN AND ST. ELIZABETH; SURGICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

SEVERAL cases of this somewhat rare condition of traumatic osteoporosis of the carpal semilunar have been described recently.[1] The present case is considered worthy of record, in view of the almost perfect functional recovery after an interval of four years without operative treatment.

The patient, a crane-driver aged 33, who used his right hand to manipulate switches and brakes, was admitted to the Middlesex Hospital on July 20th, 1925, having fallen 30 feet from his crane. The diagnosis made was "compound fracture of left tibia and fibula; 'sprain' of right wrist." The pain in the wrist quickly subsided until after his discharge three months later, when he was using crutches. It then increased gradually, and was severe by March, 1926, when there was swelling and tenderness on the dorsum of the wrist and limitation of all movements. X ray examination showed patches of rarefaction and increased density in the semilunar bone.

Massage and movements were ordered, but caused no improvement. In August, 1926, the wrist was put up in plaster in dorsiflexion for three weeks, followed by massage and radiant heat; this brought about a slight improvement. In October the pain was greatest when at rest, and a cock-up splint was ordered for wear at night. In November an X ray showed some increase of the areas of rarefaction at the expense of those of increased density. In February, 1927, there was still considerable limitation of movement and X rays showed no further changes. In March the hand was manipulated under an anæsthetic; the utmost movement obtained was flexion 45°, extension 35°, adduction 30°, and abduction 0. By September there had been little change. X rays showed the areas of rarefaction now predominating. In December movement and power were limited by 50 per cent.; he could not carry a bucket of water without pain. There was swelling and tenderness over the centre of the dorsum of the wrist and an increase in the antero-posterior diameter, but no crepitation on movement. Pain in the wrist was caused by percussing the heads of the third and fourth metacarpals.

In August, 1929, he had almost completely recovered power, and could lift heavy weights with only occasional pain. He obtained a flexion of 60°, an extension of 45°, an adduction of 45°, and an abduction of 20°, and there was no tenderness, though antero-posterior thickening remained. The X ray showed mainly an increased density of the semilunar, with no arthritic changes in the carpus.

Comments.

This condition was first described by Peste in 1843; in 1910 Kienböck collected 30 cases, and his name has since been associated with the disease.[2] A similar condition of the carpal scaphoid is known as Preiser's disease, and various combinations of carpal bones may be affected, including the os magnum and unciform, as well as the semilunar and scaphoid. Buchman has described seven such multiple cases.[3]

Of Kienböck's 30 cases, 31 were males; in 24 the right wrist was affected, and 23 were between the ages of 17 and 30 years. These proportions are borne out by other observers; Goldsmith states that males are affected seven times as often as females, and the right wrist two and one-half times as often as the left, and that the commonest age of incidence is in the third or fourth decade.[4] Most observers agree that the condition follows trauma, either a single severe pressure insult or repeated small injuries, such as are received in some occupations. Müller describes in addition an anatomical type due to abnormal pressure lines from anatomical anomalies, but this has not been universally accepted. In the present case occupational trauma was present, but the onset was determined by a single violent injury.

There is, as in this case, an initial acute stage lasting for some weeks, with swelling, pain, and tenderness over the semilunar, and limitation of movement. This is followed by an interval of comparative freedom from symptoms, lasting possibly for several months. Increasing disability then becomes manifest, with swelling and tenderness, and the patient is left with a permanent moderate degree of disability.

In addition to the swelling and tenderness over the semilunar and limitation of movement, two "pathognomonic" signs have been described by Finsterer.[5] These are loss of prominence of the third knuckle, due to compression of the semilunar in its vertical axis, and pain in the semilunar on percussing the head of the third metacarpal. This latter sign is present also in some cases of fracture of the carpal bones, and the amount of radial or ulnar deviation of the hand determines which metacarpal must be percussed to give the maximum pain. Radiographic signs are usually negative in the first stage. Subsequently, areas of rarefaction and areas of increased density appear; the bone tends to be compressed vertically and widened antero-posteriorly. The proximal part is usually involved first, and may become fragmented; it is held by some that a fine line of fracture can be seen in cases examined early.

Pathology.

Examination of an excised bone shows that it contains cysts, with loose and dense fibrous tissue invading it. Various theories have been advanced to account for the condition; they may be summarised as follows:—

(*a*) *Those assuming the presence of a fracture.*—(1) Localised osteitis fibrosa in the region of a fracture (Wollenberg). (2) Defective regenerative ability of the carpus (Baum). (3) Aseptic primary bone necrosis with a pathological fracture (Axhausen).

(*b*) *With no assumption of fracture.*—(4) Injury to blood-vessels, due to tearing of the dorsal and lateral ligaments following a momentary dislocation, and followed by rarefaction (Preiser). That this is probably incorrect was pointed out by Ogilvie when showing a case recently at the Medical Society of London; he had followed up cases of dislocated semilunar which were reduced, and none had developed Kienböck's disease. (5) Abnormal pressure due to anatomical anomalies (Müller). (6) Degeneration (Destot). (7) Infection (Fontaine). (8) Leriche assumes that there can be no rarefaction without hyperæmia, and suggests a traumatic axone reflex, the sequence being trauma, vaso-constriction, vaso-dilatation, bone absorption.

In considering the possibility of an initial fracture, it must be remembered that fracture of the semilunar bone alone is very rare; Goldsmith reports only 14 cases in 13,143 fractures of all bones, or 0·1 per cent.[4] It is also difficult to conceive of any mechanism by which the semilunar alone can sustain a "crush" fracture without injury to other carpal bones.

The condition cannot be regarded as similar to Schlatter's disease, pseudo-coxalgia, or Köhler's disease of the tarsal scaphoid, all of which occur in the growth period. Henderson suggests Kümmell's disease of the spine as the nearest analogy.[7]

Prognosis for complete cure is not good; osteo-arthritis may develop as a sequela.

by a detailed account of the individual cases treated, but it may be stated that in seven cases of severe infantile eczema, one involving the whole of the head, face, and trunk, glucose added to the feeds or given in lemonade was the only form of treatment employed. No other alteration in the diet was made and in none of the cases was there any local application to the skin, which, where necessary, was covered with changes of dry sterilised lint, lightly bandaged on. Bathing was forbidden. The first result noted was a drying-up of the weeping areas, and this was followed by dropping-off of the scales. None of these cases have been under observation for a sufficient length of time to determine whether or not this therapeutic measure is of any prophylactic value for recurrences of eczema. Nor is it suggested that this procedure gives better results than recognised methods for the treatment of this condition, though it may be of value in some cases in addition to the usual local measures.

These observations form part of an investigation on subnormal children carried out with the aid of a grant from the Medical Research Council.

EMOTION AND ACUTE GLAUCOMA.

BY W. S. INMAN, M.B. LOND.,

SENIOR OPHTHALMIC SURGEON, PORTSMOUTH AND SOUTHERN COUNTIES EYE AND EAR HOSPITAL.

FOR many years ophthalmologists have accepted emotion as an exciting cause of acute glaucoma. My own experience has suggested that even though conscious emotion may not be present, at any rate in a sufficient degree to account for the attack of glaucoma, nevertheless the onset may coincide with the anniversary of events once pregnant with emotion but now apparently indifferent or even long since forgotten. The psychological investigation of such cases might lead to a further knowledge of the mechanisms involved, and so enable us sometimes to prevent the development of this very serious and painful disease by providing for the discharge of the emotion through legitimate paths.

I was recently called in to see a retired medical man, aged 77, who had developed acute glaucoma in the left eye the night before. This at first sight seemed to be a case unassociated with any emotional experience. The patient said that he had had no upset on the previous day. He had gone to bed at 10 o'clock and a quarter of an hour later the attack had begun. But I was suspicious. Experience had made me wary of accepting such evidence, and I remarked to the doctor in charge, who knew of my researches, "This is probably a case of periodicity." The patient did not understand the drift of my remark, but his son, who was unusually intuitive, said that he thought he could shed some light on the attack. "Yesterday," he said, "was my birthday, and my father, who has felt recently that he would not live much longer, spent some time last evening in discussing my future after his death." Father and son were living together alone, and the bond between them was very close. The former declared that he had not been worried by the thought of death, but it was clear that he was much concerned about his son's welfare, and had chosen the birthday as the appropriate occasion for the contemplation of the most momentous event which can happen to anyone after birth. There were other matters in the conversation which might have been expected to evoke emotion from the patient, notably that several members of the family had died suddenly, the eldest and last surviving sister having done so at the age of 77. The patient, having now attained this age, thought that he too might die suddenly and wished to assure himself of his Benjamin's happiness before departing.

The patient's nervous state was shown during the operation by great restlessness, although he felt no pain. I intentionally refrained from keeping the other eye under eserine, but no further symptoms arose until two days later, when glaucoma developed. I was anxious not to operate until the left eye was safe, so reassured him, and instilled eserine. Within a few hours the symptoms of glaucoma had disappeared, and they never recurred, though he had no further treatment. A fortnight later it was decided to see what effect dilatation of the pupil would have in order to settle whether a prophylactic trephining should be done. Accordingly, homatropine was instilled after the eye had been carefully examined for any signs of past or present glaucoma. The pupil became dilated until the iris was almost invisible, but the tension remained normal and has done so up to the present, the next anniversary producing no recurrence of the disease.

Thus, in this case at any rate, some factor other than mere mechanical dilatation of the pupil must be invoked to explain why he got glaucoma in the right eye, and it is that factor which needs the most careful investigation. It is possible that research will reveal more and more the profound influence of complexes in the determination of organic as well as functional illness. The first case I investigated got acute glaucoma the day before the anniversary of her mother's death 47 years before—a date which she had completely forgotten—and had a recurrence of the symptoms, without actual increase of tension, on her own birthday six months later. Another woman developed an attack on her birthday, while yet another became glaucomatous while fretting over a slight chill which might have prevented her attending her mother's birthday party on the morrow. One man, aged 58, burst into tears when asked about his mother's death, which had occurred within a day or two of the date of his attack of acute glaucoma but with an interval of 48 years.

These patients, amongst others, certainly seem to have lost their sight temporarily in connexion with intimate family relationships of many years' standing. The latter are not consciously of such a nature as ordinarily to produce serious illness, and one must presume the working of an unconscious mental mechanism, unless the associations now recorded are to be attributed to pure coincidence. If the former, then the ophthalmologist must seek the aid of a skilled psychopathologist to arrive at a further

GENERAL MEDICAL COUNCIL.

PENAL CASES.

TUESDAY, NOV. 26TH.

ACCORDING to custom, the Council heard the cases in public, deliberated upon them in camera, and the President then announced the decision.

Reported from the Dental Board.

The Case of James Ireland, registered as of "Buena Vista," Costock, Nottinghamshire, "Dentist 1921."

In May, 1928, Mr. Ireland had been summoned by the Board to attend an inquiry in respect of convictions for (*a*) being drunk whilst in charge of a motor-car, (*b*) of driving a motor-car in a manner dangerous to the public, and (*c*) of being drunk and disorderly. The convictions were found proved, but judgment was postponed for six months. In November, 1928, the case was discharged, and Mr. Ireland gave his assurance that he would do his best to justify the leniency of the Board. He was informed that if he had to appear before the Board again, the result might be very serious. On May 29th, 1929, however, he was again convicted at the Nottingham police-court of being drunk and disorderly, and was fined 10s. He sent a letter to the Board's solicitor that he was not intoxicated or disorderly at the time, but was upset and excited owing to the loss of his money which had been picked from his pocket while waiting for a 'bus. He said he could not attend the inquiry owing to an injury to his leg in August last, when he was run down by a motor-car, and the consequent expense. He was asked to send a medical certificate of inability to attend, and thereupon submitted one dated August 21st, 1929, given him at the time of the accident, which stated that he was at that time disabled from following his employment. The police reported that when Mr. Ireland was arrested he was drunk and wanted to fight anyone near him.

The Dental Board had found the conviction proved, and advised that Mr. Ireland's name should be erased from the Register.

Mr. Ireland sent a letter pleading the hardship involved to his family if his name were erased. The Council directed the Registrar to remove his name.

The Case of Mihrane Haroutune Chirinian, registered as of 26, Coventry-street, London, W.1, "Dentist 1921."

He had at the County of London Sessions commencing on April 9th, 1929, been convicted (in the name of Mihrank Haroutin Chirinian) of stealing one suit-case and other articles, the property of Violet Gutteridge; one suit, the property of Airey and Wheeler; 34 pairs of silk stockings, the property of Etams, Limited; and one gold cigarette case, the property of Elkington and Company; and sentenced to three years' penal servitude and recommended for deportation. The Chairman of Session in passing sentence had said it was plain that Chirinian was a dangerous and dishonest man, who preyed upon everybody with whom he came in contact. Respondent had applied to the Court of Criminal Appeal for leave to appeal against the conviction, and the application had been dismissed. He had sent letters to the Board's solicitor and to the Registrar of the Board from H.M. Prison, Parkhurst, denying that he was guilty of the offences, and asking for a postponement of the inquiry until he was released from prison. He complained of not being given time enough to petition to the Home Secretary for permission to attend the inquiry, and his inability to engage a lawyer. The notice of inquiry had been sent to Mr. Chirinian on Oct. 17th, 1929, thus giving him ample time to apply to the Home Office and to engage a lawyer, provided he had the means for the latter.

The Board had found the conviction proved, and had recommended that the name of Mihrane Haroutune Chirinian be erased from the Register. Mr. Chirinian did not attend and was not represented. The Council directed the Registrar to erase his name.

Restorations to the Dental Register; Dental Education.

After further deliberation in camera the President announced that the following names had been restored to the Dental Register: Laurent Eugène Doprimoz and William Laird.

The Council then received and adopted the report of the Dental Education and Examination Committee. The University of Adelaide, Mr. Dolamore said, had now complied with the requirements of the Committee and it was therefore recommended that the degrees of B.D.S. and D.D.Sc. Adelaide be recognised as entitling to registration on the Colonial list. The Committee had observed that not all degrees in Great Britain and Northern Ireland and the Irish Free State were recognised as entitling to registration in South Australia. They also noted that persons whose names appear on the Dentists Register with a British degree or licence are required to pass a practical test in New South Wales. They desired that the attention of the authorities should be drawn to these anomalies. Conversations had taken place with a representative of the Japanese Embassy, and after careful inquiry the Committee was satisfied that the differences between the Japanese system of dental education and the British were so fundamental that it was not possible to permit Japanese dental qualifications to entitle the holder to registration in this country.

Mr. J. W. McGowan and Mr. E. L. Sheridan were appointed members of the Dental Education and Examination Committee in place of Mr. Guy and Mr. Ackland.

The Council considered in camera the *Case of James Edgar Nelson*, reported by the Dental Board, and the President announced that the case was to be remitted to the Board for further inquiry and report.

Medical Case Adjourned from November, 1928.

The Case of Bertie Edward Acland, registered as of 120, Leonard-road, Birches Head, Hanley, Stoke-on-Trent, M.B., Ch.B., 1924, U. Liverpool, who had previously appeared before the Council on the following charge:—

> "That you were convicted at the Hanley petty sessions of the following misdemeanours—viz.: (1) On July 22nd, 1926, of being drunk in charge of a motor-car, and were fined £10 and witness fee £1 1s., or two months' imprisonment in default; and (2) on Oct. 2nd, 1928, of being drunk in charge of a motor-car, and were fined £20 and witnesses' fees £2 1s., and were disqualified for holding a driving licence for two years."

Last year the Council had postponed judgment. Mr. Acland appeared, and the Council's solicitor read letters from his professional brethren testifying to his sobriety during the past year and from the police authorities saying that there had been no further conviction against him. Mr. Acland spoke of the increase of his panel practice and assured the Council of his intention to abstain from alcoholic excess in future. The Council decided not to erase his name from the Register.

An Erasure for Immoral Relations with a Patient.

The Case of Angus Dugald Buchanan, registered as c/o Messrs. Crawford Herron and Cameron, 257, West George-street, Glasgow, C. 2, M.B., Ch.B. 1911, Glasg., who had been summoned to appear before the Council on the following charge:—

> "That, being a registered medical practitioner, you abused your position by committing adultery with Elizabeth McCarron or Campbell, whom and whose family you had attended professionally, subsequent to which you were co-defender in the case of Campbell *v.* Campbell and Buchanan in the Court of Session, in which proceedings a decree of divorce was pronounced on Nov. 9th, 1928. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

Mr. Harper, the Council's solicitor, said that there was no complainant in this case, but the facts had been brought before the Council by Mr. Campbell. Adultery and professional relationship had been set out in the divorce proceedings, but the professional relationship was now emphatically denied and the respondent claimed that Mr. Campbell had known of the relationship and had shared in large sums of money paid by respondent to Mrs. Campbell. Dr. Buchanan had not contested the divorce proceedings but had left for Australia; he now maintained that the proof of the Campbell's doctor. She had introduced them in her own house in a friendly way, not in the least professionally. In 1926 Mrs. Campbell had confessed that the relations were and always had been guilty, and that they had started from a meeting in the street out of surgery hours. Mrs. Campbell had then said that she intended to squeeze the doctor dry and keep him in her hand till she had, and that her separation from Mr. Campbell had been due to her relationship with the doctor. After 1926 new furniture and new clothes had appeared. The neighbours had been outraged by her conduct. Dr. Buchanan had called openly in the forenoon. Witness had never nursed Mrs. Campbell, and had never been in the house as a paid charwoman or servant. She had followed Mrs. Campbell, and had seen her meet the doctor on several occasions in different streets; she had set off at twenty to three every day and returned about six. She had followed Mrs. Campbell and seen her meet the doctor every day for about three months.

Mr. Henderson put in a sworn statement sent by Dr. Angus Buchanan from Australia. He stated that he was married and had three children under 14. He confirmed the material facts of the case and declared that he had been introduced to Mrs. Campbell by a Mrs. Johnstone. Their relationship had been purely social. Mrs. Campbell had first suggested intercourse and had threatened to expose the affair to his wife when he had tried to break it off. She had demanded money and received about £2 a week for two years. When he had told her he was going on a holiday she had declared he should not go unless he paid for a holiday for her. Her demands had become more insistent and finally he had told his wife all about it. He had at no time acted as medical adviser to Mrs. Campbell or her family.

Mr. Henderson addressed the Council, submitting that the case against his client had not been proved, that the affair was simply that of a paid mistress who was willing to do her best to ruin the man who had discarded her. The evidence for professional relationship was confined to the relatives and rested on the question of medicines. It was quite true that medicines could have been made up by the practitioners themselves, but the evidence of these relatives was that the medicines had been made up by the dispenser, and the money tendered to him on many occasions. It was incredible that the name of Mrs. Campbell should invariably have been omitted from the books by that dispenser, years ago, before any question of proceedings had arisen. Mrs. Campbell's meeting with Dr. Buchanan had nothing to do with the fact that her daughter had previously joined the panel of his partner. By the time the son joined Dr. Buchanan's panel the relationship had existed for two years.

Mr. Harper briefly addressed the Council. After deliberation in camera the President announced that the Council had found the charge proved to their satisfaction, and directed that the name of Dr. A. D. Buchanan be erased from the Register.

Advertising in India.

On Wednesday, Nov. 27th, the Council considered *the Case of Ratilal Shivlal Shah*, registered (Colonial List) as c/o Umjamshi S. Shah, High Court Pleader, Rajkot, India, M.B., B.S. 1922, U.Bombay, who had been summoned to appear before the Council on the following charge:—

> "That, being a registered medical practitioner, you have advertised for the purpose of obtaining patients or promoting your own professional advantage—viz.: (1) By the issue of two leaflets in respect of two medicines concocted by you, to wit 'Shwetanjan' and 'Muktanjan.' (2) By calling your private home or dispensary 'Dr. Shah's Eye Hospital' or 'Dr. Shah's Ophthalmic Hospital.' (3) By inserting, or sanctioning the insertion, or acquiescing in the insertion, in the March, 1928, number of a Gujarati paper called *Sharda* of an advertisement of the above-mentioned remedies. (4) By inserting, or sanctioning the insertion, or acquiescing in the insertion, on another page of the issue of the said paper *Sharda*, a portrait of yourself with a laudatory notice below such portrait. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Council's attention had been drawn to this case by the Bombay Medical Council. Mr. Shah did not attend but was represented by Mr. H. F. Parfitt, of Messrs. Minet, May and Co., solicitors. The Council's solicitor related the facts, and both solicitors addressed the Council. After deliberation in camera the President announced the decision of the Council as follows:—

> "I have to announce that the Council have decided that they will not now proceed to decide whether the facts alleged against Mr. Shah in this notice of inquiry have been proved or have not been proved, on the ground that the materials for a decision are insufficient. They will, therefore, ask you both to appear in November of next year, and to bring up further evidence, Mr. Harper from the Bombay Medical Council, and Mr. Parfitt, on behalf of Mr. Shah, if he has anything further to say then."

The Council received a report from the Executive Committee that the name of Ewen Cameron McLeod had been removed from the Register of the College of Physicians and Surgeons of Manitoba. The Committee was satisfied that Mr. McLeod had not been deprived of his qualification on the ground of his adoption of any theory of medicine and surgery. It was moved by the Chairman of Business, seconded by Sir John Moore, and agreed that the name of Mr. McLeod be removed from the Register in respect of the qualification of M.C.P. & S. Man. 1926, therein recorded.

Restorations.

The President announced that the Registrar had been directed to restore to the Medical Register the names of Bernard Wilfred Goldstone and David Davey Rosewarne.

Association of a Practitioner with a Company Trading in Secret Remedies.

The Case of John Forrest Hamilton, registered as of Mexborough House, Mexborough, Yorks, M.B., Ch.B., U.Glasg., 1919, who was summoned to appear before the Council on the following charge:—

> "That, being a registered medical practitioner: (1) you have associated with a person or persons (unqualified) for the purpose of treating persons in respect of matters requiring professional discretion or skill; (2) having acquired a part interest in certain secret remedies, preparations, and medicines from unregistered persons, you are engaged in association with them in the sale for your own profit of such secret remedies, preparations, and medicines. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The complainants were the Medical Defence Union, represented by Mr. Oswald Hempson. Respondent appeared in answer to his notice.

Mr. Hempson read out the prospectus of a company called "Lunvitre, Ltd.," of which the address was that of Dr. Hamilton, and of which Dr. Hamilton was a director. The memorandum of association showed that Dr. Hamilton was associated with two other directors, one of them a miner, and that the objects of the association were to acquire and trade in secret preparations and medicines for the treatment of tuberculosis of the lungs and other disorders, and such other secret preparations as seemed fit to the company. Another document was signed by Dr. Hamilton as secretary of the company. Part of the defence was that no trade had been carried out. The Medical Defence Union had no interest in waiting until the offence had become indisputable; as soon as they heard of the intention they placed the matter before the Council for a ruling. Mr. Hempson argued that it was infamous for a professional man to have any interest in the sale of medicines, particularly for a disease like tuberculosis, where general treatment was of such importance. A Mr. Webster, chemist, had written to the company about the "Lunvitre" treatment for tuberculosis, and had received a reply signed by "J. Hamilton." The reply was typewritten on business notepaper with all the usual company notices in its letterhead and a highly coloured representation of a Red Indian's head. The letter undertook to execute a commission in a month's time, and claimed marvellous results for the medicine, referring to "hundreds of testimonials." In his defence Dr. Hamilton had quoted from correspondence with his lawyer and with the British Medical Association, but had torn his quotations from their context. The Registrar had written to Dr. Hamilton in August, 1929, warning him that association with the proposed company would be highly undesirable for a registered practitioner. Dr. Hamilton had replied at some length on Sept. 18th, 1929, admitting that he was chairman of directors of a limited company, but maintaining that no harm had been done since trading had not yet been commenced, and that his position was comparable with that of any doctor holding shares in a trading concern. He declared that he would not prescribe for his own patients any product marketed by the company. On Sept. 19th the Registrar had replied as follows:—

"J. F. Hamilton, Esq., M.B.

"DEAR SIR,—In reply to your letter of Sept. 13th, I regret if it appears that mine of the 27th ult. was not sufficiently clear. There are certain practices which, without bringing a medical man within the precise terms of the warning notices, may nevertheless be considered contrary to the best interests of the profession, and to be deprecated by his fellow practitioners of good repute and competency. Amongst these has been considered the pledge of secrecy where the composition of remedies is concerned, and the association, whether openly or otherwise, with a concern devoted to their manufacture.

"The Council have never attempted to control the field of investments open to a medical practitioner, but, without introducing any element of compulsion into their opinion, they feel that in the best interests of the profession it would be wiser for a medical practitioner to seek a return for his capital in directions other than patent medicines. If, notwithstanding, he is determined to keep up his connexion with a proprietary company, he is, at least requested to see that no use is made of his name and qualifications upon official stationery, nor that his name and qualifications are made use of for the purpose of advertising the products.

"Should your association with the direction of the proprietary medicine company become known to your professional colleagues, you will almost certainly be made aware of their disapproval, and may probably be made subject to complaints to the Council regarding your action. The legal fact that the company is technically a separate entity would not protect you against such complaints.

"Yours faithfully,

"NORMAN KING,

"Registrar."

The Medical Secretary of the British Medical Association had noticed the company's advertisement and had written to Dr. Hamilton, as a member, warning him that it was contrary to all tradition that a medical man should have any interest in the sale of patent medicines. An accountant had replied on behalf of Dr. Hamilton on Sept. 9th arguing in justification: (1) that the company was a separate legal entity; (2) that Dr. Hamilton had never proposed to take any step which would bring business to the company by virtue of his medical degrees; (3) that the company did not propose to use as advertisement the fact that one of the directors was a medical man. The Medical Secretary had replied that in view of the general opinion of the profession he was sorry that Dr. Hamilton had taken this position, although the safeguards would appear to meet any objections of the General Medical Council.

Dr. J. Neal, Secretary of the Medical Defence Union, testified to his statutory declaration confirming the facts set out by Mr. Hempson and the steps taken by the Union to investigate them.

Cross-examined by Dr. Hamilton, Dr. Neal said that it was not necessarily derogatory for a medical man to hold shares in a trading firm or, further, to have some say in its direction.

Re-examined, he explained that the nature of the company and to a lesser extent the degree of the association would influence his opinion about the association of a medical man with a company.

Mr. T. Gething, an accountant, of Mexborough, testified to his declaration describing how he had bought a bottle of "Lunvitre" from Mr. G. H. Jones, who had told him that the company had also remedies for rheumatism and gall-stones which would be on sale the following week. He had also said that Dr. Hamilton's coachhouse and stables had been converted into a factory, and that as Dr. Hamilton knew where to get the drugs the cost was reduced. An old lady and a man had been present at this interview. He declared that 105, Market-street was Dr. Hamilton's private address, and produced the entry in the Voter's Register in confirmation. There was no plate on the door of that house. Mr. Jones had said that the cure had been given to him by an old Indian in Canada, and the Indian's head would be the trade-mark of the company's products.

Cross-examined, Mr. Gething denied that he was collector for a firm of doctors who had been asked by Messrs. Hempson to collect evidence, and denied that he had a grudge against Dr. Hamilton as a result of accusations brought about him some years ago. He had never heard any doctor say it would be worth £500 to him to get Dr. Hamilton out of Mexborough. He had gone to Mr. Jones's house about a debt with which he was dealing and had spoken about that account before mentioning "Lunvitre." He reiterated the statements in his declaration, particularly that Mr. Jones had said that both he and Dr. Hamilton saw patients. Mr. Jones had not made the bottle up for him as a favour; it had been already made up.

The bottle was produced. The label contained the words, "The great remedy for all lung troubles. Manufactured solely by G. E. Jones, 40, Doncaster-road, Mexborough."

Mr. Sinclair, M.P.S., deposed that he was a chemist and had traded with Mr. G. E. Jones for two or three years. Mr. Jones had purchased pure glycerin, syrup of mulberry, oil of juniper, Friar's balsam, and sal volatile. The first two were ingredients for the "cure." Since the company had been formed, Mr. Jones had told him that the recipe was obtained from an American Indian, and that an Indian was to appear on the label. He had referred to a film which had been prepared to advertise the remedy, and said he had entered into partnership with Dr. Hamilton for the preparation of the remedy, its factory to be at 105, Market-street. Witness was familiar with Dr. Hamilton's signature on prescriptions, and thought the signature on the letter from "Lunvitre, Ltd.," closely resembled his, though the initials were not quite as usual.

Cross-examined, he asserted that Mr. Jones had repeatedly used the word "cure." He had supplied Mr. Jones with glycerin and syrup within the last seven days. He denied ever discussing the cure with respondent.

In reply to the Legal Assessor, he said there were some outbuildings attached to 105, Market-street.

The Defence.

Dr. Hamilton gave evidence on his own behalf. He declared that for eight years he had been persecuted by a medical partnership who, he believed, were the informants in this case. This firm had complained to the Medical Defence Union eight years ago that respondent was touting for patients. The Union had, however, failed to get evidence. The firm had complained to the local ethical medical society and had had him boycotted in his absence; after investigation he had been completely cleared and invited to join the society. An attempt had been made to exclude him from the local hospital by underhand means. He had been approached by Mr. Jones, a patient of his, who had asked for help. Out of sympathy, respondent had offered to give him a chance, intending to get out of it as soon as Mr. Jones the Campbell's doctor. She had introduced them in her own house in a friendly way, not in the least professionally. In 1926 Mrs. Campbell had confessed that the relations were and always had been guilty, and that they had started from a meeting in the street out of surgery hours. Mrs. Campbell had then said that she intended to squeeze the doctor dry and keep him in her hand till she had, and that her separation from Mr. Campbell had been due to her relationship with the doctor. After 1926 new furniture and new clothes had appeared. The neighbours had been outraged by her conduct. Dr. Buchanan had called openly in the forenoon. Witness had never nursed Mrs. Campbell, and had never been in the house as a paid charwoman or servant. She had followed Mrs. Campbell, and had seen her meet the doctor on several occasions in different streets; she had set off at twenty to three every day and returned about six. She had followed Mrs. Campbell and seen her meet the doctor every day for about three months.

Mr. Henderson put in a sworn statement sent by Dr. Angus Buchanan from Australia. He stated that he was married and had three children under 14. He confirmed the material facts of the case and declared that he had been introduced to Mrs. Campbell by a Mrs. Johnstone. Their relationship had been purely social. Mrs. Campbell had first suggested intercourse and had threatened to expose the affair to his wife when he had tried to break it off. She had demanded money and received about £2 a week for two years. When he had told her he was going on a holiday she had declared he should not go unless he paid for a holiday for her. Her demands had become more insistent and finally he had told his wife all about it. He had at no time acted as medical adviser to Mrs. Campbell or her family.

Mr. Henderson addressed the Council, submitting that the case against his client had not been proved, that the affair was simply that of a paid mistress who was willing to do her best to ruin the man who had discarded her. The evidence for professional relationship was confined to the relatives and rested on the question of medicines. It was quite true that medicines could have been made up by the practitioners themselves, but the evidence of these relatives was that the medicines had been made up by the dispenser, and the money tendered to him on many occasions. It was incredible that the name of Mrs. Campbell should invariably have been omitted from the books by that dispenser, years ago, before any question of proceedings had arisen. Mrs. Campbell's meeting with Dr. Buchanan had nothing to do with the fact that her daughter had previously joined the panel of his partner. By the time the son joined Dr. Buchanan's panel the relationship had existed for two years.

Mr. Harper briefly addressed the Council. After deliberation in camera the President announced that the Council had found the charge proved to their satisfaction, and directed that the name of Dr. A. D. Buchanan be erased from the Register.

Advertising in India.

On Wednesday, Nov. 27th, the Council considered *the Case of Ratilal Shivlal Shah*, registered (Colonial List) as c/o Umjamshi S. Shah, High Court Pleader, Rajkot, India, M.B., B.S. 1922, U.Bombay, who had been summoned to appear before the Council on the following charge:—

> "That, being a registered medical practitioner, you have advertised for the purpose of obtaining patients or promoting your own professional advantage—viz.: (1) By the issue of two leaflets in respect of two medicines concocted by you, to wit 'Shwetanjan' and 'Muktanjan.' (2) By calling your private home or dispensary 'Dr. Shah's Eye Hospital' or 'Dr. Shah's Ophthalmic Hospital.' (3) By inserting, or sanctioning the insertion, or acquiescing in the insertion, in the March, 1928, number of a Gujarati paper called *Sharda* of an advertisement of the above-mentioned remedies. (4) By inserting, or sanctioning the insertion, or acquiescing in the insertion, on another page of the issue of the said paper *Sharda*, a portrait of yourself with a laudatory notice below such portrait. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Council's attention had been drawn to this case by the Bombay Medical Council. Mr. Shah did not attend but was represented by Mr. H. F. Parfitt, of Messrs. Minet, May and Co., solicitors. The Council's solicitor related the facts, and both solicitors addressed the Council. After deliberation in camera the President announced the decision of the Council as follows:—

> "I have to announce that the Council have decided that they will not now proceed to decide whether the facts alleged against Mr. Shah in this notice of inquiry have been proved or have not been proved, on the ground that the materials for a decision are insufficient. They will, therefore, ask you both to appear in November of next year, and to bring up further evidence, Mr. Harper from the Bombay Medical Council, and Mr. Parfitt, on behalf of Mr. Shah, if he has anything further to say then."

The Council received a report from the Executive Committee that the name of Ewen Cameron McLeod had been removed from the Register of the College of Physicians and Surgeons of Manitoba. The Committee was satisfied that Mr. McLeod had not been deprived of his qualification on the ground of his adoption of any theory of medicine and surgery. It was moved by the Chairman of Business, seconded by Sir John Moore, and agreed that the name of Mr. McLeod be removed from the Register in respect of the qualification of M.C.P. & S. Man. 1926, therein recorded.

Restorations.

The President announced that the Registrar had been directed to restore to the Medical Register the names of Bernard Wilfred Goldstone and David Davey Rosewarne.

Association of a Practitioner with a Company Trading in Secret Remedies.

The Case of John Forrest Hamilton, registered as of Mexborough House, Mexborough, Yorks, M.B., Ch.B., U.Glasg., 1919, who was summoned to appear before the Council on the following charge:—

> "That, being a registered medical practitioner: (1) you have associated with a person or persons (unqualified) for the purpose of treating persons in respect of matters requiring professional discretion or skill; (2) having acquired a part interest in certain secret remedies, preparations, and medicines from unregistered persons, you are engaged in association with them in the sale for your own profit of such secret remedies, preparations, and medicines. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The complainants were the Medical Defence Union, represented by Mr. Oswald Hempson. Respondent appeared in answer to his notice.

Mr. Hempson read out the prospectus of a company called "Lunvitre, Ltd.," of which the address was that of Dr. Hamilton, and of which Dr. Hamilton was a director. The memorandum of association showed that Dr. Hamilton was associated with two other directors, one of them a minor, and that the objects of the association were to acquire and trade in secret preparations and medicines for the treatment of tuberculosis of the lungs and other disorders, and such other secret preparations as seemed fit to the company. Another document was signed by Dr. Hamilton as secretary of the company. Part of the defence was that no trade had been carried out. The Medical Defence Union had no interest in waiting until the offence had become indisputable; as soon as they heard of the intention they placed the matter before the Council for a ruling. Mr. Hempson argued that it was infamous for a professional man to have any interest in the sale of medicines, particularly for a disease like tuberculosis, where general treatment was of such importance. A Mr. Webster, chemist, had written to the company about the "Lunvitre" treatment for tuberculosis, and had received a reply degrading or dishonourable to his profession. There had been no evidence of any sale of medicines with the knowledge and consent of the company. He quoted again the letter to the accountant from the Secretary of the British Medical Association saying, "I have carefully considered the points you raise, and the safeguards which Dr. Hamilton has taken seem to me pretty adequately to cover any objection which might be taken by the General Medical Council." He humbly submitted that the Council was in honour bound by the letter of its executive officer. Respondent had definitely asked whether his association with the company would be regarded by the Council as infamous conduct in a professional respect. The Registrar had replied in a manner which respondent had unhesitatingly interpreted as a negative. This case was without precedent, and it was very difficult for a young practitioner to determine what might and might not be done. The scheme had been foolishly and carelessly undertaken; but he had acted in good faith, and had taken advice from a chartered accountant and a solicitor. If they had been right, that was his justification; if they had been wrong it showed the difficulty of finding out the Council's wishes. No matter what the decision of the Council, he would sever all connexion with the company.

Mr. Hempson addressed the Council. The respondent had, he said, been warned both by the British Medical Association and by the Registrar. Dr. Cox's letter had been addressed to the accountant, and under those circumstances might well hesitate to use the strong terms of condemnation that might be directed to the doctor himself. Jones had admitted that the letter to the chemist had been written from a draft, and it was obvious that the draft had not been composed by Jones. In Mr. Hempson's opinion the original defence was not an honest one; Dr. Hamilton had not at first realised the seriousness of his position. A more heinous case of association with unqualified practice could not be conceived. Dr. Hamilton had put up money to help a well-known quack to exploit a secret remedy for one of the most fell diseases in this country, and thus to prevent people from getting adequate treatment. While the charge as a whole had been denied, every point in it had been separately admitted.

The President announced that the Council had found the charge proved to their satisfaction and had directed the Registrar to erase Dr. Hamilton's name.

Alleged Canvassing.

The Case of Nagib Iskander, registered as of 96, Primrose-lane, Hall Green, Birmingham, M.B., Ch.B., 1920, U.Birm., who had been summoned to appear before the Council on the following charge:—

> "That, being a registered medical practitioner, you have systematically canvassed for patients by means of agents, and in particular: (1) on or about March 1st and April 29th, 1929, so canvassed Mrs. Elizabeth Howell; (2) on or about March 21st, 1929, so canvassed Mrs. Gladys Martin; (3) on or about March 21st, 1929, and about a week after, so canvassed Mrs. Emily Hall; (4) on or about April 18th, 1929, so canvassed Mrs. Dora Lilian Harrison; and (5) on or about April 20th, 1929, so canvassed Mrs. Gwendoline Ruth Morgan; and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were Mr. V. A. Goldman, M.R.C.S. Eng., Mr. P. Carroll, L.R.C.P. Edin., and Mr. C. C. Blair, M.B. Glasg., represented by Mr. Goldman. Mr. Iskander attended in answer to his notice, accompanied by Mr. Davis, of Messrs. Bulcraig and Davis, solicitors. Mr. Goldman proceeded to lay the facts before the Council, and read five statutory declarations from the five ladies mentioned in the charge; none of them was present.

At this point the President, having consulted the Legal Assessor and the Council, announced that there was no evidence connecting the charges with Mr. Iskander, and the case was dismissed.

(*To be continued.*)

Medical Societies.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

AT a meeting of this Society in London on Nov. 29th, with Dr. F. J. H. COUTTS, the President, in the chair, papers on the

Urinary Excretion of Novarsenobillon in Syphilis, and its Relation to Toxic Effects

were read by Dr. N. L. LLOYD and Mr. V. E. LLOYD. Despite the wide use of salvarsan and its derivatives during the last 15 years, said Dr. Lloyd, the fate of these compounds in the body was not yet fully understood, though it was known that a considerable proportion of them was excreted soon after injection, principally in the urine and fæces. The inter-relation of intensity of therapeutic effect, rate of elimination, and toxic manifestations was of considerable importance. There was now a good deal of evidence of deterioration of hepatic efficiency following the use of these compounds; jaundice sometimes appeared, and might continue even after treatment was stopped. The chief aim in treating syphilis was to attain the maximal therapeutic action with the minimum of toxicity. At the beginning of treatment any reliable test which would reveal patients who were specially susceptible to toxic effects must be of value in deciding dosage. One of the practical objections to the present tests was that they took so much time that employers had to know why abstention from work was necessary. Accordingly Dr. Lloyd and his brother had been led to use a colour reaction, described by Abelin in 1911, which was very simple and did not need any special apparatus. Abelin's test depended on the conversion of the arsenobenzol into a diazo compound and the subsequent linking of this body to some member of the phenol or naphthol groups with development of a colour. Patients receiving salvarsan showed its presence in the urine five to ten minutes after injection, and Abelin had demonstrated that excretion continued as long as seven hours. Elimination was found to be more prolonged in tertiary syphilis and neurosyphilis. Absence of elimination should lead to careful examination of the patient before going on with treatment. Several workers had shown, however, that the rate of excretion did not decline in regular progression. It was noted that the drug disappeared rapidly from the blood stream, but it could not be demonstrated in the cerebro-spinal fluid except after massive doses in dogs. The fæces gave negative reactions.

In outline the test was as follows:—

> Five c.cm. of the fluid to be examined was placed in a test-tube and cooled in running water or ice. To this was added 0·5 c.cm. of 5 per cent. hydrochloric acid, and after a few minutes 1 c.cm. of a 0·5 per cent. solution of sodium nitrite. The solution was kept in running cold water for ten minutes. In a second test-tube was placed 4 c.cm. of a 10 per cent. solution of resorcin in water and 1 c.cm. of 10 per cent. sodium hydroxide. Then the contents of the first test-tube were added to those of the second tube. The presence of arsenobenzol was shown by the development of a colour which varied from red to reddish-brown, and this colour appeared immediately. Experiments showed that a red colour developed in watery solutions of a strength of 1 in 20,000. By looking through a depth of fluid of 5 cm. with transmitted light, a positive result could be seen in a dilution of 1 in 100,000. With urine, however, one could not be sure of a definite result in a higher dilution than 1 in 50,000.

It was not essential that the urine should be tested immediately it was passed; urine left as long as ten days gave as good a result as immediately after it was voided. The following organic preparations, tested in vitro in a strength of 1 in 1000, had given markedly positive results: novarsenobillon (N.A.B.), metarseno-argenticum, metarsenobillon, stabilarsan, sodium silver salvarsan, kharsulphan, sulpharsenol. Results were negative with watery solutions of atoxyl, stovarsol, tryparsamide, bistovol, and neobistovol. The investigation of phenacetin had proved interesting. In vitro no colour developed, but the urine voided up to a period of three to four hours after an oral dose of grs. 15 phenacetin gave an almost identical red colour with this test. In short, Abelin's test was reliable but not absolutely specific. It did not indicate the presence of arsenic.

Mr. V. E. **Lloyd** dealt with the clinical application. To ensure that the bladder was empty and to see whether elimination of a previous dose had ceased, a specimen of urine was collected from each patient before injection of N.A.B. Supplied with three 1 oz. bottles, patients were told to bring back on the following day a small quantity of the first three consecutive voidings. 1330 tests were performed in the investigation of 397 injections, and a qualitative scale was used to express the results. Positive results were obtained within an hour, and excretion could easily be followed up for 24 hours, or longer. The reaction was usually markedly positive from two to six hours after 0·45 or 0·6 g. N.A.B. Injection of 0·3 g. yielded results slightly less intense.

After an account of a series of cases tested Mr. Lloyd said it soon became apparent that there was a close association between inefficient urinary elimination of N.A.B. and toxic effects in the patient. It had been found in rats that the toxicity of organic arsenical compounds of the trivalent and pentavalent groups was inversely proportional to the rate of excretion in urine and fæces. In man delayed jaundice following injection of organic arsenical compounds was well known as a late toxic effect, and it seemed that the power of the liver to deal with these substances grew less as treatment progressed. During these investigations five cases of salvarsan jaundice and six of exfoliative dermatitis were tested and in none of them could any elimination of N.A.B. be detected. Severe toxic jaundice occurred in five cases, and in none of them had elimination been consistently good with the Abelin test. Among 36 cases in which excretion was known to be unsatisfactory, toxic effects were noted in 19. The intimate relation between toxic jaundice and indifferent excretion raised the suspicion that at least some cases of salvarsan jaundice were due to the action of the aromatic amino radicle in the salvarsan compounds, rather than to the arsenic itself. Toxic jaundice, and even "acute yellow atrophy" of the liver, had been reported following oral administration of atophan, a compound which did not contain arsenic. Jaundice was an exceptional result of poisoning by inorganic arsenic, and chemical analysis of liver from patients who died from salvarsan jaundice did not show any undue accumulation of arsenic. Animal experiments had demonstrated that the most rapidly excreted arsenical compounds tended to be the least effective, probably because of the brevity of their action.

Discussion.

Dr. **David Watson** thought these contributions were of great importance. This test seemed to be the simplest yet suggested, and he was anxious to put it into operation.

Colonel L. W. **Harrison** suggested that the reason for the delayed excretion of the amino-benzol radicle might be that it had been seized upon by the liver-cells. For years he had protested that one should not speak of arsenical but of arsenobenzol jaundice, underlining the last syllable. This idea was strongly supported by the likeness of these cases in many respects to poisoning by trinitro-toluene and by histological examination of the liver. If this supposition were correct, we might have in the Abelin test a means of rapidly determining the value of any measures to avoid the amino-benzol group being taken up by the liver-cells. He had tried previous administration of glucose for this purpose; patients so treated might show by the Abelin test a more rapid excretion than did others.

Dr. H. C. **Semon** did not remember to have seen toxic jaundice or exfoliative dermatitis following the use of salvarsan; but there were other symptoms of arsenical absorption, such as neuritis and changes in the skin, following long-continued administration of the drug by the mouth.

Major E. T. **Burke** said it would be an excellent routine in clinics that, even in cases in which the kidneys appeared to be normal to ordinary tests, Aberlin's test should be carried out on every patient after he had received one or two injections, since the renal excretory function might be abnormal only in respect of arsenobenzol. He was much interested in the references to jaundice. He attributed the rarity of jaundice in his practice to two facts: (1) he used stabilarsan as a routine, and he thought that the glucose, being dissolved in an isotonic solution, acted as a barrier against toxicity; (2) he gave arsenobenzol and bismuth alternately, not concurrently. He would now try the Aberlin test on some recent cases of jaundice which he had seen. He had observed bismuth jaundice in a number of patients who had had no arsenobenzol at all. It would be useful to know what proportion of an intravenous dose of arsenobenzol was therapeutically utilised. Levaditi's experiments seemed to show that arsenobenzol did not exert a direct lethal effect on the organism. These contributions were a step towards establishing the ideal dosage—i.e., one which reduced elimination to a minimum whilst retaining the maximal therapeutic effect.

Dr. H. M. **Hanschell** spoke of a case six years ago in which a man was admitted to hospital diagnosed as having a granular kidney, and treated with a dose of 0·3 g. N.A.B. because of a positive Wassermann. Two days after the injection he died, apparently because of the kidney trouble. Since then, however, Dr. Hanschell had administered stabilarsan to many subjects of renal disease (as shown by albuminuria, casts, &c.) apparently without any ill-effects. He thought, therefore, that the fear of administering arsenobenzol in the presence of renal disease was largely exaggerated. His practice had been to administer stabilarsan and bismuth at the same time, and jaundice had occurred in only one case.

Dr. B. B. **Sharp** asked whether, if Colonel Harrison was right in thinking that glucose protected the liver-cells from the benzol radicle, it would not increase the renal excretion in a previously bad excretor. It would be well to carry out ordinary excretory tests on the kidney in all bad excretors, to see if the kidney was holding back other substances also.

Dr. **David Nabarro** thought that though the test was very valuable, it would be difficult to carry out in children. Children's organs were usually in much better working order than those of their elders, and toxic symptoms following the use of arsenicals were less likely owing to rapid elimination of the drug.

The **President** felt that the test would prove valuable. The chemistry of the body was still largely a closed book. It had been a matter of speculation whether any portion of the arsenobenzol compound passed through the body unchanged. In some cases, it appeared, the test was quite negative, and this suggested either a decomposition so complete that none of the benzol radicles passed into the kidneys, or alternatively a very complete absorption by some of the cells of the body.

Dr. N. L. **Lloyd**, in reply, said that no work had been done by his brother and himself on the effect of giving glucose in improving the voiding of the product by bad excretors. They had tried sodium thiosulphate without success. Three of the five severe cases of jaundice in the clinic had not had any bismuth.

Clinical Cases.

Dr. **Hanschell** showed two patients.

The first was a man who, 20 years ago, acquired a primary chancre. Sixteen years ago his hair began to fall out, and apparently he had had no treatment. He had now received 15 injections of stabilarsan and bismuth. Three weeks after this treatment ceased the man returned with an acutely inflamed tongue. A week later still he developed severe jaundice. The Wassermann reaction was still strongly positive, and the question was whether the condition of the tongue was due to syphilis or was a later arsenical manifestation. This was the first case in 3000 given stabilarsan by him which had developed jaundice after it.

The second patient was a Chinaman, who came from his ship with the diagnosis of acute syphilitic myelitis. He was unable to stand or work. He also had a Hunterian chancre on each eyelid, hard and firm. The knee-jerks were entirely absent; the pupils reacted to both light and accommodation. He had an acute attack of beri-beri. No spirochætes had been found, and antisyphilitic injections had not produced any effect.

Dr. SEMON thought that in the first case the tongue was syphilitic.

JOINT TUBERCULOSIS COUNCIL.

AT a meeting of the Council held on Nov. 16th, Sir HENRY GAUVAIN presiding, the hon. secretary, Dr. ERNEST WARD, gave an account of the present position of the scholarships in Canada and America next year offered by the Sun Life Company. A selection and management committee was appointed as follows: Sir Henry Gauvain (for the Ministry of Health), Prof. Lyle Cummins (to represent the National Association), Dr. Lissant Cox, Dr. G. Jessel, and Dr. Ward. The following memorandum was adopted :—

Improvement of the Tuberculosis Service.

The efficiency of the tuberculosis service varies widely in different districts, but backward areas are being improved by wise stimulation from headquarters. Supervision should not be used so as to hamper individual initiative or impede experimental methods. The chief factor in success is the personality and ability of tuberculosis officers and superintendents of sanatoriums, and to secure this remuneration sufficient to attract good officers is all-important. An indifferent officer fails to obtain the confidence and esteem of the general practitioners on whom so much depends.

It is better to have fewer and better-paid officers with larger areas that a large number of poorly-paid men and women of mediocre capacity. Rural areas of 250,000 population and urban areas of 350,000 can be managed by one whole-time officer, with adequate medical and clerical assistance, and would provide sufficient remuneration. The service should be graded so that those who had acted as assistants might become higher-salaried, whole-time, consultant tuberculosis officers or senior sanatorium superintendents. Superannuation schemes should be generally adopted, or so arranged that an officer does not lose by transference to another district.

The tuberculosis officer and sanatorium superintendent should have at their disposal facilities for diagnosis, such as an X ray outfit, and for special forms of treatment, such as light and artificial pneumothorax. Each tuberculosis officer should have hospital beds. Dispensary and sanatorium officers should be first and foremost clinicians, but should have a public health outlook. Facilities to attend post-graduate courses are of the highest importance. In certain circumstances, where the sanatorium belongs to the authority responsible for the district in which it is situate, it may be advantageous for the medical superintendent of a sanatorium to be responsible for the tuberculosis work in the vicinity of the institution as part of his whole-time duties. It is not intended that this should apply to sanatoriums other than those under direct control of local authorities.

The practitioners' sense of responsibility in the diagnosis, prevention, and treatment of tuberculosis must in no way be impaired, and it is the first duty of dispensary and sanatorium officers to ensure this. One of the most helpful qualifications for these officers is to have been themselves in private practice. Any improvement in the tuberculosis service is closely bound up with the preliminary training of men entering this service, and with the education of medical students and general practitioners in tuberculosis.

A memorandum on the notification of tuberculosis was also adopted. Dr. Lissant Cox undertook to prepare an investigation on the fate of delicate children in tuberculous households. The Research Committee suggested as a further inquiry, the Occurrence of Acute Tuberculosis in Infants and Children under 5 Years of Age. Dr. W. Brand reported that the course in X ray work at the Brompton Hospital was already fully booked; a second course was being arranged after Christmas.

Reviews and Notices of Books.

PRACTICAL LOCAL ANÆSTHESIA.

Its Surgical Technique. Second edition. By ROBERT EMMETT FARR, M.D., F.A.C.S. London: Henry Kimpton. 1930. With 268 engravings and 16 plates. Pp. 611. 42s.

THE first edition of this book appeared nearly seven years ago. Since that time the use of local analgesia has extended considerably and fresh drugs have been brought into play, tutocain, for example, and novocainborate. The value of the book, however, does not depend so much on its being up to date in detail, but on the excellent way in which the broad principles involved in the practice of local anæsthesia are enunciated and explained by the author. His forecast is that "unlike the past, the future will find available individuals who are equipped to offer to patients the greatest merits that local anæsthesia possesses. These surgeons will not only be able to anæsthetise thoroughly the various regions of the body with minimum discomfort to the patient—but will, in addition, realise the full significance of surrounding and protecting the patient with every available artifice essential to its successful use. This concept embodies a large variety of factors. It demands the coöperation of every individual who—in any manner, comes into contact with the patient, the office force, hospital managers, nurses, interns, equipment and, indeed, every factor entering into the patient's environment from the time of his first visit till he is discharged." This statement may appear overloaded, but there is no doubt that attempts at local anæsthesia often meet with only partial success because of the lack of importance attributed to apparently irrelevant accessories. The stage in fact must be perfectly set, and all, not only the chief, actors thoroughly trained in their parts when a conscious patient is being handled. It is from this point of view that the combination of powerful sedatives with local anæsthetics is so important and one may well believe that the success of the latter will be enhanced and their use made more popular by familiarity with such agents as avertin and paraldehyde. The author, however, rightly lays stress on the necessity for the surgeon who wishes to succeed with local anæsthetics being proficient in operating with them on perfectly conscious patients. The method is, in fact, often brought into disrepute by its occasional practice by men not versed in its niceties. As the author writes: "Surgeons of repute would, without doubt, freely admit that none but the most perfectly trained experts should be allowed to administer general anæsthesia, yet without any special training or experience in the use of local anæsthetics they appear to be quite willing to proceed to use them upon their patients." Referring to the early occurrence of pain after operations under local anæsthetics, the author recommends the giving of morphia hypodermically before the patient leaves the table. In wounds which are to heal by granulation, quinine-urea hydrochloride 1 in 600 should be liberally injected as a prophylactic against after pain. Opium is to be used freely during the first 48 hours. All details of technique are fully discussed and illustrated by the numerous diagrams. The author is, of course, an enthusiast for the method of local analgesia, but his support of it is logical, and he does not fail to point out the care and patience which it demands for success.

PRACTICAL SURGERY.

Beiträge zur Practischen Chirurgie. By Dr. ALBERT KRECKE. Two volumes. Munich: J. F. Lehmann. 1929. Pp. 1094. M.12.

THESE two volumes are composed of short essays on subjects suggested by the work the author has carried out in his private clinic during the period 1923–26. There is much sound common sense in his reflections, and it is of interest to read how a practical general surgeon solves the problems coming his way and how his conclusions have been arrived at. Failures are impartially reported with successes. The sections are short and serve to pass an odd hour with profit and entertainment.

ELEMENTS OF HYGIENE AND PUBLIC HEALTH.

Third edition. By J. P. MODI, L.R.C.P. & S., L.F.P.S., Reader of Medical Jurisprudence in the Faculty of Medicine, Lucknow University. London: Butterworth and Co. (India), Ltd. Pp. 645. 10*s*.

THIS is a manual designed for Indian students of public health. It is ambitious in scope and covers the whole field of public health activity, special attention being given to the sanitary problems peculiar to India. In the chapter on ventilation much space is accorded to relatively unimportant details (for example, enumeration of types of inlet), while there is only a brief reference to the work of Leonard Hill (page 93) and no mention of the kata-thermometer. A useful section on the construction of hospitals and schools (page 145) is included, although the size of wards suggested (viz., 40, 32, and 24 beds) does not conform to modern ideals of hospital administration. The chapter on meteorology and climatology contains no reference to ultra-violet rays. Evidence of faulty proof-reading is furnished on page 228, where hydrogen peroxide is described as destroying the water-soluble B-vitamin, thus depriving milk of its *antiscorbutic* properties. In the description of the modes of infection the important method of droplet spread is omitted, and the discredited view that foul air plays a part in the transmission of dysentery and diarrhœa is included. Damp soil is held to predispose to tuberculosis, diphtheria, measles, and other diseases. Noguchi's leptospira is still described as the causative organism in yellow fever, though its association with the disease is not now accepted. The arm-to-arm method of vaccination still appears to enjoy pride of place in India. The hypothesis that putrid meat causes ptomaine poisoning should no longer find a place in a text-book. No reference is made to bacterial agents of food poisoning. The book is marred by a certain crudeness in style and occasional misuse of words.

DISEASES OF THE SCALP.

Pelades et alopècies en aires. By Dr. R. SABOURAUD, Director of the Paris Municipal and St. Louis Hospital Laboratories. Paris: Masson et Cie. 1929. Pp. 378. Fr.80.

THE appearance of this the fifth and last of his series on diseases of the scalp almost coincides with Sabouraud's retirement from hospital routine. The five volumes have occupied his spare time for thirty years, and is not the least of many monuments to his indefatigable diligence and devotion to the scientific progress of dermatology. The subject is arranged in sections which deal consecutively with the microscopic appearances, the bacteriology, the differentiation of analogous conditions of hair loss, heredity and congenital syphilis, causes suspected by patients, associated disorders of the menopause, thyroid dyscrasia, which the author favours as a factor in some cases; and finally, a masterly consideration of the sympathetic and reflex nervous theories first propounded by the author's fellow-countryman, N. Jacquet. The last section is a general summary, and reviews the best of the many treatments that have been advocated. As in the other volumes there are many excellent reproductions of original drawings from microscopic sections and clinical photographs.

There is no cutaneous abnormality so mysterious and dramatic in its manifestations and so frequently discussed as alopecia areata. It has evolved or, rather revolved, in the course of decades through nervous, infective, toxic, reflex, and endocrine-sympathetic phases of conjecture and hypothesis. There is no general agreement to date. A certain "quid ignotum" remains to be discovered—a common factor which will explain the mechanism of production in every case. The subject teems with difficulties, for we are but floundering at the periphery of the endocrine-sympathetic physiology, and are still seeking the instruments of precision which are now available for estimating the functions of most of the other systems and organs of the human body.

The author's modest claim will, we think, be conceded by every reader. "If our conclusions remain dubious, we have at least illuminated the subject to the best of our ability, and we may thereby have facilitated the work of those that shall follow after."

PHARMACOLOGY.

Pharmaceutical Therapeutics, with Pharmacology, Posology, and Toxicology. By ELDIN V. LYNN, Ph.D., Professor of Pharmacology and Chemistry, University of Washington, College of Pharmacy, Seattle. London: McGraw-Hill Publishing Co., Ltd. 1929. Pp. 431. 20*s*.

Prof. Lynn, while not in favour of prescribing by druggists, holds the opinion that the capable pharmacist, in addition to his knowledge of the chemical and physical properties and doses of drugs, must be acquainted with their physiological action and therapeutical uses. This view may be correct, but since it would involve the pharmacist of the future in the strenuous duty of studying anatomy, physiology, pathology, and clinical medicine, he might well prefer to take a medical qualification. The following description of the physiological action of digitalis might well bewilder the reader. "The most prominent result is a powerful persistent stimulation of selected medullary areas, including the vagus, the vomiting center, the heat regulation, the respiration, and the reflexes." The author says in the preface that he has freely consulted numerous treatises on pharmacology, therapeutics, and toxicology. On the whole, he has given a good account of the action and uses of drugs, but it is difficult to see what advantage the book presents to the student of pharmacy over similar works intended primarily for physicians.

Theoretische und Klinische Pharmakologie. Third edition. By H. V. HOESSLIN, Prof. Dr. med., und FRANZ MÜLLER, a.o. Prof. Dr. nat. et med. Leipzig: Georg Thieme. 1929. Pp. 231. M.8.60.

THIS book was published originally in 1921 by Prof. Müller as a companion volume to his text-book for dental students, and while based on the well-known work of Meyer and Gottlieb, was intended to give a succinct account rather than an elaborate discussion of experimental and clinical pharmacology. That it appealed to the German student is indicated by the fact that in 1924 a second edition appeared under the joint authorship of Profs. Hoesslin and Müller, the collaboration of a clinician resulting in a broader discussion of clinical subjects. The general plan is that followed by most modern text-books of pharmacology and therapeutics, though the introductory chapter deals in somewhat greater detail than is usual with the subjects of prescribing, dosage, and the preparations of drugs. There is a short account of general pharmacology, but the bulk of the book deals with special pharmacology, the drugs being classified according to the system on which they exert their main action. By adopting the didactic manner and avoiding discussion, the authors have succeeded in packing more information regarding the action and uses of drugs into its pages than appears in most other works of a similar size. The third edition has brought the book into line with the advances in pharmacology during the past four years, and deals with many of the drugs recently introduced into medical practice. It can be recommended to the busy practitioner as a handy manual of reference, and to the student as a companion to his lectures.

The "Allenburys"
"Perfected"
Cod-Liver Oil

Cod-Liver Oil is the richest available *natural* source of the fat soluble growth-promoting and anti-infective vitamin A and the antirachitic vitamin D.

The "Allenburys" "Perfected" Cod-Liver Oil is examined *biologically* and *certified fully active* with regard to *Vitamins A and D* and when examined by the Antimony Trichloride Test gives a colour *equal to 8-9 'Blue Units.'*

In amber bottles for protection against light
at 1/3, 2/6, 4/6 and 8/6

Descriptive literature and a clinical sample will be sent, post free on application.

Allen & Hanburys Ltd., Bethnal Green, London, E.2
Telephone: 3201 Bishopsgate (10 lines) Telegrams: "Greenburys Edo London."
CANADA—Lindsay, Ont. UNITED STATES—41 Maiden Lane, New York City

"Bynol"
'A perfect combination of Malt Extract with Cod-Liver Oil.'—B.M.J.

'Bynol' contains 30% of the 'Allenburys' 'Perfected' Cod-Liver Oil

The 'Allenburys' 'Perfected' Cod-Liver Oil is examined biologically and certified as fully active with regard to Vitamins *A* and *D*.

Examined by the Antimony Trichloride Test it gives a colour equal to **8-9 'Blue Units.'**

The 'Allenburys' Malt Extract renders **'Bynol'** a rich, easily digestible and palatable product.

Issued in wide-mouthed jars.

Clinical trial sample will be sent on request, post free, to members of the Medical profession.

ALLEN & HANBURYS LTD., LONDON
Telephone: 3201 Bishopsgate (10 lines) *Telegrams:* "Greenburys Edo London"
CANADA—Lindsay, Ont. UNITED STATES—41 Maiden Lane, New York City

[*See also pp. 33, 34 & 35*

Reminders and Suggestions

For the Treatment of INFLUENZA, PNEUMONIA, COUGHS, COLDS, BRONCHITIS, etc.

KINECTINE An organic arsenical salt of Quinine indicated in Influenza, Acute Coryza, etc.

Tubes of 10 Tablets: Dose—One three times a day.

CRYOGENINE (Lumière) A particularly safe and reliable analgesic and antipyretic in all febrile conditions. Bronchitis, Pneumonia, Influenza, Pleurisy

Powder and Tablets: Dose—From 0·50 to 2·50 gm. daily as required.

ORARGOL An electrically prepared Gold-Silver Colloid for general antisepsis and effective colloidotherapy.

Ampoules of 5 c.c. and 10 c.c.

By intravenous or intramuscular injection Orargol is capable of aborting serious cases of Influenza and Pneumonia, and exerts an antitoxin-like effect in acute infectious conditions.

Also supplied in special O.R.L. Outfit for Nasal Irrigation in the treatment of Rhinitis, Tonsillitis and Naso-pharyngeal inflammations.

Extremely valuable as a prophylactic against Colds and Influenza.

SYRUP CREOSAL (Dubois) A combination of Guaiacol, Calcium and Phosphoric Acid pleasantly flavoured with Syrup of Orange Flower & Cherry Laurel.

An excellent specific for Coughs—whatever their origin—Bronchitis, Laryngitis, and all Catarrhal Conditions.

SYRUP PERTUSSIS (Gaball) A combination of deodorised Valerianate, expectorants and sedatives, presented in a palatable form with Syrup of Raspberry.

An effective medicament for the Paroxysms of Whooping Cough.

LITERATURE AND SAMPLES ON REQUEST FROM

The Anglo-French Drug Co., Ltd.,
238a, Gray's Inn Road, LONDON, W.C.1.

THE LANCET.

LONDON: SATURDAY, DECEMBER 7, 1927.

AMENDMENT OF THE LUNACY ACTS.

THE new Mental Treatment Bill which was read a second time in the House of Lords last week was, as may be seen from our Parliamentary correspondent's report, well received. Lord RUSSELL in his opening remarks stated that the Bill had the approval of the chairman of the recent Royal Commission, and we believe that in so far as it provides increased facilities for the treatment of mental disorders the Bill will commend itself to the medical profession. There are certain details to which exception may be taken, but when these are amended the result of its enactment will be to bring the treatment of mental illness much more in line with the general practice of medicine than it has been in the past. Persons suffering from milder forms of mental disorder will, regardless of their social position, be able to obtain treatment without certification and without suffering from any civil disability. The Bill is a short one of 22 clauses. Clauses 1–5 make provision for the treatment of voluntary boarders. Clause 5 provides for treatment without certification of persons temporarily incapable of volition. Clauses 6–10 deal with the duties of local authorities in these matters. Clauses 11–14 provide for a reorganisation of the Board of Control. Clause 16, in amending Section 330 of the principal Act, raises the important question of the protection of medical men signing certificates.

Everyone is agreed that our public mental hospitals should be able to receive voluntary patients. The scandal will at last be ended that persons applying for treatment in these well-equipped hospitals built at public expense should be refused treatment and virtually told to go away and wait until they are bad enough to get certified as insane. Few will quarrel with the proviso that the name of every voluntary patient admitted to a recognised mental hospital or licensed home must be notified to the central authority. The position is, however, very different when voluntary patients are admitted to general hospitals, nursing homes, or under the care of medical men privately. If a person with mental disturbance voluntarily ask for treatment in a hospital or home why should he more than any other invalid have to be notified to the Board of Control? Who, it may be asked, is going to make a distinction between hysteria and mental disorder or to say that this or that person is sufficiently over the border-line to be notified? It is obvious that those in charge of such patients, let alone the patients themselves and their relatives, will object to compulsory notification, with the result that there will be considerable evasion of the law. It should be remembered that Section 315 of the principal Act is not repealed and that anyone who receives persons of unsound mind for profit will be liable to prosecution; indeed if this Bill passes the section may well be much more strictly enforced. Doubtful cases there will always be, and those in charge of them, perplexed and worried at the possibility of prosecution, will prefer to inform the Board of the presence of such patients. If, instead of requiring that all persons with mental disorder who present themselves voluntarily for treatment should be notified, the Bill left this to the discretion of those in charge, the possibility is that all doubtful cases would be reported. This should in itself be a sufficient safeguard. If there were no concealment the evil of illegal detention would be to a very large extent prevented. Whilst it must not be concluded that mere notification would necessarily be a bar to prosecution under Section 315, it is not likely that the Board would initiate proceedings when they had had opportunity of ascertaining all the facts. We trust that obligation to notify all voluntary mental patients will be withdrawn and discretion left to the medical man responsible for the treatment of the patient. We also concur with Lord DAWSON in wishing to drop the word "boarder" altogether. It is most undesirable to draw a distinction between boarder and patient; all are patients and the term "voluntary patient" is sufficiently explicit.

The clauses of the Bill providing temporary treatment for persons unable to exercise volition without certification will prove a great boon to many. The acute puerperal case, many post-febrile confusional cases, a large proportion of alcoholic and toxic insanity will be treated to recovery without formal certification. The procedure recognises recommendations by two medical practitioners, one of whom must either be the usual medical attendant of the patient or a practitioner appointed for the purpose, either by the Board or by the local authority. This creation of a specialist class, although in some respects open to exception, may prove desirable on the balance; it will make the position of practitioners generally much easier if in difficult cases they can call to their assistance someone whose knowledge and experience have official recognition. It is most satisfactory that the Minister of Health has had the courage to depart from the recommendations of the Royal Commission in dispensing with the application to a judicial authority in respect of these cases. How patent it is to everyone with clinical experience that the recommendations—reluctantly proposed by the Commission—requiring an application to a justice of the peace before securing temporary treatment, would defeat the end in view. These patients are not being detained against their will, they are confused and indifferent, and their relatives would certainly not apply to a magistrate unless compelled to do so; serious delay would result and the procedure would resemble so closely that adopted for the certification as of unsound mind that the provision would be hardly worth while. In the House of Lords debate Lord BRENTFORD seemed to suggest that a judicial inquiry was desirable, and the Lunacy Reform Association will press for it. We are of the opinion that the intervention of a magistrate is neither a protection to the patient nor to the medical man who signs recommendations or certificates; it generally means delay, and the protection afforded is illusory. Neither the Royal Commission (nor, we believe, the Departmental Committee which preceded it) was able to find a single case of any person improperly detained; it is surely clear that the public has no cause for disquietude.

The proposed reorganisation of the Board of Control does not greatly affect medical men generally, but

Clause 16 which is designed to give greater protection to medical men signing recommendations and certificates is of great importance. Practitioners are now so unwilling to sign certificates that there is often serious difficulty in securing treatment for insane persons. The actual effect of the new clause is difficult to forecast; we must confess that we do not see a great deal of difference between it and the sections of the previous Acts which it replaces. It is perhaps more emphatic, but it does not appear expressly to say that on the person who wishes to bring an action lies the onus of proving that the medical man "has acted in bad faith or without reasonable care." We have never asked for the recommendations or certificates of medical men to be entirely privileged—privilege would necessitate a judicial inquiry under conditions inimical to the treatment of mental illness; it is clear, nevertheless, that they should not be exposed to the expense and annoyance of proving their good faith and care in the discharge of an unwelcome public duty. The present law does not effectively prevent this, and the new clause must be so drafted as to carry out the manifest intention of the legislature. It is a fact, we believe, that generally in proceedings involving an allegation of negligence—for instance in a case arising out of a collision between two motorists—a much more emphatic proof of carelessness is insisted upon in charges of criminal negligence than in civil actions for damages. It might be possible to insert in the Bill a proviso that no certifying practitioner be held liable in damages except upon clear proof of such degree of negligence as would justify conviction upon a criminal charge.

◆

OPERATION FOR DETACHMENT OF THE RETINA.

THERE are few ophthalmic surgeons who cannot count on the fingers of one hand the cases of "cure" of detached retina within their own personal experience. Yet there are two facts that prevent us from giving up every case that we see as entirely hopeless. One is that there is not the slightest doubt that sometimes, after a shorter or longer interval and with or without treatment, a reattachment does take place, it may be with some restoration of function, and that in many cases where this does not occur extension of the detachment is arrested, and a certain amount of useful vision retained even for a considerable period. The second fact is that when a detachment occurs the detached portion does not at once necessarily lose its function and become dead like the superficial layer of skin over a blister. The detached layer is not in fact the complete retina, but only the part corresponding to the anterior part of the primary optic vesicle. After invagination has taken place there is always a potential space between the anterior and the posterior layer, the latter developing into the pigmented epithelium and always remaining attached to the choroid by which it is nourished. True, the rods and cones which go with the anterior layer are also normally nourished by the choroidal vessels, but when a detachment occurs they seem to be able to derive sufficient nourishment to maintain life for a time, either by lymph from the retinal capillaries whose branches penetrate from within as far as the external molecular layer (but not as far as the nuclei of the rods and cones) or from the choroidal vessels through the intervening layer of fluid. Exactly how this happens has never been adequately investigated, but there is no doubt that it does happen. As H. L. EASON puts it, "For some long period after a detachment the nutrition of the retina remains quite unimpaired and vision is recovered immediately contact with the pigment layer is restored." At any rate this occurs in some cases. Illustrations of these two facts will be found in the discussion which took place in the Ophthalmological Society at its congress of 1915 and the findings of the committee appointed to report on the subject.[1] The latter deals with 85 cases of "cure" in the sense that the retina had gone back into position and stayed there for six months. Now since according to all our past experience the complete reattachment or permanent cure of a detached retina must be considered as exceptional, it is important to classify the cases according to their different causes with a view of determining whether some are more hopeful than others.

Roughly and according to different estimates, from one to two-thirds of the cases are associated with myopia, but it is remarkable that cases of high myopia, higher than 10 or 12 dioptres, are not more liable to detachment than cases of moderate myopia below 10 dioptres. The first classification therefore may be made between myopic and non-myopic cases. The latter may be classified into (1) those associated with a new growth; (2) albuminuric cases which may be subdivided into those associated with pregnancy and those not so associated; (3) those associated with cyclitis or choroiditis; (4) traumatic cases; (5) those in which no definite association can be discovered. Of these the two classes in which the prognosis is not so bad as the average are first the cases of albuminuric retinitis of pregnancy and secondly simple traumatic cases due to an effusion of blood or lymph into the inter-retinal space. Cases of detachment may be classified in what is perhaps a more fundamental way into those which depend on a push from behind and those which depend on a pull from in front. Some authorities in the past have attributed all or almost all detachments to exudation from the choroidal vessels into the inter-retinal space and an osmotic action between that and the vitreous chamber (Rachlmann's diffusion theory). Others have attributed all or nearly all cases to the formation of bands in the vitreous attached to the inner surface of the retina pulling on it and in some cases causing holes in it (Leber-Nordenson theory). Since in some cases the first of these two theories has been proved to be correct and in other cases the second, the truth would appear to lie not between the two theories but to embrace them both, with the proviso that neither must be regarded as applying to *all* cases. Another classification which by some is regarded as of fundamental importance is into those cases in which there is a hole or holes in the retina and those in which there is none. If there is a hole connecting the inter-retinal space with the vitreous chamber and the vitreous is fluid (as it generally is in these cases) it is obvious that any treatment by rest or by puncture which may result in a temporary emptying of the inter-retinal space and reapplication of the retina proper to its pigmentary layer can be of no permanent benefit. Sir WILLIAM LISTER has demonstrated this point with great clearness.[2] On the other hand, it is supposed by some that nearly all cases of detachment are associated with a hole which, however, is often so far forward in the region of the equator that it may be very difficult to detect with the ophthalmoscope.

As to treatment, we must first of all exclude those cases in which the detachment is merely a symptom of an underlying tumour, cases in which no treatment but excision is indicated, as well as cases of complete funnel-shaped detachment in which any treatment is obviously futile. Setting these aside the different methods which have been adopted in the endeavour to find a cure for the condition may be divided into non-operative and operative. The former include rest in bed for some weeks with or without such measures as pilocarpine injections to secure free diaphoresis. Of the latter simple evacuation of the fluid by scleral puncture is the simplest, but the use of the cautery to secure inflammatory adhesion at the site of the puncture is also widely practised. Multiple incisions into the vitreous chamber division of the vitreous bands and in certain cases injection of sterilised calf's vitreous into the chamber are the principles of Deutschmann's operations (1895) by which he claimed a large proportion of successes—lacking endorsement, it is true, from any other operator. Iodine, which was at one time injected subconjunctively, has been revived in the form of subcutaneous injection designed to promote absorption of the effused fluid (RICHARD KERRY of Montreal[3]). The subconjunctival injection of a solution of salt or other fluids calculated to produce counter-irritation is a procedure that can do no harm and is frequently practised. At the recent International Congress at Amsterdam Dr. J. GONIN, of Lausanne, showed paintings of patients treated by a new method designed to close up the hole in the detachment by means of the thermocautery, the results being said to be remarkable. In the report of the Ophthalmological Society of 1916 already referred to, 44 of the 85 cases of cure followed some form of operation, usually scleral puncture, in 41 no operation was done, and in 24 the reposition of the retina took place spontaneously in the absence of any treatment or after treatment had been tried and proved unsuccessful. It is noteworthy that in none of the successful operation cases is there any note of the presence of retinal holes, but in three cases of spontaneous cure holes were noted. With regard to all operative procedures except, perhaps, simple puncture, we have to take into account the fact emphasised by ERNEST THOMSON[4] that in a certain proportion of cases they have actually done harm, as well as the fact that statistical evidence shows that up till 1910 the proportion of cures claimed for non-operative treatment was nearly as great as that for operative. Writing in 1910, THOMSON found that taking the average of the claims of cures by various operative methods he could not put it at higher than 10 per cent., whereas the claims of other writers who adopted solely non-operative methods averaged a proportion of cures of 7 per cent.

[2] Brit. Jour. Oph., January, 1924, p. 1.

Since these percentages are derived from more or less selected cases which different writers have chosen to illustrate the results of the various lines of treatment advocated by them, it is safe to surmise that the actual percentage of cure in all cases is very much lower, and seeing that, so far as is known, the prognosis of operative treatment has not materially improved since THOMSON'S estimate was made in 1910 the particular line of treatment chosen must be left to individual judgment. At the present time the balance of benefit can hardly be said to be decidedly in favour of operative treatment. The most hopeful line of advance in the future would seem to be an increasing knowledge of the pathology of detachment and especially as to the causation and significance of holes.

SOME EFFECTS OF MUSCULAR EXERCISE.

THE physical consequences of heavy exertion have not been worked out at all fully, but modern methods of investigation are steadily supplying us with facts on this subject which are of practical importance in clinical medicine. It has long been known, for instance, that muscular exercise increases the pulse-rate and is followed by a fall in the blood pressure, and radiology now enables us to say that it decreases the size of the heart. While most observers agree about this decrease, they are by no means unanimous when saying at what point it begins. Probably, however, it is present during the muscular effort itself; this is at any rate the view of F. DEUTSCH,[5] who studied Olympic athletes in 1928, and in some 90 per cent. of them found a diminution in the diameter of the heart immediately after maximal physical exertion. The decrease of volume may last a considerable time; after prolonged effort, such as the marathon race, it may persist for 24 hours. The degree of exertion, says DEUTSCH, is reflected not so much in the extent of the decrease as in the time it lasts. Thus the sprinter and the marathon runner show similar diminution in cardiac volume, but the former gets over it relatively quickly. P. P. GOTTHARDT,[6] in a report of nearly 1000 radiographic examinations of the hearts of athletes, agrees in finding no relationship between the reduction in the size of the heart and the kind of exercise undertaken. While it is difficult to say what is a large heart or a small one for a given individual, he came to the conclusion that the relatively large hearts lessened in volume more than the relatively small ones. In his long series he found no form of athletics in which an abnormally large heart was the rule. On the contrary, the bulk of his subjects showed heart widths smaller than the average for people who had not undertaken heavy athletics. The only possible exception to this rule were the swimmers, and it was noted that boxers, runners, and oarsmen had especially small hearts. After months or even years of strenuous athletics no cardiac enlargement could be detected beyond what might be expected from natural growth. The average diminution in transverse diameter after exercise appears to be about 1 cm., and it is not very easy to account for it. Since it follows mild as well as severe exertion, it cannot be due to exhaustion; nor is it wholly dependent on changes in pulse-rate or blood pressure. Rather it must be an expression of alteration in the peripheral circulation brought about, DEUTSCH suggests, by oxidative conditions in the tissues themselves—e.g., accumulation of CO_2 or lactic acid, or altered viscosity of the blood—which affect the venous filling of the heart. If, as is likely, the decrease is present during exertion, it cannot be looked on as a state of recovery, but must be recognised as an accommodative response of the healthy cardiac muscle. Possibly a shortening of muscle follows a brief initial stretching which results from increased diastolic filling. In a diseased organ this shortening may fail to take place, and hence permanent dilatation may follow. According to this view, lasting enlargement from extreme exertion would be evidence that the muscle was previously damaged.

Another organ whose reaction to exercise has lately been investigated is the spleen. Prof. JOSEPH BARCROFT, having formerly shown that muscular effort causes remarkable variation in its dimensions, now (with H. FLOREY[7]) brings forward evidence that in the dog a contraction of the spleen persists when exertion is over. In one case, for example, after moderately severe exercise, it contracted to almost half its resting size and remained in this condition for the 20 minutes during which the animal was under observation. This reduction in the volume of the spleen may be looked on as part of a reserve mechanism whereby the active muscles receive as much blood as possible for their all-important work. Barcroft quotes M. S. Pembrey and others as having demonstrated a corresponding constriction of the renal vessels during severe exercise. The existence of such a reaction is of no little practical importance, and it must clearly be taken into account in conditions like the so-called orthostatic albuminuria. It has long been realised, of course, that traces of albumin are commonly to be found in the urine in normal subjects after strenuous muscular exercise. Recent information about this is provided by O. Hug[6] who, in a study of the Swiss marathon runners in 1928, found a greater or lesser degree of albuminuria in every one of them after the race, whereas beforehand none had shown any abnormality in the urine. The quantities of albumin varied between 0·2 and 0·8 parts per 1000, the average being just under 0·4 per 1000, and these are striking figures which may well cause surprise. Even more remarkable, however, were the results of the microscopic examination of the urine. In every case in which sufficient urine could be obtained immediately after the race large numbers of hyaline and granular casts were found, together with a few red blood cells. In almost all the subjects the benzidin test on the urine was positive —an observation which is suggestive, despite the well-known drawbacks to this test when applied to the urine. Two of the runners were still passing casts and red blood cells in the urine when re-examined 8 and 14 days after the race. Such findings point unmistakably to some definite damage to the structure of the kidney as a result of the exertion, but their like has seldom been recorded by other investigators. Hug suggests that an important factor in the 1928 race was the extreme heat of the day, whereby the competitors were overheated and their urinary secretion was excessively reduced. Possibly their renal damage may be largely attributable to the very high acidity of the urine under such circumstances in combination with the vaso-constriction described by Pembrey. Such inquiries might well be pursued further—perhaps with particular reference to functional albuminuria and related problems.

Such questions as these are closely bound up with the interesting phenomenon of the second wind. This is so definite, and happens so quickly, that it has been put down to the activation of a reserve mechanism —possibly a change of blood pressure, of sweat production, or of coronary circulation. K. F. Wenckebach has drawn a striking analogy between the "dead point" (Totenpunkt) occurring just before the onset of second wind, and an attack of angina pectoris— a comparison which his novel theory of this condition supports. It may be, as Gotthardt suggests, that an initial stretching of the heart at the onset of violent exercise is followed at the moment of second wind by the secondary contraction to which we have referred. Stretching and distension of hollow viscera is certainly a more frequent cause of pain than is contraction, and the same may perhaps be true of the blood vessels themselves. As Wenckebach has pointed out, pain is absent during the vaso-constriction brought on, for example, by cold, but comes on with extraordinary intensity—as all will remember— during the succeeding period of vaso-dilatation.

Annotations.

"Ne quid nimis."

ST. BARTHOLOMEW'S HOSPITAL APPEALS.

On Wednesday last, by setting in motion a revolving beacon, the Prince of Wales, the President, inaugurated an appeal for a million sterling for the reconstruction, enlargement, and re-equipment of St. Bartholomew's Hospital. The appeal was made at a gathering in the Great Hall, and it was fittingly made not merely to London or these islands but to the Empire at large. St. Bartholomew's, founded more than 800 years ago, is the mother-hospital of the British realm, and its claim is as undeniable as its needs. The appeal comes appropriately from the heir to the throne, for St. Bartholomew's has always been the especial care of the Crown, and it holds from his ancestors a dozen charters at least.

A round million is a formidable sum of money, but a little consideration shows that the estimate is not extravagant. It is plain that a building largely 200 years old cannot meet the necessities of so elaborate a mechanism as a modern hospital, and it will no doubt surprise many people to learn that the small maternity ward at St. Bartholomew's is housed in an attic, with dormer windows. Anything more unsuitable cannot be imagined, unless it be the necessity, only now obviated, of wheeling patients to and from the operating theatres across an open quadrangle. Many of these disadvantages to patients, medical staff, and nurses are still being endured. Some of them are in course of removal, but they cannot be completely obviated until the success of the appeal enables the Governors to replace archaic conditions by modern ones making for smooth and easy working, the comfort of patients, and the convenience of those who tend them. A good beginning has already been made. The rapid progress of surgery puts heavy demands upon all hospitals, and St. Bartholomew's has found it necessary to build a new surgical block of 250 beds, with five attendant operation theatres, and to enlarge Queen Mary's Nurses Home to accommodate 50 more nurses. All this work is in progress and nearing completion. It will cost £231,000, of which £138,000 has yet to be provided. A great new out-patients' block, its central hall seating 850 people, with all the necessary appurtenances, has already been built. What has been done and is being done is, however, only an instalment—much more "remains behind." The south, west, and east quadrangle blocks have to be replanned and grouped departmentally, the eighteenth-century fronts being retained. Attic floors will be removed and replaced by new ones, and the south quadrangle block will be given a flat roof for air and sun treatment. Children in-patients, who are at present in adult wards, will be placed in a separate department, the maternity and gynæcological unit will be transferred to the present casualty block, and the new out-patients' block will be completed by the erection of orthopædic, massage, and children's out-patients departments on the site of the obsolete anatomical lecture theatre, chemistry and biology schools of the medical college. That college is to be enlarged by new buildings adjoining the Harvey laboratories, which will provide lecture theatres for medicine and surgery, and laboratories with full provision for research for anatomy, biology, and chemistry, departments at present crowded into inconvenient and obsolete quarters. When money is available it is hoped to supply one of the most urgent requirements of the hospital by building a students' residential college in St. Bartholomew's Close, a part of Rahere's original foundation.

But hospitals do not live by buildings and equipment alone ; in teaching and research they play a part which is ever growing. There is no need to insist upon the position long held by "Bart.'s" in this field, but only to say that in research its fame has been won in face of the most serious handicaps. "Endowment of research" is unknown in Smithfield. There is no endowment for any one of the six professorial chairs in the medical college, and there is urgent need for new chairs and readerships in obstetrics, biochemistry, clinical pathology, and bacteriology. It is the ultimate aim of the hospital to establish an institute for research, and to such purposes will be devoted any money which is not absorbed by things more tangible but not more immediate. Meanwhile, the ordinary expenditure of St. Bartholomew's Hospital exceeds its ordinary income by between forty and fifty pounds a day. Here, then, are abundant opportunities for help, not only in the alleviation and cure of disease but in its prevention. To the man in the street the daily work of a great hospital naturally makes the first appeal, but he is beginning to learn that this work is made possible and effective only by labour behind the scenes. The appeal now being made is indirectly for something larger and more momentous even than the modernisation of the world's most historic hospital.

PASTEURISATION AS A MAKESHIFT.

AT a discussion last week in the Comparative Section of the Royal Society of Medicine on improvement in the public milk-supply, Mr. H. W. Steele-Bodger, M.R.C.V.S., contended in a closely reasoned argument that pasteurisation was making milk dangerous instead of safe for consumption. It had been proved, he said, that coliform organisms persisted in pasteurised milk; of 189 samples of pasteurised milk delivered in 15 areas 40 per cent. had been found to exceed the bacterial content allowed by the Ministry of Health, 20 per cent. exceeded it by a large margin. Moreover, the tubercle bacillus was able to survive pasteurisation, though admittedly it was weakened. His own belief was that if the injected guinea-pig were suffered to live for three months instead of six weeks, there would be a much larger proportion of tubercle-positives. The natural bactericidal power of milk appeared to be destroyed at a temperature of 65° C. and efficient sterilisation removed from milk the antiscorbutic vitamin. Pasteurisation carried with it the temptation to submit to the process very dirty milk in the hope that it would thereby be rendered clean; it tackled the problem from the wrong end, glossing over slovenliness in production and supply, and doing nothing to mitigate the grave economic loss caused by the spread of tuberculosis among cattle. If a tithe of the money, thought, and labour spent in treating the ills caused by dirty and diseased milk were spent in preventing these ills and ensuring a quick and clean service of whole milk, the problem would soon be solved. Local authorities were now paying increased attention to the inspection and control of dairies, and Sir George Newman had recently declared that the milk supplied to-day was a different product bacteriologically from that of a few years ago. In 1922 no more than 5 per cent. of producers were supplying milk with less than 10,000 organisms per c.cm., whereas in 1928 nearly 60 per cent. had reached that standard. In the Midlands, especially in Staffordshire, lists were kept of farmers producing good milk, prizes were awarded, and it was a matter of rivalry to occupy a high place on these lists. At contract time farmers who showed lack of enterprise in the production of pure milk lost their jobs, though unfortunately they seemed able to dispose of their inferior milk readily enough in London and elsewhere. If the consumer was determined to get clean raw tubercle-free milk he would get it, but he must realise that for the better article a better price must be paid. He advocated an intensive campaign of public education, for it was not fair that producers should expend large sums on improving their milk if the public did not appreciate what was being done. Lieut.-Colonel E. C. G. Maddock, who followed him, insisted that the actual workers in milk production were keen to do all that was required of them; the type of farm labourer concerned was gradually undergoing a real change for the better. But the grading of milk was most unsatisfactory, as purchasers thought that Grade A was the best milk. If it was agreed to call Grade A the milk of tubercle-free herds which was bottled on the farm the public would then know that buying this grade ensured that the milk was free from the tubercle bacillus. Mr. P. B. Tustin, while agreeing with Mr. Steele-Bodger that no effort should be spared to get milk fresh and in the whole condition, doubted whether the bacterial count gave a clear indication of the condition of the milk. While in Canada, he said, he had a specimen of bottled milk divided into six portions, each of which was sent to a leading bacteriological laboratory with the request that it should be plated at once, notice having been sent beforehand. If his hearers had seen the differences in the reports on the same milk he thought their faith in the accuracy of the test would be shaken. He cited the instance of a cow which had been brought in with a broken leg. After it was rendered unconscious and suspended, pus ran out of the nostrils, and when the carcass was opened up it was found to be riddled with tubercle. Yet that cow bore a tag issued by a qualified veterinarian to the effect that the cow was free from tuberculosis. Experience such as that had caused him to resolve that he would have all the milk for his own use pasteurised while doing everything possible to control production. In Winnipeg, where the quality of milk at one time was very bad, he had seen to it that every supplier of milk had a concrete floor in his stable, with a separate milk house and washroom. Energy was concentrated on the individual workers, and as their standard was raised the milk-supply improved steadily. But milk had to be produced and shipped in large quantities, we were not living in a Utopia, and for the present pasteurisation could not be done without.

OBSCURE FEVERS OF THE TROPICS.

A GREAT deal of work has yet to be done in classifying the short febrile diseases of the Near and Far East. In such a task it is clear that the Royal Army Medical Corps and the Indian Medical Service have exceptional opportunities. An unrivalled clinical field, the necessity for keeping accurate records, and the laboratory facilities now available, have resulted in some definite advances in our knowledge of these tropical fevers of short duration. Such fevers, as we pointed out in a recent annotation (THE LANCET, Sept. 28th, p. 676), may be atypical or abortive attacks of known diseases or due to some agent hitherto unrecognised. In a Report on Short Fevers at Kamptee, Central Province, India,[1] which was compiled with the help of funds from the Director of Medical Services for India, Major R. N. Phease lately described the modern methods of investigating a seasonal outbreak of epidemic fever of unknown origin. As the result of careful inquiry into every possible factor, he showed that what had appeared to be a local fever with special peculiarities was really a mixture of sand-fly and dengue fever. Incidentally, he entirely failed to demonstrate the virus of either disease, and concluded that it is ultramicroscopic—a conclusion in consonance with those of Knowles and Das Gupta in Calcutta, and Young, Richmond, and Brendish at Landikotal. As was briefly reported in our columns at the time, MacArthur, Dudley, and Whittingham,[2] at the International Congress of Military Medicine, read a paper in which they show that there is a clear distinction in the blood picture between phlebotomus or sand-fly fever and dengue on the one hand, and leptospiral infections, such as Weil's disease, on the other. They claim that in an acute fever, provided that the presence of malarial parasites and the spirochæte of relapsing fever has been excluded, a leucopenia with a relative increase of large lymphocytes points to phlebotomus fever or dengue, while a leucocytosis accompanied by an absolute and relative increase of polymorphonuclears suggests the Weil's disease group. This leucopenia lasts for the first three to five days, and is followed by a transient leucocytosis. The lowest point of the leucopenia occurs six to nine hours after the onset of the pyrexia, and is a useful aid to early diagnosis. A useful suggestion for further research into these short, unclassified fevers is made by S. Smith,[3] who considers that a group with some such label as S.P.A. ("short pyrexial attack") should be created for medical record purposes, and sent up for special investigation by the A.D.M.S. At present the only "unclassified" complaint which it is permissible to have in the Army is the well-known "P.U.O.," and if a diagnosis of P.U.O. is made, it entails segregation and the whole paraphernalia of investigation as a suspected enteric. Short fevers of other origins, which cannot be classified, have therefore to be labelled after their most prominent symptoms—e.g., constipation, headache, &c.—and thus the records do not show the real nature of the illness.

[2] Ibid., October, 1929.

SHOULD THE GUARDIANS BE TOLD?

SUPPOSE that the members of a board of guardians become aware that the admissions to a hospital under their control include large numbers of cases of "incomplete abortion." Suppose that they invite their medical superintendent to suggest some means for putting a stop to such a state of affairs. Suppose that they even press him to say what steps he is taking to bring the offenders to justice. What is the medical superintendent to do?

The answer depends, as usual, upon the point of view. The point of view of the guardians may not be fixed or certain. Some may be indifferent to the situation; others may regard it as a scandal to be hushed up; others again may demand the utmost publicity. Of these last some may even expect the medical superintendent to cross-examine the patient with all the rigours of the third degree while policewomen disguised as nurses make notes of her answers. The point of view of the patient is easier to guess. She may not be vividly conscious of criminal guilt but she will not be anxious for advertisement. She has come to the hospital for treatment, not for persecution; her mental and physical well-being will hardly be improved if she is led to look on the hospital ward as a mere corridor to the assize-court. The medical superintendent himself will probably maintain the point of view of his profession. It is his task, he knows, to save life and to restore health, and for this purpose to win confidence. He will have been trained to remember that it is no part of his duty to act as detective or magistrate, though it is equally not his business to shield a professional abortionist. His dilemma is a difficulty which meets the practitioner in private practice, though hospital experience (for instance when a number of cases are admitted from a particular district) may intensify it. It is the ancient embarrassment of reconciling his duty to the patient with his duty to the public. He will instinctively think of the former while the law will instinctively dwell upon the latter. The point of view of the law will be that the doctor, like any other good citizen, must do his utmost to aid the prevention and detection of crime. Judges have hinted that the doctor should urge the patient to make a written statement, especially if she is likely to die. The law is reluctant to lose a valuable piece of evidence in the always difficult task of bringing an abortionist to justice. In the slightly informal atmosphere of a charge to the grand jury, Mr. Justice Avory once spoke of the moral duty of the medical man to communicate with the police even where the patient was in no danger of death. All criminal trials have their own special facts and that was a case where a woman who had died after an illegal operation had confided to a doctor the name of the abortionist. There is no exact statement of the medical practitioner's duty either in the statute book or in any considered utterance of the Court of Criminal Appeal. No doctor has ever been prosecuted for aiding and abetting criminal abortion by neglecting to cross-examine his patients and to communicate the results to the police. If a doctor thinks fit, and has the opportunity, to urge a patient to make a statement for police purposes, the law will be satisfied and professional confidence will not be infringed. If he does not, the law has no obvious means of punishing him. If he makes the effort and fails, he need do no more. If the patient confides to him the name of the abortionist, it by no means follows that she authorises him to pass the statement on, though she may perhaps be the more readily persuaded to give that authority. If she makes no statement at all, the doctor is not compelled to convey mere suspicions to the police. The policeman's primary duty is to catch the criminal; the doctor's primary duty is to attend to his patient.

The position of the medical superintendent facing guardians who conceive that there is some easy short cut through these difficulties is not entirely imaginary. One such officer, hard driven by the members of his board, protested with dignity against the unfairness of expecting him to deal publicly with these matters and was finally driven to say that, unless he had some guarantee against such insistent pressure, he must decline to attend the meeting of the board. The wisdom and firmness of his attitude will be applauded.

MEDICAL PRACTICE BY FOREIGNERS IN GREAT BRITAIN AND IRELAND.

THE proposed International Convention on the Treatment of Foreigners has led the Privy Council to inquire of the General Medical Council what conditions are imposed on foreigners who wish to practise medicine or dentistry in Great Britain or Ireland. A memorandum by the Registrar states in reply that neither the General Medical Council nor the Dental Board has ever been concerned with the nationality of persons applying for registration in the Medical or Dentists Registers. If a practitioner applies who possesses a qualification entitling him to registration, the Council would register him. It may be that the applicant does not desire to come to this country but seeks registration in order that he may be able to obtain registration in British Dominions and Possessions in which registration, or eligibility for registration, in Great Britain and Ireland is an essential requirement. If the applicant desires to reside and practise in this country, it is assumed that the prescribed requirements in regard to the residence of aliens in this country have been complied with, and the Council makes no inquiries in regard to this. The fact that an applicant for registration possessed a recognised diploma would not, so far as the Council and Dental Board are concerned, be held to override any regulations which might be in force relating to the admission of aliens to this country. With regard to changes of name in the Medical and Dentists Registers, however, in the case of persons who are not British subjects applications are not acceded to unless a deed poll is supplied which has been enrolled in the Supreme Court. If this is done it is assumed that the change has official sanction and the application is usually acceded to. The memorandum goes on to point out that unregistered persons are not prohibited from practising medicine in this country though they are under certain disabilities; they cannot, for instance, hold any public medical appointment, they cannot give any valid certificate required under any Act of Parliament, and they cannot obtain dangerous drugs, or assume any title implying registration as legally qualified practitioners. Apart from this they have entire freedom of practice. Moreover, persons who are not British subjects and who have obtained from a foreign university a degree of doctor in medicine, and are entitled to practise in their own country, may act as resident physician or medical officer of any hospital established exclusively for the relief of foreigners in sickness, provided they are not engaged in medical practice except *in this way*. *This is the position in* regard to medicine. Unregistered persons, on the other hand, are entirely prohibited from practising dentistry in this country.

CARBON MONOXIDE POISONING.

A NUMBER of readers must have been shocked when they saw the account of a recent inquest on two men who had died in the back of a saloon motor-car which was stuck in a water-splash. It was obvious to anyone familiar with carbon monoxide poisoning that the men had met their death from inhaling exhaust fumes, yet the coroner's jury brought in a verdict of death from misadventure—exposure to the elements. Two doctors attended the post-mortem examination and one of them—who was not well received by the coroner—very properly pointed out the peculiar pinkness of the blood which is so characteristic in victims of monoxide poisoning. The opinion of the other doctor, however, prevailed and the coroner and the jury were satisfied that two ordinary healthy men who had drunk no more than a pint or two of beer could meet their death seated in a closed saloon, with windows shut, through sitting for about a quarter of an hour with their feet wet. This verdict involved for the unfortunate driver of the car a committal for being drunk in charge of a motor vehicle. Owing apparently to the fact that the windows beside him were open he escaped with his life, after a period of severe poisoning which the police, not unnaturally perhaps, interpreted as alcoholic intoxication. Happily Prof. J. S. Haldane and Dr. Leonard Hill were among the readers of the report of the inquest and immediately realised that a serious miscarriage of justice was likely to arise. They offered themselves as witnesses for the defence and the case against the driver was dismissed.

It is obvious that the signs and dangers of carbon monoxide poisoning are by no means fully appreciated even by the medical profession and still less by the public. There was considerable discussion at another recent inquest (the *Times*, Nov. 28th) about the cause of the death of two people found in a bathroom in Carshalton. The strong evidence of Dr. Roche Lynch, however, was able in this case to convince the court that carbon monoxide must have been the cause. Dr. Hill wrote to the *Times* on the following day drawing attention once more to the risks of running an engine in a closed garage and in tunnels. The events in the case of the saloon trapped in the splash were very similar to those which occur when an engine *is run in a garage*. The outlet of the exhaust was under water; the driver raced his engine in the effort to drive the car out, and either a leak in the exhaust and silencer let carbon monoxide through into the body of the vehicle or the gas bubbled vertically up from the end of the pipe. The fact that the men had taken beer intensified the action of the gas in producing anoxæmia, but the fumes may well have contained 15 per cent. of monoxide, a concentration which would poison the sober and vigorous. The most recent work on carbon monoxide poisoning appears in the form of two papers by Dr. J. Argyll Campbell[1] from the National Institute for Medical Research, Hampstead. He stresses the striking resemblance between the physiological and pathological effects of carbon monoxide poisoning, of exposure to low oxygen pressure in the air, of hæmolysis, and of hæmorrhage. This supports Haldane's original view that carbon monoxide is not in itself a tissue poison, but acts simply by interfering with the oxygen supply to the tissues. The cause of death is heart failure, and the power to tolerate an atmosphere containing a good deal of the gas depends upon the ability of the vital organs to function under a low tissue oxygen tension. The classical account of the symptoms of oxygen want has been supplied by Prof. Haldane, who describes nausea, vomiting, rapid breathing, periodic respiration, headache, visual disturbance, irrational states, and finally coma and cardiac failure. It is easy to see that such symptoms in a man smelling of alcohol would very naturally be diagnosed as *drunkenness by the police. The irrational states* would add support to their view; those who have read Prof. Haldane's story will remember how he had to be dragged out of his exhaust chamber on the point of collapse, but still protesting vigorously that he was perfectly well.

Another serious question arises when the effects of chronic oxygen starvation are considered. Dr. Campbell's researches have been particularly directed towards chronic poisoning by carbon monoxide, and it is known that people who are continually starved of oxygen may suffer severe and even permanent damage to their circulatory, urinary, and nervous systems without being aware that anything is happening to them. Workers in garages and confined spaces where internal combustion engines are constantly running may be exposed to this risk. More research is needed to give us a definite statement about the chronic form of poisoning, but it cannot be too strongly emphasised or too widely known that death from acute carbon monoxide poisoning may occur *in bathrooms where the geyser has no vent pipe, in* sheds where an engine is running without free access to the air, or even in a closed car on the road if there is any leak in the exhaust pipe under the body; that one part in a thousand parts of air is a deadly mixture, that the poison is insidious and gives no warning whatever, and that the symptoms of partial poisoning strongly resemble those of alcohol. As Dr. Hill suggests in the *Times*, these facts should be taught to all first-aid classes and they should most certainly be familiar to every doctor.

DRAINAGE AFTER CHOLECYSTECTOMY.

AFTER the operation of cholecystectomy, the absence of any inflammatory reaction, a dry field, and the fact that the cystic duct has been ligatured securely, tempt the surgeon to close the abdominal wound completely. The disadvantages of drainage are a possible slight increase in the duration of convalescence, the risk, though *admittedly a slight one*, of a ventral hernia, and the production of an unsightly scar from puckering at the site of drainage. Against these rather trivial considerations have to be set off the risks of a collection of blood in the region of Morrison's pouch, most real in those cases where operation has been carried out in the presence of acute inflammation, and the grave tendency of such collections to become infected. Moreover, quite apart from hæmorrhage, a considerable quantity of bile may drain from the wound; this may be due to inadequate ligature of the cystic duct, but is in many cases, as E. R. Flint has shown, undoubtedly due to the section of accessory hepatic ducts, which are often insignificant and difficult to find or secure, even if their presence is suspected. John A. Wolfer[1] has recently published an interesting experimental study of his results, following cholecystectomy in the dog. His work shows clearly how healing of the ligatured stump of the cystic duct is encouraged by the formation round it of organising exudate. The actual site of ligature separates by aseptic necrosis without any *obliterate* process taking place within the lumen, and therefore, in the absence of organising exudate around the site of ligature, leakage is inevitable. In the dog, at any rate, drainage seems to interfere with the formation of fibrin round the stump, and leakage is more prone to occur where drainage is provided. Wolfer stresses the inadvisability of extensive stripping of the cystic duct, proximal to the site of ligature, since deprivation of its blood-supply is the result, causing further delay in healing. The separation of the ligatured stump occurs about the fifth day, and at this time the strain of coughing or vomiting is sufficient to cause leakage of bile in the absence of a protective cap of fibrin. He points out that, if a drain is used in the ordinary way for approximately 72 hours, there is little chance of fibrin collecting round the stump at the end of this period, and advises that, if a drain is inserted, it should be placed well away from the site of ligature ; in practice this is usually done as a matter of convenience. Most surgeons find the risks of oozing and of possible damage to accessory ducts so serious that drainage after cholecystectomy is likely to remain in vogue. Any leakage of bile, if it occurs, is purely transitory, and if not actually beneficial, is certainly harmless.

THE DRUG TRAFFIC.

A GREAT step forward in the control of the illicit drug traffic was undoubtedly taken when the Treaty of Versailles was made to include ratification of the Hague Conventions of 1912 and 1914, and the League of Nations shouldered the burden of investigating and controlling opium, cocaine, and their derivatives. Nevertheless, the problem remains a very grave one. The world's annual production of opium is about 8000 tons, and it has been estimated that not more than 20 tons are absorbed in medical, scientific, and other legitimate uses. The revolution in China introduced a new difficulty, for the weakened central government is quite unable to put down the revived poppy-growing industry which in 1913 had been completely eradicated. Moreover, a number of States still obtain a large part of their revenue from the sale of these drugs, and they cannot balance their budgets if this source of income is suddenly cut off. The smoking or eating of opium is an ancient habit in many parts of the East and is as difficult to put down as any other time-honoured national custom. Nowadays, moreover, there is a new aspect of the problem—namely, the trade in manufactured products of opium and cocaine, and the gradual invasion of the West by the drug habit. No commodity is easier to smuggle than heroin or cocaine, and the trade is said to be controlled by an international gang with tremendous capital and power.

Two discussions on the subject have taken place in London recently : a conference of the Women's International League on Nov. 14th, and a meeting of the Medico-Legal Society on the 28th. The general opinion of the conference was that nationalisation would prove the only solution of the difficulty. The drug traffic cannot be controlled so long as there is an enormous surplus over and above legitimate needs ; the supply must be cut off at the source. To do this production and manufacture must be taken out of the hands of private individuals and made a government monopoly. This was Viscount Cecil's proposal, and it has also been recommended, as Mr. F. Llewellyn Jones told the members of the Medico-Legal Society, by the League of Nations. The conference promoted by the Advisory Committee to the League, appointed in 1920, resulted in an agreement whereby the eight conferring nations—the British Empire, China, France, India, Japan, the Netherlands, Portugal, and Siam—undertook to suppress entirely the consumption of prepared opium in their territories in 15 years from the time when the poppy-growing countries prevented the exportation of raw opium. They recommended that the importation and sale of opium should be entirely a government monopoly.

Great Britain is as advanced, perhaps, as any other country in the control of these drugs. We have passed the Dangerous Drugs Act, 1920, and thereby put our own house in order. One or two voices were raised at the Medico-Legal Society to protest that this Act had introduced tiresome and vexatious restrictions on the legitimate use of morphia and its derivatives, and that the poor were suffering from inability to obtain morphia for the relief of incurable pain. According to our Paris correspondent[1] this is what is happening in France, where "some chemists actually prefer not to stock morphia at all, in order to avoid the annoyance of inspection." On the whole, however, it seems pretty generally agreed that in this country the honest doctor and the honest chemist can prescribe and dispense these drugs without fear or interference. All restrictions are annoying, but they are accepted cheerfully when they constitute a legitimate safeguard, and those who have heard the histories of drug victims or have seen for themselves the effects of cocaine and heroin on individuals or nations will be ready to welcome any reasonable system of control which will break up the trade. Only eight countries are concerned in the manufacture of these drugs, and the League has hopes of improving the situation by persuading each of them to limit its production to a definite quota of the world's legitimate requirements.

TRAUMATIC OCCLUSION.

SOME of the recent work on traumatic occlusion done by Dr. B. Gottlieb and his school in Vienna was reported to the Odontological Section of the Royal Society of Medicine on Nov. 25th by Dr. E. W. Fish. Gottlieb's experiments, he said, consist primarily in placing metal caps on one or two of the teeth of a dog to increase and modify the masticating strain on them. Sections prepared from the jaws of the animals after the caps had been worn for varying lengths of time showed the effect on the teeth and surrounding tissues. In no case was absorption of the cementum observed but the bone was absorbed on the pressure side of the tooth and deposited along the stretched fibres of the periodontal membrane on the side of traction. When the pressure was excessive the periodontal membrane was destroyed and the tooth came in contact with bone. In such cases the bone was absorbed by being undermined and was not absorbed from the surface which came in contact with the tooth. The destruction of the periodontal membrane in these cases has a bearing, said Dr. Fish, on the association of pyorrhoea with traumatic occlusion.

In the discussion which followed, Mr. F. N. Doubleday suggested that the development of sepsis round the metal caps might have some bearing on the destruction of the periodontal tissues. He thought it important to define the term "traumatic occlusion" and hoped some method would be devised for measuring the forces involved. Mr. J. G. Turner was of opinion that an intermittent pressure such as there is in traumatic occlusion would tend to produce hypertrophy and that absorption would occur only under a constant pressure.

THE DISTRIBUTION OF SICKNESS.

THE study of the causes of invalidity is indeed difficult. First we are faced with the apparent anomaly that the sickness-rates of a community increase as its health improves—because a healthy community contains a large proportion of old people. For years now the general mortality-rate has been falling, and the upward trend of sickness has been correspondingly continuous. How far the decline in the mortality-rate has to go before a decline in the sickness-rate appears no one has yet discovered. Secondly we have to remember that sickness is hard to define ; the attack of lumbago which may withhold a miner from his work at the coal face may not keep a cobbler from his last or a clerk from the office stool. Hence heavy occupations, although possibly otherwise health-giving, tend to experience sickness-rates heavy in proportion to the occupational mortality. Sir Thomas Neill, who lately reminded us of some of these matters in a presidential address to the national congress of industrial assurance approved societies, has pointed out that climate exerts a powerful influence and quoted the case of men employed in building and engineering construction with exposure to weather. According to the *Times* of Nov. 20th, he said that the average duration of a claim in an area in the north of England was considerably longer than that of a claim in the south of England, as was illustrated by the following table:—

---

[1] THE LANCET, Nov. 23rd, p. 1111.

Cause of incapacity.	Excess per cent. of northern area over southern.
Rheumatism	50
Nervous and mental disorders	41
Skin diseases	14
Digestive disorders	21
Respiratory disorders	43
Microbic fevers	38
Accidents	33
All causes	36

Sir Thomas referred also to certain anomalies, as when a clerical worker of a given age in one part of the country has a longer sickness claim than a clerical worker of the same age and sex in another part; and when a woman factory worker in one area suffering from digestive disorder remains longer on the funds than a woman factory worker in another area incapacitated by a similar trouble. Since the industrial population loses every year something between 23 and 24 million weeks' work in England and Wales, study of this enormous economic and social loss is worth while. It is receiving attention from the Industrial Health Research Board, which has already carried out several intensive investigations in cotton-weaving, printing, cotton-spinning, and coal-mining.[1] It has been found that printers suffer most disablement from diseases of the nervous system, and weavers of Lancashire from diseases of the digestive system, which, like other causes of sickness, are particularly high among married weavers. The existence in the total volume of sickness of a substantial proportion of psychoneurotic complaints introduces additional complexity. This group grows when the conditions of life and of work are unfavourable. For example, it was found that coal-miners when working in deep and hot mines experienced more short-time sickness than miners doing similar work in cooler places, but invalidity of long duration was the same for both groups. Miners with similar degrees of slight incapacity not unnaturally have a greater tendency to stay at home when they work under unpleasant conditions. Now that sickness has become so much a financial responsibility and a charge upon industry and the State, efforts must ever be increased to study its causation and its prevention. At present the whole subject bristles with difficulty, and there can be little wonder that the medical sociologist turns from sickness-rates in despair to mortality records, comforting himself with the thought that stone dead knows no fellow.

THE ROCKEFELLER FOUNDATION.

The work of the Rockefeller Foundation is interesting both because it is international and because it is surprisingly polymorphic. The latest report[2] shows progress in many kinds of research. One of the aims is that no worker should be placed in the field until he has had some training in the work to be undertaken, and to this end advice and assistance [illegible] been given to medical schools and to nursing [illegible] public health training institutions all over the [illegible] At the request of governmental authorities [illegible] International Health Division will send representatives to advise on methods of prevention of disease and to assist in the organisation of public health programmes. Financial assistance is usually given only on a small scale so that its withdrawal does not cripple the scheme which it has helped to create. Limitation of activities to the fields described has been found to be necessary, but these are already so wide that a large staff is required to carry on the work involved. Originally, when the Foundation was established in 1913, much attention was devoted to hookworm disease, with incidence surveys and preventive campaigns. Subsequently a similar attack on malaria was undertaken, and in order to further these projects official departments were formed in the countries involved. These departments have since taken over more generalised public health work. More recently the efforts of the Foundation have been directed towards the prevention of yellow fever, and the report includes a description of the methods employed. In North Brazil a representative of the Foundation worked last year in coöperation with the Brazilian Rural Health Service. Antilarval measures were taken at once, and householders were encouraged to realise their responsibility in the prevention of breeding of the yellow fever mosquito, *Aëdes aegypti*. In the absence of a piped water-supply covered water-jars were used, and the number of vessels for each household was reduced to a minimum. Inspections of gutters and drains were instituted. It was believed that by control of the disease in the large coastal cities cases in the less densely populated interior would gradually disappear, a similar plan having been pursued with success in Ecuador, Mexico, and Central America. Unfortunately, however, the transport facilities between the interior towns were such that the disease was continually being carried to non-immune persons, and so persisted. The Foundation is, therefore, to coöperate with the National Department of Public Health of Brazil to extend antilarval work to some of the large interior towns of Northern Brazil. A laboratory was established at São Salvador, and experiments performed which go to show that an attack of Brazilian yellow fever protects against the African virus. It was to study the identity of American and African yellow fever that Hideyo Noguchi went to West Africa during the early months of 1928. He lost his life in the course of work at Accra, on the Gold Coast, while the West African Commission had its headquarters at Lagos. Here experiments were successfully carried out to determine the period of extrinsic incubation—that is to say, the interval between the infecting meal and the time when the aëdes mosquito can transmit the disease by its bite—a period now definitely fixed at 9 to 12 days. Further work undertaken included the determination of the species of mosquito, which are capable of transmitting the disease, and experiments on the protective value of convalescent serum. A laboratory for experimental comparison of the different strains of virus has been established at New York.

ELSEWHERE in this issue it is announced that Lieut.-Colonel W. P. MacArthur has been appointed Consulting Physician to the British Army.

THE sudden death is announced from [illegible] Western Australia, of the Hon. Athelstan [illegible] Henton Saw, Chancellor of the University of Western Australia. Dr. [illegible] who graduated in medicine at [illegible]bridge in [illegible] [illegible]1 years of age.

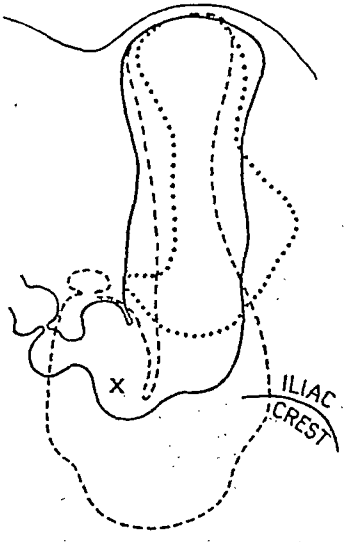
LV.

INTERPRETATION OF RADIOGRAMS OF THE ALIMENTARY TRACT.

PART II.*—THE STOMACH.

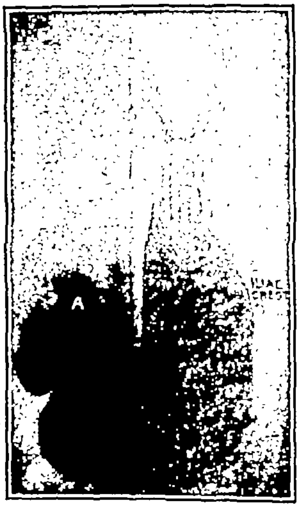
THE length of the stomach varies; moreover, it has no fixed points. It is merely suspended at either end—i.e., (1) where the œsophagus emerges through the diaphragm and (2) where the junction of the first and second parts of the duodenum is attached; this is the point where the two layers of peritoneum that completely surround the stomach and first part of the duodenum separate, forming the hepatoduodenal ligament and leaving the posterior wall bare. Between these two relatively fixed points the stomach hangs and, according to the length of stomach that lies between them, we have widely different forms that have been described as "J," "cow's horn," "fish-hoop" shaped, "gastroptotic," and so forth. Moreover, in the living subject the anatomical position of the attachment of the duodenum is far from being a fixed point. It varies within fairly wide limits in the normal subject and is, moreover, capable of moving an inch or more on palpation. On one occasion I actually manipulated this part of the duodenum across the middle line to the region of the hilus of the left kidney. Little wonder then that we have such very wide variations in the appearance of stomachs which function normally. It does not materially help us to classify them into hypertonic, sthenic, and hypotonic varieties. If we can gain a living conception of a living organ, that is what we need; no one picture can represent the normal.

FIG. 6.



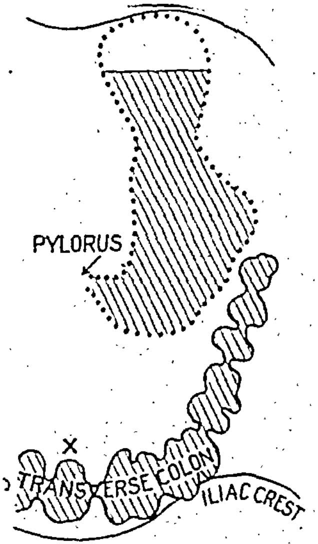
This diagram represents superimposed tracings of three stomachs that were regarded as normal. They are all common types. We are inclined to call the one represented by the continuous line normal, that by the dotted line hypertonic, and that by the broken line as the long type—it is not hypotonic (atonic), since the tone is perfect, nor does it indicate gastroptosis; it is simply a long type of normal stomach.

FIG. 7.



Normal long type of stomach, extending 4 or 5 inches below the crest of the ilium. Note the rugæ showing in the upper part of the stomach. The duodenal cap (A) is rounded, directed upwards, and its attachments have allowed it to drop and adjust itself to the low position of the stomach.

FIG. 8.



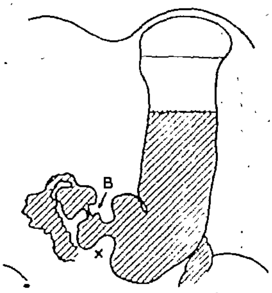
Tracing of a small hypertonic stomach. Not only is the lower border of the stomach high, but the transverse colon is drawn up to the level of the iliac crest. In this figure and the following ones X indicates umbilicus.

The recognition of the possible divergencies that occur within the normal is fundamental (Fig. 6). Inexperienced radiologists, like inexperienced clinicians, will always tend to regard every departure from their conception of the normal as a pathological condition and attribute to it symptoms for which it is in no way responsible. The stomach that extends well below the umbilicus is not necessarily pathological, nor are we justified in speaking of "gastroptosis" on this account. Tall, thin women particularly have this long type of stomach that, in the upright position, extends well below the so-called normal level, corresponding approximately to the umbilicus (4th to 5th L.V.) (Fig. 7). Such stomachs are not necessarily associated with symptoms any more than the short, hypertonic type (Fig. 8) met with in the short, dumpy muscular man that extends only to, say, two inches above the umbilicus. Such variations are not likely to give rise to symptoms except from mechanical causes. Chief among these is the possibility of drag upon the duodenal attachments, a condition that is not always easy to recognise, and is often associated with typical duodenal symptoms, and even with duodenal ulceration. The normal level of the highest part of the duodenum is about the 2nd and 3rd L.V., and if it retains this position when the stomach extends to, say, three or four inches below the umbilicus—that is, well into the pelvis—then we are likely to get drag. But in the case of patients with low stomachs who have no symptoms, we often find that the attachments have allowed the duodenum to come down to perhaps below the level of the crest of the ilium—4th to 5th L.V. Presumably this is why they are free from symptoms. Gastroptosis, of course, exists, especially as a manifestation of Glénard's disease, but the symptoms do not apparently arise from the gastric displacement *per se*. This subject is dealt with in a most complete and masterly way by H. Bedingfield in the *Quarterly Journal of Medicine* for July and October, 1929. The literature surveyed and analysed covers over 600 references.

---

* Part I., The Œsophagus, appeared last week. The Duodenum and Intestines will be dealt with in future issues.

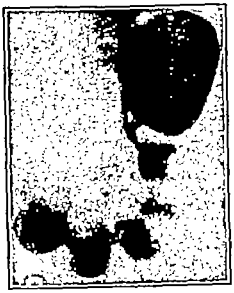
FIG. 9.



Tracing of a film to show hypersecretion. Note that the secretion poured out rises to the top of the heavy opaque food, leaving a non-opaque space between the air space and the contrast meal. On giving Na_2CO_3, the air space will increase by ½ inch or more if the secretion contains abundant free acid. The long pyloric canal (B) suggests the possibility of a pyloric ulcer, a condition in which hypersecretion is often seen. The appearance of hypersecretion is exactly simulated by an opaque meal which is not adequately suspended and rapidly settles down. Apart from hypersecretion and the long pylorus, the stomach is normal.

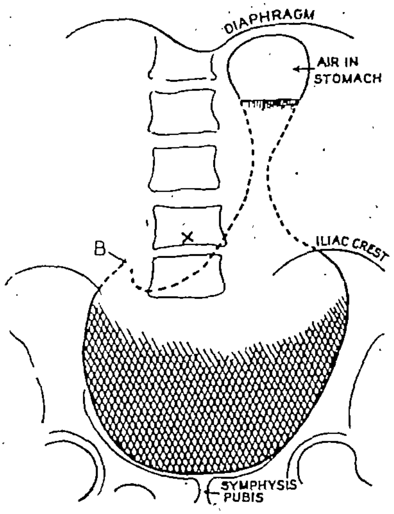
As to function, we have very few guiding points. *Hypersecretion* (Fig. 9) can be recognised by the accumulation of non-opaque fluid above the opaque meal, provided, of course, that the meal has been so made that the barium salt in it has not settled out. By giving an ounce of saturated solution of sodium bicarbonate we can roughly gauge the quantity of free acid in this secretion from the amount of CO_2 evolved. Very active hypersecretion that is apparently unduly acid is often associated with ulceration close to the pylorus. Secretion that is deficient in free acids is not necessarily associated with carcinoma, but, in my experience, is not met with in ulceration, so that this sodium bicarbonate test is of some value. *Peristalsis* is very variable and, apart from extremes, little reliance can be

FIG. 10.



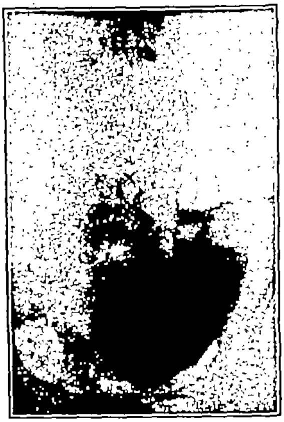
Very abnormally active peristalsis of the stomach, associated with a small ulcer near the pylorus that was eventually detected by palpation methods. Patient recumbent—the fundus is filled with opaque food.

FIG. 11.



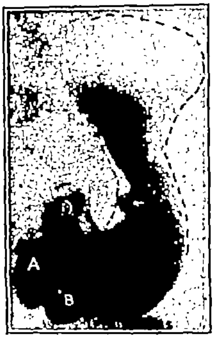
Tracing from a case of extreme old-standing pyloric obstruction. The stomach shows a line of retained fluid or secretion below the air space in the fundus. The lower border shows a crescentic outline that marches with the symphysis and rami of the pubis. No trace of peristalsis is seen. B = pylorus.

FIG. 12.



Long stomach ("gastroptosis"), showing result of air swallowing. Stomach maintains its tone, yet extends almost to the symphysis pubis. The patient is an air swallower, and the air extends down the stomach to the level of the iliac crest. Below this is a layer of fluid —secretion or retained food. The opaque food lies in the lower part and does not fill the pars pylorica. There is no information from the picture as to whether the duodenum has come down or not. Probably it has, or there would have been a large residue of retained food in so marked a case. P indicates the probable position of the pylorus.

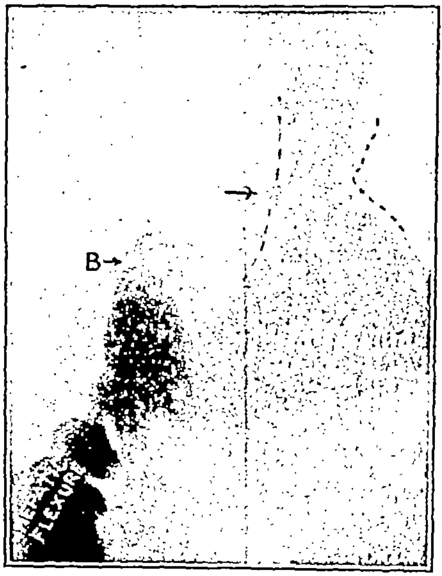
FIG. 13.



Large ulcer on lesser curve. The dotted line indicates the probable outline of the stomach wall, and suggests thickening of the mucous membrane about the ulcer. There is a wave of peristalsis close to the pylorus, and the duodenal cap is well filled. Note how the food is divided up in the duodenum as soon as it has left the "cap." The duodeno-jejunal flexure (D) is also seen. Patient standing.

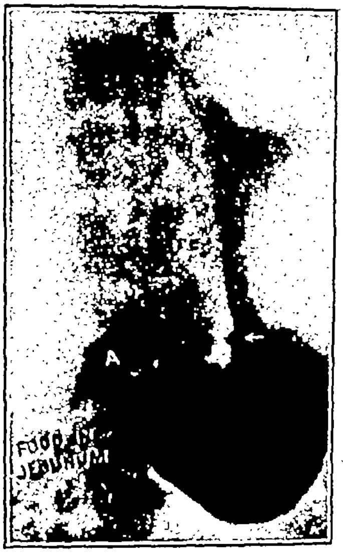
placed upon it as a diagnostic point. Normally the waves succeed each other at the rate of three a minute and are of moderate depth. Occasionally we see the stage of acute obstruction when the peristaltic waves are enormously powerful and the stomach almost writhes; such an appearance is typical of acute obstruction, but it does not tell us whether the obstruction is organic or spasmodic (Fig. 10). The other extreme in peristalsis is the entire absence. In a normal stomach this is not necessarily of pathological significance and is likely to be due to some transitory cause, perhaps a headache or even mere nervousness. Peristalsis is almost completely absent in Fig. 12 (see p. 1211). It is only just indicated by the drawing in of the greater curvature and narrowing towards the lower part.

FIG. 14.



Chronic "penetrating" ulcer near the lesser curvature on the posterior wall. Note the puckering of the mucous membrane. The dotted line indicates the probable outline of the actual wall of the stomach. There is some spasm and consequent hour-glass contraction—probably no organic narrowing. The raggedness of the greater curvature near the narrowing is due to folding of the mucous membrane. The ragged filling defect at the lowest part is due to pressure that has been employed to fill up the crater by manipulation, and the opaque food has not come back into it. Patient lying down and rotated so as to bring the ulcer crater on to the profile of the shadow. B = pylorus.

FIG. 15.



Ulcer on lesser curvature. Note the suggested thickening of the surrounding mucous membrane. The greater curve is ragged, owing partly to the irregularity of the mucosa, but chiefly because it is only partially filled—there is some atony and the food is sagging to the lowest part, leaving the upper half partially filled. The cone shape of the ulcer suggests that the ulcer is healing. The dotted outline indicates the probable outline of the stomach wall. A = duodenum.

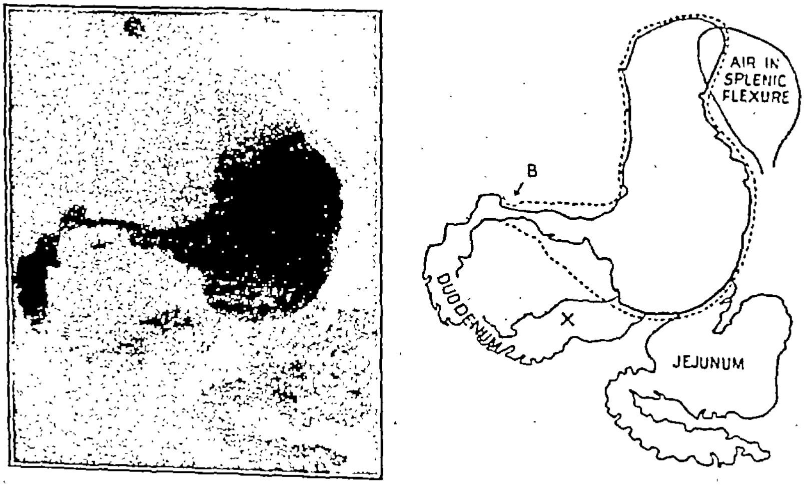
Reverse peristalsis, running from the pylorus towards the fundus, is not very rare, and when met with it always indicates a definite and probably an extensive lesion near the pylorus, usually on the lesser curve.

The *retention of a residue of food* in the stomach always tends to sag the stomach down, and this in turn makes it more difficult for the organ to empty itself. In such cases the tone becomes deficient and the food all sags to the lowest part. There is little or no attempt to maintain the normal tubular form against the action of gravity. The resulting picture is a crescentric shadow of opaque food well below the umbilicus. If on the outline of this shadow we see no evidence of peristaltic waves, or even more important, if we see a series of waves of diminishing intensity followed by a period of rest, we know that we are dealing with a case of definite *pyloric obstruction* (Fig. 11).

Air swallowing with the food is, up to a point, normal, but in certain patients, particularly nervous women, it is excessive, resulting in an accumulation of air in the stomach that is usually brought up with violent and noisy eructation. The patient is quite unconscious of what she is doing and imagines she is generating all this air in the stomach. In such a subject, if we mention that she has air in the stomach and instruct her to bring it up, we see the enlarged air space suddenly diminish, and more often than not, immediately enlarge—she has swallowed more air. Sometimes one can get the patient to distend the stomach with air until the clear area stretches to the level of the umbilicus (Fig. 12). It is an unpleasantly noisy and offensive neurosis that is easily cured by preventing swallowing; one cannot swallow unless the mouth is closed and a cork between the back teeth has brought relief to many.

Air sucking is a different and more complex story that depends on diaphragmatic action chiefly and its treatment in men, as in horses, is as yet unsolved.

FIG. 16.



Growth at the pyloric end of the stomach, probably extending to the duodenum. The dotted outline suggests the true outline of the outside of the stomach wall—the opaque food gives the inner outline only. By palpation we can usually determine the extent of such a growth, and also whether it is adherent. B = probable position of the pylorus.

Rapid emptying of the stomach is noted in association with many conditions, hunger, persistence of purgative action, irritative lesions of any part of the tract—quite often without any obvious cause. But when we note rapid emptying at the beginning of digestion and yet find that there is an appreciable residue of the five-hour meal there are several sites that are at once laid under suspicion—i.e., the gall-bladder, the pylorus, and the appendix.

Delay in emptying, retention of a residue beyond the five-hour interval does not necessarily indicate a lesion at the pylorus or duodenum, or elsewhere for that matter. There are numerous causes that are possible—e.g., headaches, nervousness, gall bladder or appendix trouble, &c., but unless some satisfactory explanation is forthcoming, the observer should confirm the observation and, if it is still present, he should insistently search the pyloric region for the slightest suggestion of the crater of an ulcer.

Gastric Ulcer.

The diagnosis of gastric ulcer is now always made on direct evidence and there should be very few mistakes. The indirect evidence, the formation of an hour-glass contraction due to spasm, although of value in directing our attention and focusing our palpation efforts to show the crater, is of itself not of very first-rate importance, owing to the possibility of such conditions being reflex. The direct evidence consists of the demonstration of the filling of the pocket of the ulcer, and it is surprising what very small ulcers can be demonstrated by a radiologist who is skilled in palpation. It is essential for this purpose that the first mouthful of opaque food to enter the *empty* stomach should be a very thick cream of almost pure barium sulphate. The radiologist should palpate and manipulate this food as it canalises the empty stomach in such a way that he outlines all the folds of the rugæ, pushing the food up and down between them, and eventually allowing it to come right down to the pylorus. It sounds easy, but in practice it is often an extremely difficult manipulation, particularly when the abdominal wall is powerful. Moreover, the radiologist must be extremely careful in the control of the illuminated area, otherwise his hand will be unduly exposed to radiations and eventually he will suffer. It is often necessary to palpate in this way both in the upright and in the supine positions, for it is only in this position that we can satisfactorily fill the cardiac end of the stomach where, fortunately, ulceration is comparatively rare.

The most difficult part of the stomach in which to demonstrate an ulcer crater is the pyloric antrum, and very frequently it requires persistence and the exercise of considerable physical power in order to obtain the necessary information. Occasionally in the presence of florid, flat ulceration near the pylorus it is impossible to demonstrate any abnormality.

When the palpation of the first mouthful has been carried out, more food—about half a pint—is given, and the profile of the shadow searched by turning the patient round. In this way the niche of an ulcer that has been demonstrated by the palpation method can be brought onto the edge of the shadow and a radiographic record of it obtained. It is often extremely difficult, if not impossible, to obtain a satisfactory film to show the pocket of a small ulcer; some of these can only be demonstrated by the palpation method.

The nature of an ulcer that is shown on an X ray film is open to question (Figs. 13, 14, 15). What looks like a large ulcer penetrating right through the wall of the stomach is not necessarily a very deep one, for the mucous membrane around the ulcer appears to be heaped up, forming a large crater. The result is that the pocket gives the appearance of being very much deeper than it actually is. The smallest ulcer that I have seen excised measured only an eighth of an inch and hardly involved the whole thickness of the mucous membrane; yet the pocket that it produced, and which I filled by palpation, must have been ½ or more an inch in diameter, and knowing where to look for it, I could obtain quite a definite projection on the outline of the shadow when the stomach was filled. The only point I know of as a guide to the actual depth of an ulcer is the information one can obtain from palpation. If we can determine that the ulcer base is fixed, we can assume that it has involved the peritoneal coat and become adherent. Sometimes the pocket of the ulcer is so deep that a bubble of air is trapped above the opaque food. Yet even in these cases it does not follow that the ulcer is a true penetrating one—some of these ulcers when excised have shown no suggestion of penetration but merely involvement down to the muscular layer, which was infiltrated and almost cartilaginous. The X ray appearance of penetration must therefore be due to the heaping up of the mucous membrane. The healing of an ulcer can be watched and the manner in which it becomes smaller noted. As it heals, the niche becomes conical—a conical crater very strongly suggests a healing ulcer.

The old-standing ulcer with cicatrisation is now comparatively seldom seen, although these cases were very common in the early days of the opaque meal. An hour-glass contraction is formed and on palpation it is usually possible to find the crater of the ulcer if it is still active. Spasm enters into these contractions to a very large extent, and it is impossible to foretell what degree of narrowing will be found in the operating theatre. It is, however, nearly always far less marked than one would expect from the X ray appearances, since spasm invariably plays a large part.

It is the ulcers near the pylorus on the lesser curvature that are most difficult to diagnose. Delay in emptying of the five-hour meal, intermittent activity of peristalsis, hypersecretion which seems to be abnormally acid, and perhaps a tender point on palpation should always tend to make the radiologist extremely careful and thorough in his detailed examination of the pyloric antrum. Minute ulcers in the pyloric canal are sometimes met with. In addition to one or more of the above signposts, a pyloric canal that appears to be longer than normal will suggest a very careful search for the crater. Unless we can demonstrate the crater, we may suspect the presence of an ulcer but we cannot make a definite diagnosis. Pain on applying pressure to the site of the ulcer is sometimes very definite; quite as often, there is no suggestion that the ulcer is sensitive to pressure, but what determines this is quite unexplained.

Diverticula of the stomach may occur at any point on the lesser curvature. They are rare and the appearances are those of a deep "penetrating" type of ulcer.

New Growths.

The diagnosis of new growths proceeds on the same lines as those employed for the detection of ulcers, but the resulting X ray picture is exactly the reverse—namely, instead of the food-filled pocket produced by an ulcer we have the displacement of the opaque food by the growth, a filling defect (Fig. 10), or a notch. In our palpation of the first mouthful as it canalises the empty stomach, we will probably note deformity of the ordered channels of the rugæ running in the length of the stomach, and displacement of the opaque food. In palpating we may detect resistance due to the growth, and by manipulation we attempt to discover whether or not there is undue fixation—infiltration of the growth into surrounding tissues. A large growth presents no difficulty in diagnosis, but the early growth is often almost, if not quite, impossible to diagnose. A curious and unexplained feature of growths is the fact that the stomach tends to empty rapidly. Note the way in which the second and third parts of the duodenum are shown in Fig. 10: this is due to rapid emptying and consequent overloading. A plaque of growth in the wall, even if it does not cause any filling defect, may cause an interruption of the peristaltic wave. This is not easily detected on the screen, and is best observed by making a series of films in such a way that the suspicious portion is on the profile. A comparison of serial films will clear up the point.

The outline of the normal greater curvature is not always regular—it is quite often "crenated," giving the appearance of the jagged inroads of an extensive growth. Palpation reveals the absence of any tumour, and it may be possible actually to palpate out the cause of the appearance, that is, the oblique direction of the rugæ which pass over the profile irregularly instead of running parallel with it, as usually happens. A growth on the anterior or posterior walls will displace the opaque food and give comparatively transradiant areas in the midst of the opaque food. Manipulation will show up these invasions of the cavity most satisfactorily.

It is always easier to make a positive than a negative diagnosis, and in any case of doubt a further examination after an interval is the safest line to take. The responsibility of the radiologist is a very grave one, and often the clinician will unwittingly press him into expressing an opinion which his observations are not sufficiently definite to justify. There are times, only too many, when it is the obvious duty of the radiologist to hedge and play for time to make more clear the signs on which he has to rely. My own experience is that the doubtful cases nearly always turn out to be negative as regards growth.

In this brief survey many possible lesions are omitted, leather-bottle stomach, papilloma, syphilis, tubercle, &c. They are all, however, so comparatively rare that, together, they do not account for more than a very small percentage of pathological cases.

A. E. BARCLAY, M.D. Camb.,
Lecturer in Radiology, University of Cambridge.

A MEDICAL MASTER OF THE HABERDASHERS' COMPANY.

Dr. Walter Carr, consulting physician to the Royal Free Hospital, is the new Master of the Haberdashers' Company, and a number of medical men attended the Livery dinner held at the Company's Hall on Nov. 28th. Sir John Rose Bradford, President of the Royal College of Physicians, replying to the toast of the "Medical Profession," proposed by Alderman Maurice Jenks, said that it was an especial pleasure to be present because he had known Dr. Carr since they were at school together. The medical profession nowadays occupied a curious position, because although the public were always ready to believe what doctors said about preventing disease, they were by no means ready to accept advice about treatment. For this they preferred unqualified advice—which was strange, because no sensible person would get a picture painted by an artist who had not been trained, or take the opinion of a lawyer who had not been trained, or get a house built by an architect who had not been trained. Fortunately the City companies had always given generously to hospitals and research, and 50 years ago, when it was difficult to get money for such an unfashionable object as scientific investigation, the City companies had given striking examples of benevolence in this cause. Mr. V. Warren Low, vice-president of the Royal College of Surgeons, said that the attitude of his college towards the companies was that of a poor relation towards a wealthy aunt. But few aunts, he thought, had shown such generosity, especially towards research. Replying to the toast of "The Guests," proposed by Mr. G. Woods Woollaston, Norroy King of Arms, Sir Humphry Rolleston, Regius Professor of Physic at Cambridge, spoke of the work of the Haberdashers' Company for education and for the care of the aged. This was an *annus mirabilis* in the City from the medical point of view, for the Haberdashers, the Drapers, and the Pewterers—not to mention the Apothecaries—had all chosen medical Masters. The choice of Dr. Carr was an exceedingly wise one, as he could testify from 30 years of friendship. In replying to the toast of "The Haberdashers' Company," proposed by Mr. R. M. Holland-Martin, Prime Warden of the Fishmongers' Company, Dr. Carr expressed his great pleasure at fulfilling a long cherished desire to entertain his medical friends in the Company's Hall. Among those present were Dr. Robert Hutchison, Dr. H. Morley Fletcher, Mr. Samuel Osborn, Sir Farquhar Buzzard, Mr. Percy Flemming, and Sir Holburt Waring.

SOME OBSERVATIONS ON SCANDINAVIAN SURGERY.

BY T. HOLMES SELLORS, B.M. OXF.,
G. H. HUNT TRAVELLING SCHOLAR, UNIVERSITY OF OXFORD
SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

I.

THESE articles are based upon experiences gained from six months' study in the hospitals of Scandinavia and Central Europe. It was my good fortune to be the first G. H. Hunt Travelling Scholar from the University of Oxford, and I gratefully acknowledge the kindness of the trustees of the scholarship for their approval of my wish to study general surgery, with particular reference to that of the chest, and the use of radium. I also thank the Committee of the Middlesex Hospital for leave of absence during that period. I was much impressed by the internal convenience and management of the Swedish and Danish hospitals, with their small wards and many theatres en bloc, but these have recently been so fully described[1] by Mr. H. S. Souttar that further enlargement is unnecessary.

Although these observations profess to deal with certain special branches of the art, a few general impressions may be interesting to some readers. In Great Britain general anæsthesia is the rule, local the exception. On the continent the reverse obtains—general anæsthesia has a limited application and local a far wider, and is even used for such extensive operations as thoracoplasty and gastrectomy. Gastric operative surgery is almost resolved into gastro-duodenal resections after the methods of Billroth I. and II.; gastro-enterostomy is rare. Prof. Finsterer, of Vienna, is a revelation of exactness and patience in all gastric operations, particularly in those for extensive cancer, all under local anæsthesia. Gastro-enterostomy is never performed in the presence of simple ulceration. Interrupted sutures are universally used, and small needles in a holder preferred to large. The technique of treatment for fractures of long bones varies in almost every clinic, but the underlying principle is the same—viz., extension by callipers or transfixion pins. Prof. Einar Key deals with certain fractures—e.g., spiral of tibia (a frequent result of ski-ing accidents), and both bones of the forearm with inward displacement, by immediate operation. Bone-grafts are always preferred to plates.

From these incidental observations I turn to the

USE OF RADIUM AND X RAYS AT RADIUMHEMMET, STOCKHOLM.

The Radiumhemmet is the centre for the control of radium in Sweden, and at the beginning of this year had two grammes of the element at its disposal, but with the prospect of a larger stock in the near future. There are two other clinics situated a long distance from Stockholm, and these control small supplies, but beyond them no other hospital possesses radium. Patients who are recommended for treatment come under the sole care of the Radiumhemmet, and are treated on the understanding that they will attend for re-examination at regular intervals. State-aid for travelling is given if necessary. An admirable registration and follow-up system is in use, patients being indexed under three separate headings—name, disease, and time for attendance, while dictaphones are freely used for note-taking. The Radiumhemmet only possesses about 40 beds, and as a result the majority of their extensive clinic are treated as out-patients. The Institute is under the control of Prof. Gösta Forssell, with Drs. Berven and Heyman in charge of the general surgical and gynæcological departments respectively. In addition there are assistants who have had at least three to four years' training in radiology before reaching the Radiumhemmet, and there are well-equipped pathological laboratories for investigation and research. The technique and fundamentals of the treatment now in use have been arrived at after considerable experience, dating from about 1910, and have been influenced to some extent by the available quantity of radium. The whole outlook is scientific and is continually changing in an endeavour to find new forms of treatment to replace those that do not give satisfaction over a period of several years. Every patient submitted to the Radiumhemmet comes under its absolute control if suitable, no matter what organ of the body is affected, and the employment of major surgery is at the discretion of the clinic. At the present time radical surgery is frequently used in conjunction with radiology, since the figures for the combined technique are definitely superior to those in which surgery alone, or radiology alone, is employed.

---

[1] THE LANCET, August 3rd, p. 242.

When major surgery is required, the patient is operated on in another hospital in the town by a chosen surgeon, while a doctor from the Radiumhemmet is generally in attendance. It is, however, possible to perform operations at the Radiumhemmet itself, but these are usually confined to electrocoagulation by means of endothermy in conjunction with radiological treatment. The visitor is bound to be impressed by the expert clinical knowledge of malignant disease during all its stages, and there is no attempt to expatiate on the virtues of any particular method. The accuracy of results and observations for publication are definite and the limitations of radium are fully realised in spite of its obvious value in many cases. Biopsy, in the absence of active treatment at the same time, is not favoured, and as a result of their experiences the Radiumhemmet has circularised the medical profession of Sweden, requesting them to forego this examination unless they are treating the condition radically at the same time.

Almost exactly the same principles apply to the Copenhagen Radiumstation in Denmark.

Methods of Use of Radium.—Radium is applied in three ways :—

Intubation.—10 mg. tubes 0·3 mm. lead equivalent screen for buried radium.

Surface Application.—Doses vary; also screen, according to range at which applied.

At a Distance.—Lysholm cannon, with extra 3 mm. screen for deeper radiation over given fields, usually at 5 cm. distance. 20–25 gramme-hours constitutes an erythema dose.

X rays and radium are used so as to avoid marked damage to the general tissues of the body and exposures to them are designed so as to submit as small a volume of the blood stream as possible to the radiation. Reaction is gauged by frequent examination of the blood count, and overdose is shown by a leucopenia, in which the lymphocytes especially are diminished.

Treatment of Special Conditions.

Benign.—Skin and vessel tumours, such as hæmangiomata and warts, are frequently treated by radium in the form of surface applications. Toxic conditions of the thyroid are freely irradiated, starting with very small doses, so as to avoid any exacerbation of symptoms, and with the definite knowledge that surgical intervention will be necessary if the condition does not respond promptly and adequately. A special applicator is used in hypertrophic conditions of the tonsil, which cannot be submitted to operation. Chronic interstitial mastitis is regarded as potentially precarcinomatous and is treated by X rays. Continued observation is deemed essential, but simple removal of the breast is rarely performed for this condition. Leucoplakia is also actively treated on account of its precancerous tendency by superficial endothermy after the area has been cocainised. The coagulated tissue separates off later as a slough, leaving a satisfactory scar. The analgesic effect of X rays on certain common conditions is made use of in many clinics, apart from the Radiumhemmet. Osteo-arthritis of superficial joints may gain considerable relief, while chilblains, whitlows, and furunculosis may improve appreciably.

Malignant Disease.

Oral and Buccal Carcinoma.—From the existing Radiumhemmet figures it is found that there is some variation in the radio-sensitivity of different situations. For example, the lymphosarcoma of the tonsil responds very promptly to radium application, and gives a satisfactory prognosis if there is no glandular involvement. On the other hand, carcinoma of the cheek is comparatively insensitive and, as secondary infection is often present, the main result of radiation is central necrosis with extension of the growth at the periphery. This form, therefore, is more frequently treated by endothermy, sometimes supplemented by radium at a distance. Cancers of the tongue are usually submitted for a start to two cross-fields of radium at a distance with the cannon (20–25 gramme-hours). The affected area is then coagulated between two small plate-electrodes with endothermy, and the periphery intubated with short 10 mg. radium needles inserted vertically for 2 to 4 hours, the tubes roughly being 1 to 1·5 cm. apart. The glandular fields are treated according to their condition. If there are no palpable glands a course of radium at a distance, to total about 20–30 gramme-hours is employed. If on observation there are found to be glands palpable, but not definitely adherent, they are submitted to block dissection by one surgeon, Dr. Hybbinnette, and radium may be buried. The opposite side is treated on the same principle. When the glands are advanced, this is when they are fixed superficially or deeply, radiation is employed, principally with the radium cannon, the dosage being watched very carefully to prevent breaking down of the mass. Carcinoma of the lip is treated on the same lines.

Carcinoma of the Breast.—Formerly the usual treatment of carcinoma of the breast consisted of the radical operation, followed by post-operative courses of X rays, but in recent years preoperative radiation has been employed in addition. Though the actual figures are not yet to hand, there has been a considerable improvement as the result of this and the preoperative radiation is held to be of more value than the post-operative. Preoperative radiation is so timed that the radical and full surgical operation is performed when the tumour is under the maximum effect of the radiation. Microscopically, the tumour cells at this time show, over large areas, degenerative changes with poorly staining nuclei and disintegration. The presence of giant cells also indicates reaction of surrounding tissues against the tumour. Macroscopically, the size of the tumour diminishes, and some cases, which have been classified previously as inoperable, come under the heading of operable cases.

Operable Cases.—The primary tumour is irradiated so as to expose as small a quantity of blood as possible to the radiations over two fields, each receiving 4 to 6 treatments, and each treatment of 1/3 to 1/4 erythema dose (½ Cu. + 1 mm. Al. filter) at a distance of 40 cm. Affected glands in the axilla are treated on similar lines. Some slight redness of the skin will result, and 3 to 4 weeks after the treatment has been concluded the radical operation is performed. The timing of the operation is a matter of considerable importance. The post-operative treatment has been carried out with relatively small doses, the general reaction of the patient being carefully watched. Massive irradiation of the thorax was tried some time ago, but was soon abandoned. Two to four weeks after operation two or three fields are irradiated with 1/4 to 1/6 E.D., with 4 to 6 treatments each (4 mm. Al. filter at 50 cm.). The series of treatments usually covers about a fortnight, and the reaction should scarcely be noticed on the skin. Three months later a second similar series may be given, and a third after yet another three months.

Inoperable Cases.—The tumour with its lymphatic field is treated with similar doses as stated in the preoperative series, and this is carried on until the tumour does not respond by further diminution in size. Then the primary growth is excised with diathermy, making no attempt to form flaps. A large raw area is left, and this is allowed to granulate over, a process which may take some time. In addition, sterilisation by large doses directed against the ovaries is performed, and thyroid is given by mouth. Palliative results over several years have been obtained on these lines, and in a few cases even an apparent cure.

Recurrences.—In cases with recurrences and metastases extensive radiation is not highly valued, since the patient, as a whole, can too easily be damaged. As a result the recurrences are treated either by surface application or by intubation with radium. Rib and bone secondaries respond quite well to this form of treatment, and where possible radium at a distance is often employed. When secondaries occur in the spine, hip, or pelvis the analgesic effect of X rays is valuable, and, in a few cases, relief for some years has resulted.

The lines of treatment, as given above, are preferred to other measures, such as burying radium round the primary tumours and glands, but when sufficient is available the use of radium at a distance has definite possibilities.

Uterine Cancer.—For carcinoma of the cervix operation at the Radiumhemmet has been abandoned, and all cases are submitted to radium treatment. Without anæsthesia, and following routine cystoscopy, an intra-uterine applicator with 3 mm. Pb. screen of about 40 mg. is inserted into the dilated cervix. The vaginal applicators to total about 77 mg. are packed round the cervix, great care being taken to protect the vaginal wall, and so prevent rectovaginal fistulæ. These are left in about 20 hours, and the treatment is repeated in 1 to 3 weeks. Treatment on the same lines is carried out in England with considerable success. This branch is under the control of Dr. Heyman, who combines the rôles of gynæcologist and radiologist.

Skin.—Skin cancers, including rodent ulcers and epitheliomata, give good results when treated by surface application and intubation. The doses are so applied as to produce a good scar. Sarcoma of bone, muscle, and melanomata are treated extensively by radium and X rays, but the results are very disappointing. Carcinoma of the œsophagus and stomach are occasionally treated by cross-fire with X rays, but with no hope of other than temporary palliation. Carcinoma of the rectum is preferably treated by the surgeon, but if X rays are used a preliminary colostomy is deemed to be essential. The burying of radium round the growth demands so wide an exposure to obtain a successful result that practically the standard radical operation has to be performed to ensure its proper application.

In conclusion, I should like to state how much I was impressed with the clinical knowledge of tumours during the course of treatment, and with the balanced judgment of each worker in regard to the prognosis.

EAST HAM ISOLATION HOSPITAL.—The Ministry of Health last week held an inquiry into the application of the East Ham town council to borrow £42,000 for the enlargement of the council's isolation hospital, which is badly overcrowded. Dr. W. Benton, the medical officer of health, stated that to comply with the standard laid down by the Ministry there should be 88 beds only, whereas there are at present 182. It further appeared that some of the nurses sleep in an old army hut, "unbearably hot in summer and very cold in winter," and that an old corrugated iron hut, formerly a store-shed, is used as a dormitory for members of the domestic staff.

THE MEDICAL USES OF RADIUM.

THE Medical Research Council publishes this week a summary of the results of research work carried out at various institutions with the stock of radium salt entrusted by the Government to the Council[1] As the preface points out, from being a doubtful empirical palliative measure for inoperable cases, radium therapy has, during the last eight years, become a curative method of primary value and in some instances is superseding surgery. The Radiology Committee of the Council have allocated the radium at their disposal to the following centres: the Middlesex Hospital; University College Hospital; St. Bartholomew's Hospital; King's College Hospital; St. Peter's Hospital; the Marie Curie Hospital; the General Hospital, Birmingham; the Royal Infirmary, Cardiff; the Royal Infirmary, Aberdeen; and the Irish Radium Committee, Dublin. The committee sound a note of caution in their introduction, for they feel that there is danger lest the general expectation of the public should outrun the real probabilities of radium therapy. "Radium should at present be looked upon," they say, "as an agent for the treatment of localised cancer, and the more limited the region affected the more chance there is of success. Once the disease is generalised the use of radium is mainly palliative."

As in previous years, the reports are conveniently gouped under the headings of regions of the body.

Cancer of the Breast.

The Middlesex Hospital has obtained the best results by using radium at a distance of several centimetres, so that no skin damage has been caused. They suggest the application of greater quantities at still greater distances. For small superficial nodules three or four applications of 10 mg. (gamma rays only) to the square centimetre, half a centimetre away, for four to six hours, usually proved sufficient. Larger nodules were treated from a distance of 2 cm. They have not found that small doses for a long time constitute a good treatment for breast cancer. The usual deep therapy has been a suberythematous dose throughout the area of disease at two or three three-weekly intervals; wide variations in quantity, concentration, distance, and time all gave satisfactory results.

Most of the patients at St. Bartholomew's Hospital were treated by radium needles screened by 0·5 mm. of platinum; a good result was obtained in 45 out of 67 patients so treated. In Dublin[2] needles containing 5–10 mc. radon in 0·4 mm. of platinum or 0·3 mm. of gold were embedded circumferentially around the primary growth and left until 2 mc. per c.cm. of neoplastic tissue had been dissipated. X rays were applied to the glandular regions in divided doses over a week. The early results were satisfactory.

Cancer of the Uterus.

The report of 1927 suggested that better results were being obtained from the Stockholm technique than from any other; this suggestion has been confirmed by the figures for 1928. Of 570 inoperable cases only 130 are alive, but it may be concluded that the radium treatment of operable cases is likely in proper hands to give lasting relief. The difficulty with inoperable cases is that some parts of the disease cannot possibly receive anything like a lethal dose. At St. Bartholomew's Hospital the Brussels technique has been modified by substituting needles for tubes. The external growth is first treated vaginally, and when it has disappeared and all ulceration healed, the abdomen is opened, the liver, pelvic organs, and aortic and iliac glands are examined, and the uterus pulled forward; the needles are inserted, so that only the eye protrudes from the peritoneum, 1–1½ cm. apart, from one sacro-iliac synchondrosis to the other. Four or more are then placed in front of the broad ligaments to attack the obturator glands. The ends of the ligatures are tied together and pushed into the pouch of Douglas. After seven days the abdomen is reopened and the needles removed. The second laparotomy is regrettable but is justified by the necessity for fixing the needles in position and the risk of doing damage by pulling them out blindly.

---

[1] Special Report Series No. 144: Medical Uses of Radium. Summary of Reports from Research Centres for 1928. H.M. Stationery Office. 1929. Pp. 28 and viii. 1*s.*

[2] Report published in Sci. Proc. Roy. Dub. Soc., 1929, xix., 277.

At the Marie Curie Hospital, administered by a group of medical women, a modified Stockholm technique is used. Flat applicators are used instead of cylindrical, as they are thought to give better radiation. Two radium tubes containing 30 mg. radium element and 20 mg. respectively are placed in tandem in the uterine cavity and two or three flat applicators, each containing 25 mg., are put in the vaginal vault. These are left in for 22 hours and the treatment is repeated after a week and again after another two weeks. For cancer of the body 75 mg. are placed within the uterus, and the vaginal applicators are only used at the first two treatments. While this is the routine, every case is considered individually; older patients have smaller doses and the number and position of the vaginal applicators varies with the size of the vagina and the extent of the growth. If the growth shows no response to the three treatments, further application has been found useless and hysterectomy is advised. The only contra-indications were serious pelvic or general infection and advanced cachexia with distant metastases; only 8 out of 274 cases were refused radiotherapy. Even severe anæmia does not forbid radium, but it is well to take every means available for improving the general condition. The report of the Marie Curie Clinic has been published separately[3] and includes a full description of the technique and results, together with a review and discussion of the principal methods in use for radiotherapy of cancer of the uterus.

University College Hospital[4] reports that it is impossible to differentiate between the local sequelæ of radium treatment and the normal ravages of malignant disease. These sequelæ include persistent pyrexia, pyometra, pelvic abscess and peritonitis, fistulation, dissemination of the growth and stenosis, and shortening of the vagina. Workers at the Royal Infirmary, Cardiff, found that fistulæ occurred in 10 per cent. of cases, and do not think that the incidence and circumstances justify attributing any blame to the radiotherapy. They recommend inserting a self-retaining catheter and firm anterior and posterior vaginal packing.

Cancer of the Mouth, Pharynx, Larynx, and Œsophagus.

There is still much difference of opinion as to the best way of treating cervical glands. Block dissection, dissection and insertion of radium needles, and the radium collar all give bad results in many cases. St. Bartholomew's Hospital prefers the insertion of radium needles alone. Birmingham prefers irradiation from a collar containing 70–80 mg. of radium in 5 mg. tubes for 8–24 days, producing a well-marked erythema. Dublin tried intravenous injections of selenide of lead after radiotherapy and regards this as a sound prophylactic measure. Growths in the upper air passages show remarkably different reactions to radium; those of the skin of the nasal vestibule and of the fauces disseminate rapidly and fatally. The technique adopted at St. Bartholomew's Hospital for cancer of the larynx is to expose and fenestrate the thyroid cartilage and to lay needles, screened by 0·5 mm. of platinum, directly on its surface. As the Birmingham report observes, the region is second in difficulty only to the œsophagus; radium is indicated for growths spreading to the opposite cord or running round the larynx. Œsophageal growths are examined, measured and drawn through the œsophagoscope and a piece is taken for microscopy. Radon seeds are introduced by means of a trocar and cannula and placed as far as possible at regular intervals in directions downwards and outwards at a distance of one centimetre. The immediate results have been excellent.

Cancer of the Rectum and Bladder.

St. Bartholomew's Hospital started last year to treat carcinoma of the rectum by needling through the abdomen as a preliminary to excision or to radiation from below. Further, radon seeds have been directly implanted into the growth per rectum. Radon seeds have the advantage that they can be left in situ, but it remains to be seen whether they are as effective as needles. Birmingham irradiates round the growth per rectum and inserts needles into the peri-rectal tissue with trocar and cannula, the average dose being 5400 milligramme-hours. King's College Hospital treated 30 inoperable cases by insertion of radium into the lumen of the bowel. Varying reactions were obtained; in some cases there was radio-necrosis, while in others the effect was inappreciable although the dose was the same.

St. Peter's Hospital treats cancer of the bladder either by inserting 10 mg. platinum needles 0·5 mm. thick into the periphery of the tumour outside and inside the bladder (ulcerative growths) or buried in its base (cauliflower type), or else by burning away as much of the growth as possible by diathermy at open operation and then inserting the needles into the wall around the base of implantation.

Sarcomata and Lympho-sarcomata.

The sarcomata have usually been treated by the insertion of radium, but it is not yet possible to say whether they are best treated by large intensities for a short time or by small intensities for a long time. Reports correlating therapeutic results and histological investigations have been received from the Middlesex Hospital, University College Hospital, Birmingham, Cardiff, Aberdeen,[5] and Dublin. On the whole sarcomata appear to offer a good field for radium therapy. Lympho-sarcomata, though highly sensitive to radium, have a great tendency to become disseminated, and some authorities think the dissemination is accelerated by irradiation. The results are not satisfactory.

Although figures are given in each section of the report, it is obvious that the time for attaching importance to statistical results is not yet. The Committee sound a warning against the use of radium by any medically qualified person irrespective of special training or experience in radiotherapy. The report points out that the superficial application of radium and even its insertion into the body constitute only a very small part of radium therapy, and urges the importance of taking steps to fit more men and women for this highly specialised type of work.

MEDICINE AND THE LAW.

Osteopathic Treatment Censured at Inquest.

TREATMENT given by an osteopath was censured by a coroner's jury at a recent Southend inquest. The deceased, aged 72, had (according to his son's evidence) had a rupture four years ago; he refused the advice of four medical practitioners that a truss would be satisfactory and he followed for eight months the osteopath's prescribed treatment of manipulation, diet, and exercise. As there had not been attendance by a registered medical practitioner his death could not be the subject of a medical certificate. A post-mortem examination was conducted by Sir Bernard Spilsbury in the presence of the coroner and the osteopath. Sir Bernard at the inquest described the body as emaciated, the flesh sunken, and the ribs prominent; internally there was an almost complete absence of fat; acute pleurisy and pneumonia were

IRRADIATED MILK *v.* COD-LIVER OIL FOR RICKETS.

To the Editor of THE LANCET.

SIR,—The interesting communication by Miss K. H. Coward, D.Sc., on the Value of Irradiated Milk compared with Cod-liver Oil as a Source of Vitamin D (THE LANCET, Nov. 23rd, p. 1090), prompts me to comment. While Dr. Coward refrains from drawing any conclusion of direct clinical application from her results, it is clear that two conclusions might reasonably be drawn from her statement by clinicians or others. One conclusion—favourable to irradiated milk—is the possible advantage of adequately irradiated milk over cod-liver oil in the case of very young infants, where, in not a few instances, difficulty is experienced in the administration of even 10 drops of a " good average oil " regarded by her as equivalent in clinical value to a pint of " the weakest sample of irradiated milk." The other conclusion—less favourable to irradiated milk—is that in so far as " weight for weight a good sample of oil contains from 50 to 1000 times as much antirachitic vitamin as current samples of irradiated milk," the practical value of irradiated milk for older children or adults is slight. Dr. Coward herself may not accept this conclusion; in any event it is advisable to point out reasons for its rejection.

For the past nine months I have been investigating the clinical effects of irradiated milk in the treatment of rickets, in order to confirm or refute the remarkable results claimed from its use by German investigators. The results of a first series of investigations (published in your issue of Oct. 5th) confirmed the claims of the German authorities for the therapeutic value of irradiated milk in the treatment of rickets. I had an open mind as to whether any benefit that might accrue from the irradiation could be correctly ascribed to vitamin D, and the facts recorded by Dr. Coward justify my hesitancy. If the foundation of the test is not entirely accurate—in other words, if the present conception of vitamin D is not the whole truth—great caution is necessary in appraising its results. Dr. Coward found that the sample of irradiated milk I sent to her laboratory showed the presence of " antirachitic vitamins " to the extent of 0·1 unit per gramme—the lowest content recorded, but this very feeble vitamin D milk yielded the remarkable clinical results recorded in our paper and is still continuing to do so. In view of the great potency of this milk in rickets, it is a matter of interesting speculation as to what would have resulted from the use of the richest vitamin D milk 20 times stronger.

In our paper these anomalous findings were kept in view and were referred to in the statement " with fuller knowledge time may show that these tests may require modification "—the tests referred to being the line test employed by the Pharmaceutical Society, and the ostelin units per gramme test as described by Jephcott and Bacharach. Dr. Coward's clinical record confirms the view put forward tentatively in our paper.

I am, Sir, yours faithfully,
CHALMERS WATSON, M.D.
Edinburgh, Nov. 29th, 1929.

To the Editor of THE LANCET.

SIR,—I have been somewhat astonished that Dr. Coward's sweeping generalisation on the absence of vitamin D from cow's milk should be accepted without demur. On the findings of an unknown number of tests by a method which is not described, on a series of milk samples of undescribed source, Dr. Coward comes to a conclusion of far-reaching importance. These results are quite opposed to the summary of recent work on vitamin D and milk which lately appeared in the editorial columns of the *Journal of the American Medical Association* (vol. xciii., p. 1380). There Sherman and Striebling's researches are quoted demonstrating that, in a diet otherwise free from vitamin D, from 5–10 per cent. of the calories coming from a whole-milk powder carried sufficient vitamin D for normal growth and calcification. I should be grateful if Dr. Coward can be persuaded to amplify the data of those investigations on which her important conclusion is based.

I am, Sir, yours faithfully,
Bristol, Dec. 2nd, 1929. FRANK BODMAN.

THE CRAFT OF SURGERY.

To the Editor of THE LANCET.

SIR,—Prof. Tonks has called attention to a serious deficiency in the training of our surgeons. In the days of Jonathan Hutchinson and Frederick Treves, when I qualified, we did not lack material or the teaching of diagnosis; text-book " cram " then, as now, was a necessity, marks had to be obtained on the written part of the examinations, and the best memory got the most marks, the craft of surgery in its endless detail was not taught then any more than it is now. Since 1887 I have been, until two years ago, on the surgical staff of county hospitals. I have seen the work of a multitude of house surgeons, and I look back with something like terror at my own early want of knowledge of surgical craft, and the like ignorance of my residents.

Fellows, masters, or bachelors of surgery in their early days are no better craftsmen than the pass man. If we are carpenter, musician, or art student we show manipulative dexterity, not because of our medical training, but in spite of it. How many surgeons within six months of qualifying could give the many directions to cut a special splint in wood or metal? How many men, as Mr. Rocyn Jones inquires, can use a chisel or saw? The use of a needle or thread in the hands of the average young man is a travesty in stitching; the application of pressure forceps guarantees in many cases the necrosis of an area round a blood-vessel.

Young men and women are full of technical knowledge and theory, but a practical knowledge of surgical craft is almost negligible. Prof. Tonks, a demonstrator of anatomy and a well-known artist, tells us that as a F.R.C.S. he was not taught the craft of surgery; he may never have done an operation, although holding the highest qualification. I was in the ranks of surgery, and I had to learn my craft after examiners had finished with me. In all humility I submit that Fellows are in the like position. Most of us owe our position on the staff of county hospitals to the goodwill of a lay committee, not because we are craftsmen. We may learn it by practice but we have no technical training.—I am, Sir, yours faithfully,

Tunbridge Wells, Nov. 28th, 1929. W. B. COSENS.

AVERTIN ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—I should much have liked to have been present at the discussion on avertin anæsthesia which was recently held at the Royal Society of Medicine (THE LANCET, Nov. 9th, p. 978), and to have given my experience of the drug which now runs into hundreds of cases. I have used it in every type of surgical case from operations on the skull and its contents down to amputations, and I shall continue to use it owing to properties which are a genuine delight to both patient and surgeon.

The contra-indications of avertin anæsthesia are few and limited to kidney disease and low blood pressures. The only drawback is that certain patients are noisy, perhaps a little restless, when the effect of the drug is wearing off. Only in exceptional cases can avertin by itself be said to give complete anæsthesia. Its great use is in combination with other drugs, which in themselves are insufficient. Thus an absolutely non-toxic pleasant and totally efficient combination can be obtained, which is the ideal.

In children, avertin is used in combination either with infiltration anæsthesia (½ per cent. novocain in 1/200,000 solution of adrenalin hydrochloride) or with a very minute dose of ether, on an open mask. No preliminary morphia should be given to children under 14 years. In older people, morphia gr. 1/6 is given hypodermically half an hour beforehand. Avertin in adults can be combined with spinal anæsthesia, and this has been the ideal combination for the more difficult abdominal operations such as partial gastrectomy, cholecystectomy, resection of growth of the colon, and so forth. Here the avertin must be given three to five minutes before giving the spinal injection, otherwise the latter relaxes the sphincter ani, and part of the former drug is voided, spoiling the effect of the combination. For other operations in adults its use with infiltration anæsthesia as for children forms an ideal combination for operations on the breast, thyroid, hernia, and so forth.

Avertin (except in cases of kidney trouble or low blood pressure) has the following great advantages:—

(1) It is, in my experience, non-toxic and absolutely harmless.

(2) It is quick in its action; the patients are asleep in from three to five minutes after administration.

(3) In the greater majority of the cases it provides refreshing sleep for several hours after operation.

(4) It has a beneficial psychological action, for it has banished the dread of the anæsthetic mask and the surroundings of the operating theatre. This is a great factor in children.

(5) It can be administered by a nurse, although an anæsthetist should be present.

In conclusion, I emphasise three precautions. The tendency of the jaw to slip backward and produce a degree of cyanosis should be avoided by keeping the head low and on its side. The drug should always be tested with congo red before use. A dose of 0·1 g. per kilo of body-weight should be given.

I am, Sir, yours faithfully,

Bradford, Nov. 29th, 1929. BASIL HUGHES.

THE PURCHASE OF DANGEROUS DRUGS.

To the Editor of THE LANCET.

SIR,—In my innocence I thought that since the Dangerous Drugs Acts came into force the opium-taker could not purchase his dope unless he did so in a surreptitious way. Yesterday a case came under my care which showed me that an opium-fiend can buy just as much as he wants from any chemist who will sell it, provided that it is diluted sufficiently to come outside the Act, and also that the chemist has no need to enter such sale in his poison book. The woman was taken acutely ill with a septic condition, and it was found she had many 6 and 8 oz. bottles labelled "Laudanum, dil. 1 in 8." Her husband, a labourer on less than £3 a week, says she spent 15*s.* to 20*s.* a week on the stuff. But the most terrible part of the business came out later at night. A six-year-old grandchild she was bringing up began screaming for "her drops from grannie,"—did so all night. I inquired of the police if any action could be taken. They thought not. In fact they had in their possession a confession by the woman of her having given opium to an elder child now in a reformatory.

Cannot this evasion, which nullifies all the intentions of the Act, be brought to the notice of the proper authorities?—I am, Sir, yours faithfully,

Scunthorpe, Lincs., Nov. 20th, 1929. W. S. HALL.

CONTRACTILITY OF CAPILLARIES.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 9th (p. 1010) Dr. J. F. Fulton makes a valuable addition to our knowledge by revealing James Black's Description of Contractility of Capillaries (1825). Dr. Fulton mentions that neither Krogh, in the second edition of his monograph, nor Lewis, cites the interesting study by James Black. So far as Krogh's book on capillaries is concerned (2nd edition, p. 2), he distinctly states his work is not a monograph, and that he does not aim at a complete presentation of the literature of the subject. As a worker in the same field, I should certainly agree that the literature of the subject is not completely or even adequately presented by Krogh.

For example, the first published description of direct microscopic observation of the circulation going on in the glomerular arteries and capillaries, and the first published description of direct microscopic observation of the circulation going on in the capillaries, &c., of the liver, are both omitted from the text, and from the bibliography of Krogh's book. This is unfortunate, but as long as p. 2 of Krogh's volume is retained, there is no *one* responsible. On the other hand, if Krogh's volume is looked upon as an exhaustive monograph, then my colleague Leonard Hill, who is the author of the first of these discoveries, and myself, who am the author of the second, had better resign ourselves to the fate of James Black, although one never knows what might turn up in kindly obituary notices.

I am, Sir, yours faithfully,

JAMES M. MCQUEEN.

Halesowen, Worcester, Nov. 27th, 1929.

DIAGNOSIS OF GASTRIC DISEASE.

To the Editor of THE LANCET.

SIR,—Dr. Rowden's letter misrepresents my statement and my views. He bases his remarks on a very condensed version of what I said at the conclusion of a discussion; if he will refer to the fuller, but necessarily abridged, account of my opening remarks at the same discussion (THE LANCET, Nov. 16th, p. 1041) he will see that he might well have saved himself the trouble of writing. During the course of the discussion one speaker described a case of anæmia, anorexia, and fever, which was finally diagnosed at a clinic as one of gastric carcinoma. In my reply I merely pointed out that anæmia, anorexia, and fever were three well-recognised clinical symptoms of gastric carcinoma; it must be obvious to anyone that they are symptoms of the disease in an advanced stage. I agree with Dr. Rowden about the importance of careful study of dyspepsias at or after middle life, but it should also be appreciated that a considerable proportion of all cases of gastric carcinoma are already advanced before symptoms appear or the patients think it necessary to seek medical advice. Finally, there are plenty of functional dyspepsias after the age of 35 which may be recognised and classified clinically, and in which it is quite unnecessary to subject the patient to the trouble and expense of an X ray examination.

I am, Sir, yours faithfully,

London, Nov. 21st, 1929. J. A. RYLE.

G.M.C. ELECTION.

To the Editor of THE LANCET.

SIR,—As an independent candidate, I desire to thank all those practitioners who kindly voted for me in the recent election of Direct Representatives on the General Medical Council. Though not elected, I consider the result (2010) to have been very encouraging.

I am, Sir, yours faithfully,

Dec. 2nd, 1929. ARTHUR HAYDON, M.D., F.R.G.S.

ROYAL MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET.

SIR,—The sum of £13 has been received up to the end of November for Christmas gifts in response to Sir Thomas Barlow's appeal published on Nov. 22nd. The subscriptions have been received from the following: Anonymous (Edinburgh), Dr. H. E.

Bloxsome, Dr. G. M. Bluett, Mr. W. C. Bull, Dr. W. J. Dixon, Mr. H. A. T. Fairbank, Dr. J. Fawcett. Dr. J. C. M. Given, Sir Charles Gordon-Watson, Dr. N. G. Horner, Dr. J. Hudson, Dr. R. G. MacGowan, Dr. J. C. Maddison, Dr. D. D. Malpas, Mr. W. M. Mollison, Mr. W. S. Thacker Neville, Mr. H. T. Nixon, Dr. J. Orr, Sir R. W. Philip, Dr. C. F. J. Smith, Surg.-Lieut. L. D. Spero, Dr. W. B. Tomson, and Dr. J. Walker.

The amount of money required for Christmas gifts is £500, so that further donations are very urgently required, and should be sent to: The Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos-street, W. 1.

I am, Sir, yours faithfully,

E. C. PENNEFATHER,
Secretary.

Dec. 3rd, 1929.

ELECTRICAL TREATMENTS IN ACUTE CONDITIONS.

To the Editor of THE LANCET.

SIR,—I did not see Dr. Bauwen's letter in your issue of Nov. 16th, with its stimulating criticism, until some days after publication, or I would have written sooner to say how entirely I am in agreement with him on the need for "electro-therapeutists expressing their thoughts in recognised technical terms." I have read through the paragraphs in my original article to which he takes exception, and in so far as I have transgressed in not "expressing my thoughts in recognised technical terms," I must cry *peccavi.* As an offender in the matter of rules that I consider should be observed, the only extenuating circumstances that I can plead are that the lecture was addressed to students, and looseness in technical expression tends to creep in when one so well knows that many electrical terms convey little or nothing to them.—I am, Sir, yours faithfully,

C. B. HEALD.

Park-crescent, Portland-place, W., Dec. 3rd, 1929.

A WHITE BLACK-BOARD FOR THE OPERATING THEATRE.

To the Editor of THE LANCET.

SIR,—Every surgeon in a teaching hospital, either just before an operation or even during its performance, must on occasion have wished to draw a diagram—a wish denied his gloved hand by the rule of asepsis. In my own theatre I have met this recurring need for surgical illustration in a simple way, and I can now go at any time to a board hung as a fixture on the wall and draw or write upon it without breaking the aseptic routine of operation. Chalk dust is undesirable, and I use the soft crayons, made on a grease basis, which are sold for children in every stationer's shop. These crayons require a white surface, which was got by painting an ordinary black-board with white enamel paint. The board is convenient to the operating table and in easy view of the students' gallery. The crayons stand, point downwards, in a metal rack like that employed for tubes in the Wassermann test. The required crayon is grasped with long, sterile sponge forceps, which are fenestrated. Six will hold the traditional colours of anatomical diagram. The crayons are best used short—a stub does not break off. Crayon marks can at once be effaced by an attendant with a swab moistened with ether. This, in time, removes a thin film of paint, but so thin that after two years my board remains clean, white, and attractive.

I am, Sir, yours faithfully,

ARNOLD K. HENRY.

Faculty of Medicine, Cairo, Nov. 13th, 1929.

ABERGAVENNY COTTAGE HOSPITAL.—Lady Mary Herbert last week laid the foundation-stone of a new wing which will include a maternity ward. This will be the third enlargement since the hospital was built in 1901; as a dispensary it has existed since 1828.

Obituary.

SIR ARTHUR SLOGGETT, K.C.M.G., K.C.V.O., F.R.C.S. ENG.,

LATE DIRECTOR-GENERAL OF MEDICAL SERVICES.

THE death of Lieut.-General Sir Arthur Sloggett, Director-General of Medical Services in France during the late war, and Chief Commissioner of the Red Cross (briefly announced in our last issue), occurred suddenly on Nov. 27th, just after he had reached his seventy-second birthday.

Arthur Sloggett, the son of the late Inspector-General W. H. Sloggett, of Paignton, by his wife Elizabeth, daughter of Thomas Crossing, J.P., of Stoke Damerel, was born at Stoke Damerel, Devon, and received his education at King's College, later joining the medical school of King's College Hospital. He obtained the qualifications of M.R.C.S.Eng., L.R.C.P. Edin. in 1886, immediately after which he entered the medical branch of the army. From that time forward he was constantly on active service, and as long ago as 1896 became a marked man when, being senior medical officer on the expedition to Dongola, he was mentioned in despatches, promoted to Surgeon Lieut.-Colonel, and received two Egyptian decorations. Two years later he was the senior medical officer of the first brigade of the British division in the Nile Expedition, and at the Battle of Khartoum was shot through the chest, an injury from which he made a remarkable recovery—he is said to have accounted for the fortunate issue by explaining that "his heart was in his boots." Further mentions in despatches, promotions, and decorations followed. In the South African War he was placed in charge of the Imperial Yeomanry Hospital, being later P.M.O. at one of the general hospitals. He played a prominent part in all the operations of that prolonged struggle, was again mentioned in despatches, decorated, and received the C.M.G. In 1903 he was the P.M.O. to the Home and London districts, an appointment which he held for five years, when he became P.M.O. to the Bombay Presidency. In 1911 he was promoted to be Director of Medical Services in India, and received the C.B.

SIR ARTHUR SLOGGETT.

[*Photograph by Elliott and Fry.*

Sloggett had been called home to succeed as Director-General Army Medical Services three months before the war broke out, and in September, 1914, he was appointed Director-General of the British Armies in the Field, as well as Chief Commissioner of the British Red Cross and the Order of St. John. As all know, he discharged his onerous duties with vigour and conscientiousness. In the late Sir William Macpherson's "General History of the Medical Services in the War," which is based on official documents, it is stated that the scheme, whose duality was criticised, worked admirably throughout the war, its success being essentially due to the fact that the regular organisation of the Army Medical Services was no longer subject to the conflicting interests and rivalries of voluntary aid organisations. What really emerged was the fitness of a man of Sloggett's attributes—of his tact, good temper, and energy—

for a difficult post, carrying responsibilities that might easily have become mutually antagonistic.

In June, 1918, Sloggett's term of office ended, and there was considerable difference of opinion as to whether it should be extended in recognition of the way in which he had met his duties. Representations to this effect were made in several quarters but were unavailing, and Sir Arthur Sloggett was succeeded in the ordinary course by Lieut.-General Sir John Goodwin, the present Governor of Queensland. Sloggett made for himself a great name by the way in which he discharged for more than three and a half years his far-reaching commitments, his success being made possible alike by his 30 years of official experience and his innate qualities of sympathy and geniality.

Sir Arthur Sloggett's honours were many. He received the C.M.G. nearly forty years ago, was made C.B. in 1910, was knighted in 1914, and in 1917 was promoted K.C.M.G., and created K.C.V.O. He was also a Grand Officer of the Legion of Honour, a Commander of the Order of Leopold (First Class), and held the Croix de Guerre both of France and Belgium. He was surgeon to His Majesty the King. He married in 1881 Helen, daughter of Mr. J. R. Boyson, formerly Solicitor-General of Madras, and had one son, Lieut.-Colonel A. J. H. Sloggett, D.S.O., late of the Rifle Brigade, and two daughters, who married respectively Lieut.-Colonel Llewelyn Evans, C.M.G., D.S.O., and Major J. T. Duffin, M.C. Sir Arthur Sloggett died suddenly while walking in Regent's Park, London, with his son.

SIR JOHN ALEXANDER COCKBURN, K.C.M.G., M.D. LOND. & ADEL., M.R.C.S. ENG.

Sir John Cockburn, who died on Nov. 26th in King's College Hospital, was a prominent figure in the politics of South Australia for forty years.

John Alexander Cockburn was a Scot who came to Cholmeley School, Highgate, and King's College, London, for his education, taking the medical course at King's College Hospital. He qualified in 1871 as M.R.C.S., graduated M.B. in the University of London two years later, and in the following year proceeded to the M.D., being awarded the Gold Medal. In 1876 he migrated to South Australia and two years later became mayor of the town in which he elected to settle, thus inaugurating a public career whose utility only ceased with his death. At the age of 38 he became Premier of South Australia and until his retirement from active politics in 1898 he was found discharging many duties in many political combinations. At no time did his medical education and training seem to play much part in his political activities, though he held the portfolio of Education on more than one occasion, and made useful contributions to debates on public health and economics; he will be remembered in Commonwealth administration by his work in respect of the taxation of land and the extension of suffrage.

In 1898 he became Agent-General, and from that time forward was a familiar figure alike in social and business circles. He represented the Commonwealth at numerous important, international congresses, dealing with public health, infant welfare, national insurance, and other economic problems; he became president of the Men's International Alliance for Woman Suffrage, of the Entente Cordiale Society, the International Philological Society, and the Society for Masonic Study; he was for 17 years chairman of the Swanley Horticultural College, on the council and vice-president of the London School of Economics, was President of the Child Study Society, and he did prominent work for the London County Council in respect of elementary education. He was created K.C.M.G. in 1900.

This brief record of a busy life shows that the medical profession had reason to be proud of their colleague as a citizen valuable to his generation.

ARTHUR TEMPLER DAVIES, M.D. CAMB., F.R.C.P. LOND.

THE death of Dr. Arthur Davies at the age of 71 leaves us poorer of a sound practical physician with a charming personality. Arthur Templer Davies was the son of Dr. Herbert Davies, and grandson of Dr. Thomas Davies, both of whom lived in the City of London, and were on the staff of the London and City Road Hospitals; his father was also physician to the Bank of England, and the son followed very closely the family tradition. Born in Finsbury Square, he was educated at Charterhouse and Trinity College, Cambridge, where he took his tripos in 1880. He went on to St. Bartholomew's Hospital, qualifying in 1884, and holding office as house and casualty physician. Having taken the necessary medical qualifications, he joined the staff of the Metropolitan and City Road hospitals with which he remained associated for the greater part of his life. One of his main interests was tuberculosis, for which he found additional scope at the Royal Ventnor Hospital, but he never specialised in any narrow sense, and a breadth of knowledge fitted him for his work as physician to the Bank of England and to a number of life assurance offices. His publications also covered a wide field. He brought out an edition of his father's "Mechanism of the Circulation of the Blood," wrote on myxœdema and other dyscrasias, and delivered an oration to the Hunterian Society on Organotherapeutics, Ancient and Modern, which revealed wide study and clinical insight.

DR. A. T. DAVIES.

Dr. Davies was an original member of the Assurance Medical Society or, as it was at first called, the Life Assurance Medical Officers' Association. He took a keen interest in its work, and was successively a member of the council, secretary for four years, vice-president and president in 1916-17. His presidential address considered the heart and nervous system, in relation to the stresses of war, and, like all his contributions, was practical and to the point. "He was always," writes one of his colleagues, "modest in presenting his views, but they were invariably the result of careful thought and showed his wide practical knowledge and experience. His reports contained all essentials, and his decisions were clean-cut." During the war he acted as hon. physician to the Fishmonger's Hall Hospital for Officers.

Dr. A. G. Phear writes: "As one who was actively associated with Dr. Davies in the work of three hospitals, I should like to add a small tribute to his memory. Dr. Davies resided in the country, and after his retirement from active hospital work he was seldom seen by his friends in the metropolis, except at occasional committee meetings; he had, however, a great capacity for friendship, and an intense loyalty to his friends was a leading feature of his character. His friendships were of an enduring nature, and to meet him again, even after a long period of absence, was to return at once to the old atmosphere of intimacy. His devotion to the hospitals he served so well was remarkable; he gave of his best to each of them; but his sympathies were, perhaps, specially identified by reason of family associations, with the Royal Chest Hospital in the City Road. In committee work his sound judgment and sane outlook were invaluable assets, and, as he was always ready to see the other side of the question, his considered opinion carried great weight with his colleagues. He was a great lover of plants; much of his leisure was spent in personal attention to his garden. Throughout the latter part of his life his outlook remained fresh, and he retained to the end a certain youthfulness of mind."

Dr. Davies married in 1889 Alicia, daughter of the Rev. Robert Irwin of Trinity College, Dublin, by whom he had a son and a daughter.

ARTHUR MERCER DAVIES, M.R.C.S., L.S.A., D P.H. CAMB.,

LIEUT.-COLONEL, R.A.M.C. (RETIRED).

WE regret to record the death of Lieut.-Colonel Arthur Mercer Davies which occurred on Oct. 25th at his house at Eltham in the 77th year of his age. Davies, who was the son of a clergyman, was born at Westminster and educated at Westminster School and Queen's College, Cork, whence he entered the medical school of Westminster Hospital. He was both a hard worker and a fine athlete. He took the double qualifications of M.R.C.S., L.S.A. in 1880 and immediately entered the Army. The country was involved in the Egyptian War shortly after Davies joined the R.A.M.C., and he saw much fighting in the Eastern Sudan and in the Nile Campaign. Then came a period of service in India where his interest in public health problems became prominent. In 1889 he took the diploma of D.P.H. Camb., obtained his majority in 1893, became Lieut.-Colonel in 1901, and retired seven years afterwards. From 1904 to 1908 he was professor of military hygiene at the Army Medical School, Netley, and was well qualified for this appointment since, during his period of service in India, he had done special official work both as bacteriologist and general sanitary officer. The appointment at Netley was confirmed at Millbank, and when he finally retired from the Army he obtained a post under the London County Council as an officer in the Public Health Department.

Colonel Davies was an accurate and fluent writer, the author of a popular handbook on hygiene, a treatise on the Food of the Soldier, and many official reports and contributions to the medical press on subjects connected with public health, military hygiene, and bacteriology. He was also for many years a valued member of the staff of THE LANCET. He leaves a widow, who is the daughter of Captain David Aird, R.N.

GEOFFREY LUCAS, B.A. CAMB., M.D. DURH., L.S.A.

Dr. Lucas, who died at Las Palmas on Nov. 26th after prolonged illness, was the youngest son of Arthur Lucas (of Hitchin) and was born at Darlington in 1875. He was educated at Durham and Tonbridge, entering Caius College, Cambridge, with an exhibition, taking the Natural Science Tripos in 1899 and demonstrating physiology in the University. Four years later he qualified from St. George's Hospital with the L.S.A. diploma and held house appointments at Westminster Hospital. He then spent two years at sea with the Orient Steam Navigation Company 1904-06 before settling down to practice at Ringwood, where he became medical officer of health to the Ringwood district. It was there that he became interested in the treatment of tuberculosis, which led him to take a resident post at the Banchory Sanatorium where he remained until 1921, with the exception of the period of the great war when he was at first physician to the 1st Scottish General Hospital and later held a commission at No. XI. Stationary Hospital B.E.F. On leaving Banchory he joined Dr. Vere Pearson at Mundesley Sanatorium until he retired last year after having made several more long voyages in search of health.

Dr. Pearson writes: "Dr. Lucas was a successful sanatorium doctor because he was genuinely fond of his work and because he was a sound general physician. A succession of patients were devoted to him because he was a man of parts, with wide interests, fond of fishing and shooting, and a good bridge player, but above all because they felt he always took an essentially sympathetic and wise interest in their welfare. He lived with his patients ordering the details of their living, understanding their foibles, and comprehending their difficulties. He was a quick worker, had an able brain, and was well versed in other branches of medicine besides tuberculosis. When during the war he practised as a general physician in the wards of the 1st Scottish General Hospital, Aberdeen, he did a certain amount of teaching as an assistant to Prof. Ashley Mackintosh. He would quickly grasp the gist of modern advances in medicine, and generally kept well abreast of these whether they were directly, or only indirectly, connected with the subject of pulmonary tuberculosis, which was, of course, the disease from which most of his patients suffered during the greater part of 20 years of his working life. By many of these he will be missed."

Dr. Lucas leaves a widow who with her two children has recently taken up residence in Australia.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 23RD, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 279 (last week 172); scarlet fever, 3673; diphtheria, 1902; enteric fever, 49; pneumonia, 1263; puerperal fever, 51; puerperal pyrexia, 116; cerebro-spinal fever, 10; acute poliomyelitis, 9; acute polio-encephalitis, 2; encephalitis lethargica, 19; dysentery, 10; ophthalmia neonatorum, 116. No case of cholera, plague, or typhus fever was notified during the week.

Of the small-pox cases 84 were reported from the County of London, as against 64 last week. These were distributed as follows: City of London, 1; Bermondsey, 2; Bethnal Green, 13; Camberwell, 16; Hackney, 6; Islington, Kensington, Lambeth, Lewisham, each 1; Poplar, 3; St. Pancras, 5; Shoreditch, 6; Southwark, 19; Stepney, 10.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Nov. 26th–27th was as follows: Small-pox, 310 under treatment, 8 under observation (last week 240 and 17 respectively); scarlet fever, 2828; diphtheria, 2663; enteric fever, 89; measles, 307; whooping-cough, 109; puerperal fever, 32 (plus 14 babies); encephalitis lethargica, 125; poliomyelitis, 7; "other diseases," 16. At St. Margaret's Hospital there were 8 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 5 (4) from enteric fever, 23 (4) from measles, 9 (2) from scarlet fever, 22 (1) from whooping-cough, 43 (8) from diphtheria, 76 (17) from diarrhœa and enteritis under two years, and 75 (10) from influenza. The figures in parentheses are those for London itself.

The single death from enteric fever outside London was reported from Acton. Diarrhœa accounted for 8 deaths at Liverpool and 6 each at Manchester and Salford. In Liverpool there were 5 deaths from diarrhœa and 4 from scarlet fever. Manchester and Wigan each reported 4 deaths from measles and West Ham 3.

There was no death from small-pox in the returns received from areas outside greater London, the county boroughs, and great towns for the month of October last.

The number of stillbirths notified during the week was 265 (corresponding to a rate of 42 per 1000 births), including 68 in London.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

CHILDREN AND YOUNG PERSONS (EMPLOYMENT AND PROTECTION) BILL.

In the House of Commons on Nov. 29th Mr. SORENSEN moved the second reading of this Bill. He said that there were hundreds of thousands of young persons working hours which he could only describe as perfectly abominable. This had an adverse effect on the health of the community, and of the young people in particular. There were still a number of young people and children who were adversely affected in industries which employed lead paint, and one of the clauses of this Bill prohibited entirely the employment of young persons in those concerns, except under very drastic conditions regarding apprentices. There was another clause in the Bill which dealt with the effect on young life of the lifting of weights that were altogether disproportionate to the size and strength of the young lads. The measure also protected young people employed in connexion with theatrical entertainment. The chief point of the Bill was that there should be no children under the *age of 13 employed, except those who were lawfully employed* when the measure came into operation. Between the ages of 13 and 16 the Bill provided that the total number of hours worked should be 88, or 8 hours per day. No child should work before the close of school each day. Between the ages of 16 and 18 the total number of hours worked should be 48, or 9 hours per day. Under the age of 18 there should be no Sunday work, and one half day per week should be guaranteed to the children and young people of the country. It was also provided that under the age of 16 no young person and no children should be employed in the coal-mines, and between 16 and 18 only those should be employed who had obtained a certificate of medical fitness.

Dr. MARION PHILLIPS seconded the motion for the second reading.

After some debate,

Mr. CLYNES (Home Secretary), said that the attitude of the Government towards the Bill was one of the completest goodwill and sympathy, but most of the ground covered by it had already been covered by Bills introduced by the Government, or Bills which they intended to introduce. He suggested that the purpose of the promoters might have been served by the debate that day, and that they should trust to the Government measures to which he now referred, and that this Bill might be withdrawn.

Dr. VERNON DAVIES said that the sympathy of all parties in the House was definitely with children and young persons, but those who had had experience of child workers or young workers in textile factories recognised that Mr. Sorensen in bringing in this Bill had taken on a colossal task and one which was really beyond the competence of any private Member. That task could only be adequately discharged by means of the large experience and sympathetic help of the Government. He welcomed the advice of the Home Secretary that the promoters should be satisfied with having raised the subject.

In reply to Mr. SORENSEN, Mr. CLYNES said that he could give an assurance that when the Government had disposed of their Factories Bill, which covered only those employed in factories, they were quite eager and ready to try to cover the remaining groups by a separate Bill which would be introduced as early as possible.

Mr. SORENSEN asked leave to withdraw the Bill, but leave was refused.

Lieut.-Colonel FREMANTLE said that it might be necessary to withdraw the Bill at a later stage, but personally he hoped that Mr. Sorensen would go through with it. The medical side of the Bill was extremely important, and he hoped that it would not be forgotten even if the Bill was withdrawn. There was a clause in the Bill which dealt with trades which had been neglected in the health services so far—the mercantile marine and mines.

After further debate,

Mr. STRAUSS moved that the debate on the Bill be adjourned.

On a division *the motion for adjournment of the debate* was carried by 152 votes to 45.

EXPENDITURE ON PAUPER LUNATICS.

Mr. GREENWOOD, Minister of Health, informed Major GLYN that the expenditure of Poor-law authorities in England and Wales during the year ended March 31st, 1928, in connexion with the certification and cost of conveyance of lunatics, was £92,007.

HOUSE OF LORDS.

THURSDAY, NOV. 28TH.

MENTAL TREATMENT BILL.

Earl RUSSELL, Parliamentary Secretary to the Ministry of Transport, in moving the second reading of the Mental Treatment Bill, said that he was not the normal representative of the Minister of Health in that House, but he had been selected for the duty on account of the experience which he acquired a good many years ago on the London County Council, when for several years he used to visit at least two asylums every week and acted for some years as Chairman of Hanwell Asylum. His interest in, and knowledge of, the subject was revived and increased when the Royal Commission was appointed in 1924 and of that Commission he was a member. It sat for two years and reported in 1926. He had been responsible when on the other side of the House for asking why that Report had not been acted upon and why nothing had been done. It therefore gave him special pleasure to present to their lordships a Bill which dealt at any rate with the important parts of the recommendations of that Commission. The Bill did not profess to create an entirely new code. That was recommended by the Royal Commission and would be very desirable, but the system under which legislation was conducted made any Government reluctant to undertake too large and too comprehensive a Bill on account of the difficulties of Parliamentary time. Therefore this Bill which was now before the House was a comparatively small Bill, although the amendments which it made were, from the point of view of the treatment of patients, very important. The Government would welcome any improvements that their lordships could suggest in the passage of the Bill through the House. It had been considered for several years by successive Ministers of Health with great care and they believed that they had arrived at the best solution, but it might well be that some useful amendments might be suggested. The Bill was not in its main features entirely new to their lordships. Lord Onslow had introduced a Mental Treatment Bill in 1923, to which their lordships gave a second reading, and which, *he thought, was based on the same principle, so far as the* major issues were concerned, as this Bill. He had no fear but that their lordships would welcome the present Bill as heartily as they welcomed that one.

Some Extracts from the Report of the Royal Commission.

The Royal Commission was presided over by Mr. Macmillan, and no opportunity should be lost of expressing the sense of public gratitude that they all ought to feel for his conduct in presiding over that Commission. The subject was extraordinarily difficult and complex. The Commission consisted of twelve persons drawn from all political parties and from all shades of thought, and, after going exhaustively into all these matters, the chairman succeeded in *presenting a Report which was unanimous*, except in one particular. That was an achievement and was also an encouragement and a support to anyone who attempted to legislate on the recommendations of that Commission. He would quote two or three short sentences from that part of the Report, which would strike the note on which he wanted to invite their lordships to deal with the Bill. The Report said:—

> "The keynote of the past has been detention; the keynote of the future should be prevention and treatment."

And, further:—

> "Contrary to the accepted canons of preventive medicine, the mental patient is not admissible to most of the institutions provided for his treatment until his disease has progressed so *far that he has become a certifiable lunatic.* Then and then only is he eligible for treatment. . . . Certification should be the last resort in treatment, not the prerequisite of treatment."

If they were to adopt the analogy that the Royal Commission thought they ought to have between mental disease and any other forms of disease, it surely would be rather absurd not to treat a disease until some symptom had reached a very aggravated stage. What would be thought of modern medicine if they did not treat a case of scarlet fever unless and until the patient had come out in spots and was distributing infection to the community? What would be thought if they did not treat people with an ordinary fever until they had shown that they had it by running out into the cold with a temperature of 102°, and running the risk *of pneumonia? This idea was not as new as might* be supposed. As far back as 1860 the Commissioners in Lunacy stated:—

> "The chances of recovery are much greater when the patients are placed under treatment in an early stage of the attack than when the disorder has been allowed to remain unchecked for some time."

Again, in their Report for the year 1891 they stated:—

> "For 40 years and more we have directed our endeavours towards securing the early treatment of mental disorder upon

which, according to all experience, recovery so materially depends."

Sir Frederick Willis's Statistics.

The present Bill was an effort to give statutory form to these aspirations, and he thought it was justified by a sentence which he would quote from some articles in the *Times* that were written by Sir Frederick Willis, a former Chairman of the Board of Control, dealing with the present position. He called their lordships' attention for the moment to this sentence:—

> "The evolution of asylums from mere places of detention to real hospitals has taken place."

That was to say, an asylum was no longer a prison. It was no longer a place where they merely confined a man in order that he could not do harm to himself or others. It was not primarily a place where they confined him for that purpose, but it was a place where they sent him for curative treatment in the hope that it would enable him to rejoin his fellow men. In that same article there were some very interesting statistics of the incidence of insanity which are as follows:—

Incidence of Insanity.

A = First admissions per 10,000 population.

Year.	A.	Year.	A.	Year.	A.
1869	4·07	1909	5·04	1923	4·93
1879	4·46	1919	5·25	1924	4·41
1889	4·58	1921	4·91	1925	4·40
1899	4·94	1922	4·91	1926	4·48

Recovery-rate.

Number of Recoveries to 100 Admissions.

Year.	A.	Year.	A.
Average—			
1869 to 1878	38·84	1920	32·21
1879 „ 1888	39·91	1921	32·52
1889 „ 1898	38·81	1922	32·29
1899 „ 1908	37·22	1923	31·61
1909 „ 1918	32·69	1924	34·86
1910 „ 1919	32·27	1925	31·84
		1926	31·85
		1927	31·43

The first statistics dealt with the incidence of insanity, and ran from the year 1869 to the year 1926, and this was the comment that Sir Frederick Willis made upon them:—

> "These figures support the statement that the incidence of the disease has not been materially reduced."

The change per 10,000 of population was from 4·07 in the first year to 4·48 in the last year. They also did not support the contrary statement that was sometimes made that insanity was very largely increasing, and to that extent they were satisfactory. They were very hopeful that, if the system proposed by this Bill was adopted, the recovery-rate, or rather the number of recoveries, might be improved. Perhaps he should make it clear that the technical recovery-rate, if it meant the rate per hundred of certified persons to recover, might very well become worse, because they were hoping that all the people who were successfully treated under this Bill would never become certified lunatics, and would therefore be taken out of the recoverable class to which that percentage applied. But they hoped that the total recoveries would be larger and that they would be more quickly effected.

Three Important Points.

Describing the Bill itself, the noble lord said that it really only contained three main matters of importance. The first, Clauses 1 to 4, related to the voluntary boarder, a person who was sufficiently intelligent to ask for treatment, and to wish for treatment. Clause 5 dealt with the temporary boarder, a person who was not in that position but who had to be treated against his will, but only for a time. Those were two important points dealing with patients. Clauses 11 to 15 gave a reconstitution of the Board of Control, to which a great deal of importance was attached. It was enough to say that the Board of Control were now constituted under an Act of 1845, to suggest that possibly the time had come when some amendment might be useful. The other clauses in the Bill were less important. Clause 1 covered a person suffering from mental disorder who was desirous of voluntarily submitting himself to treatment, and who made a written application. He might, without a reception order and without formality beyond the written application, be received as a voluntary boarder, and, in the case of an unmarried person under the age of 18, the will, the voluntas, was transferred to the parent or guardian. That was possible now in the case of most licensed houses. It was sometimes possible in the case of single care, but it was not possible for the poorer class of the community. The present rate-aided mental hospital, or, as it used to be called, the pauper lunatic asylum, had no provision for receiving the voluntary boarder, and at the Royal Commission evidence was given of most distressing cases of people who felt they they were becoming more and more unstable, more and more upset, but that a little rest, a little treatment, would probably set them right again. But they were unable to obtain that treatment from a recognised county asylum, because there was no power to admit them, and they had to go on until they had become so bad that they were certifiable before they could be treated. That proposition has only to be stated to show its absurdity.

Single Care of the Voluntary Boarder.

There was another point, of course, about the voluntary boarder, and that was the danger which any doctor suffered who took such a person into single care, and who was always liable to prosecution for harbouring an uncertified lunatic. He was not allowed to take charge of a person who was certifiable unless he was certified. These people were not intended to be certifiable people; it was hoped that they would never reach that stage, and there would be some protection here in the fact that the early treatment was recognised as a possibility. He called special attention to Subsection (3) of Clause 1, by which a person who was received as a voluntary boarder, although he had entered voluntarily, was not allowed to leave at a moment's notice. He must give 72 hours' notice. In a sense it might be said that they were imposing on the voluntary person imprisonment; in a purely legal and technical sense that was, of course, absolutely correct; but it was quite plain that it would not be safe, and it would not be in the interest of the patient, to allow him to leave at a moment's notice, since the very occasion when he would be insisting on leaving, and requiring to leave, would probably be just that occasion when he had become so mentally unbalanced as not to be able to look after himself or give himself proper care. This period of delay of 72 hours, therefore, which was by no means necessarily interposed in every case, but only where the medical officer thought it necessary, gave the opportunity either for the patient, as very often happened, to come back to a better mind before the 72 hours were up, and to say, "I will withdraw my notice and stop," or, if it had unfortunately become necessary, to proceed to the extreme measure of certification. Without that provision, it might well happen that the treatment would fail of effect and that the patient would destroy the whole value of it by his impetuous action in some special moment of excitement, or owing to some irritation caused by something that had happened. What were the protections of those patients? In Clause 2 their lordships would notice that notice of a patient's reception was to be given within two days to the Board of Control. That notice was equally to be given to the Board of Control if he died in or departed from the institution where he was being treated; and, finally, should the patient become incapable of volition, should he no longer be able to exercise a choice, or a will, he was not to be kept as a voluntary boarder for more than a month; but before the end of that period he had to be discharged unless either he had again become capable of volition—a thing which often happened—or steps had been taken to certify him. In all these cases the Board of Control was the body that the public might rely upon to see that the patient was not unfairly treated.

The Earl of ONSLOW: Will the voluntary boarder come under the provisions of Clause 5, temporary treatment, if he becomes incapable of volition?

Earl RUSSELL: Yes, and I think that that period of one month would probably be used in order to apply Clause 5 to him. Continuing, the noble lord said he hoped that might be possible in every case where it was not necessary to proceed to full certification. The effect upon the minds of the Royal Commission of all the evidence they heard, including the evidence from the Board of Control, was that the real safeguard for every person, either insane or alleged to be insane, or partially insane, who was detained or under treatment anywhere, was the existence of the Board of Control itself—and by this Bill the powers of the Board of Control were to some extent increased. If notice was given to the Board of Control there could be no secrecy, if a visit was paid by the Board of Control there could be no concealment, and there could be no deception of the experienced officials that they would send to visit. That was really far more of a safeguard to patients than any other safeguard, but he would deal with that more fully on Clause 5. Under Clause 3 a commissioner, that is, not necessarily a member of the Board of Control, but a commissioner as provided by a later clause—an official visitor of the Board of Control—might at any time visit a voluntary boarder, and he might report on the case, and then the Board of Control, if they were of opinion that his state of health was unfit for him to remain as a voluntary boarder, might order the superintendent to discharge him, or might take steps to deal with him, if necessary, as a person of unsound mind. With those protections there could be very little to be said against the voluntary boarders. The man entered of his own free will, his maximum detention was 72 hours if he gave notice to leave, his maximum detention was one month if he became incapable of free will, and at all times he had over him the controlling hand of the Board of Control, who could give orders as to what in their view was proper to be done in his case. That did not seem to the Minister of Health to leave much opportunity for abuse.

The Temporary Boarder.

Now he came to what was perhaps a little more contentious—namely, Clause 5. That clause provided for what was called the temporary boarder, a person who was suffering from mental disorder, incapable of volition and likely to benefit by temporary treatment. In his case, if an application was properly made and a proper medical certificate was given, he might be detained for six months. That period of six months was a period in which, according to the evidence and the statistics, a very large number of recoveries took place. It might not be, perhaps, as long a period as would really be useful, but the Minister of Health had been very moderate in his estimate and had only suggested detention for six months. In what way did the circumstances in which such a person was detained differ from the circumstances of full certification? So far as the *application was concerned, there was no great difference on* which he need dwell. The application must either be made by the husband or wife or a relative. If not, it must state why it was not made by them and what the interest was of the person making it. The patient must then be examined by two doctors. In the ordinary case of certification of the rate-aided patient only one doctor was required. But the great difference was that there was no interposition of the justice of the peace. In the view of the Government the two doctors provided a far greater safeguard than any number of justices of the peace, and it was provided that one of the two doctors was either to be his usual medical attendant—that was in Subsection 8—or, if not, he was to be an official person officially appointed who could have no interest of an improper character in the matter. The Royal Commission suggested a rather different form of treatment for the same purpose by what was called in their report a provisional order, and they did introduce the justice of the peace. The provisional order had been thrown over by the Ministry of Health because, although the intention was to remove the stigma of certification, it was fairly obvious that in a very short time it would have been held as exactly equivalent. One had the doctor, the justices, and all the other incidents of full certification. Therefore, this suggestion was put forward. What harm was that likely to do? He would read a short quotation from the report of the Royal Commission.

> "That in practice instances of sane persons being wrongfully certified or improperly detained must be of the rarest occurrence. We *think it proper to record that in none of the cases* which were investigated by us were we satisfied on the evidence that improper detention had been suffered."

They went on to say in connexion with another matter:—

> "Ill-usage is not deliberately or systematically practised in mental institutions."

His next sentence was again a quotation from Sir Frederick Willis:—

> "The only hope of reducing the incidence of insanity and improving *the recovery-rate is to alter the law so as to allow* and encourage the early and skilled treatment of persons mentally ill."

On the point of the justices of the peace the Royal Commission said that they reluctantly recommended retaining the justices of the peace. They recommended it merely because they were afraid of Parliament and uninformed public opinion. But they added this sentence to which their lordships would give full weight:—

> "If we were free to consider exclusively the medical treatment of the patient we should have little hesitation in accepting this suggestion."

That was the suggestion of certification without the justices.

Modern Methods in Mental Disease.

There still existed in some places the feeling which was aroused, possibly naturally and justifiably, nearly 100 years ago against confinement in asylums and asylum treatment. For that feeling there existed no justification to-day. Every person connected with these institutions devoted his whole thought and his whole attention to curing his patient if he possibly could and, if he could not entirely cure him, at least to ameliorate his condition. The fear which then existed was a fear which need exist no longer. So far as rate-aided institutions were concerned, there was no temptation to them to detain the patient one day longer than they could help. They were full; they were overfull; they had difficulty in finding accommodation. The trouble recently had rather been, perhaps, the other way—that sometimes people were discharged almost before they were fit to be at large. He submitted that they should recognise now that a doctor was not that sinister figure which in former times he was represented to be, anxious simply to confine a man to a dungeon for life, but that he was treating mental disorder in exactly the same way as he treated any other disease, with a sole view to its cure. When they used such phrases as "liberty of the subject"—and no one attached more importance to real liberty of the subject than he did—let them reflect upon what the circumstances were. If their daughter had a fever was she not restrained in bed instead of being allowed to run out in the cold air to die of double pneumonia? They did not invoke the justices to do that. They did not even invoke the ordinary certificate. They did it as a matter of course. If *one of* their lordships was delirious and in a fever he would be without volition within the meaning of this Act for the time; he would not know what he was doing. He would not appreciate that he was being treated. Nobody hesitated in those circumstances to restrain personal liberty until the time when it was necessary to restrain it was passed, and that restraint was, of course, in the obvious interest of the patient. When the patient had recovered the patient was grateful for it. Precisely the same thing happened *in the case of mental treatment.* The vast majority of these patients were grateful when they recovered for the treatment they had received and recognised the good that had been done them. Therefore they ought not to be led away by mere words on this matter.

Visits to Mental Patients.

There was still another thing to be remembered, and that was the number of visits which might be paid to these patients. *First of all, there was the Board of Control* entitled to visit at any time and as often as they liked. Then there was the superintendent of the asylum himself who, of course, visited his patients regularly, though they might regard him as an interested party. In the case of the rate-aided asylum, there was the visiting committee or, in the case of the licensed house, the visiting justices. Then there were the patient's friends who were at liberty to visit the patient and hear his own account, for what it was worth, of his treatment. Finally, in the case of patients who had property, they had the Lord Chancellor's visitor. So their lordships might take it that these people were, and would be, well protected. In Subsection 9, in addition to the Board of Control's visit, within one month the patient was to be visited by two members of the visiting committee or, if not, by two of the visitors of licensed houses, and that after that visit they were to sign a statement either to the effect that it was proper the patient should continue to be detained, or that it was not proper, *and then they should within two days again report to the* Board of Control stating their opinion.

In Subsection 12, dealing with the powers of the Board of Control, it was provided that at any time they might order that a person received as a temporary patient should be discharged, or that steps should be taken to deal with him as a person of unsound mind. He thought that the public really had no reason to fear these provisions. The whole object nowadays was to assimilate the treatment of mental disease to the treatment of other disease. For his own *safety, and sometimes for the safety of other people, it was* unfortunately essential that the patient should be placed under restraint and deprived of his liberty, which was sometimes only an incident and might be of only a few days' duration. That it should be necessary to put him upon the stigma of full certification for that purpose, or that he should have become so bad that he must be fully certified before they treated him at all, was a thing which could no longer be tolerated. The provisions in this Bill were likely to do a great deal to prevent people ever reaching the stage of certification, and to empty, in that sense, the certified wards, and to send the people back without that stigma which was a very serious stigma both in the matter of reputation and in the matter of employment.

Reconstitution of the Board of Control.

Clauses 11 to 15 were the clauses which reconstituted the Board of Control, and this reconstitution was in accordance with the views which the Royal Commission expressed. As a member of that Commission he welcomed it, and he would explain the present position. There were about twelve Commissioners, some medical and some legal. They had the duty not only of regulating policy and principles, but of visiting all these various institutions which this and the principal Act imposed upon them. The result had been that they were so busy running about the country that they were never able to have real consultative committee meetings in London, as they should have, to decide upon the principle and the policy to be applied. These clauses proposed to divide the Commissioners into two parts. There would be five in all who would constitute the Board of Control, and the idea was that those five should have primarily as their duty the coördination of the control of all the general matters relating to administration, of which there were a great many—provision of drugs, the qualification of nurses, the staffing of asylums, the construction of asylums, and the thousand and one matters of policy that were proper to be centred and fully discussed: and those five people would be able to meet regularly, and without interruption, and discuss these matters. They would be called the Senior Commissioners. There would be other Commissioners, and there would also be Assistant Commissioners, and those Commissioners and the Assistant Commissioners would primarily do the visiting that was required. Clause 13 provided that one Commissioner might carry out visits which were at present sometimes required to be made by two. In a great many cases the law required two Commissioners to visit when there was no sort of reason why more than one should do so. It had been found impossible to carry that out for some time now on account of the difficulty of the numbers; but under this clause, as the Commission would now be constituted, the visiting would primarily be done by the Junior Commissioners and the Assistant Commissioners.

Five members of the Board of Control would meet regularly and control policy, and would, of course, themselves visit these institutions from time to time in order to keep abreast of what was being done, and to learn with their own eyes what was going on. Under Clause 11 there was to be a Chairman. That was in Subsection 1. In Subsection 2 there was to be a legal Commissioner, a medical Commissioner and a woman. That accounted for four, leaving one place vacant which could be filled up by another medical Commissioner, or as might be thought most desirable. Ths existing Commissioners who were not members of the new Board of Control would continue as Junior Commissioners, although that word was not used in the Bill, and there would also be Assistant Commissioners. Subsection 7 provided that such salaries should be paid to these Commissioners as the Minister and the Treasury might determine. The Royal Commission expressed a very strong view that the position of the Chairman of the Board of Control was so important and so responsible that a substantial salary should be attached to it. Clause 12 mainly provided that the Chairman should be primarily responsible for the arrangements. The only other clause he need call attention to was Clause 15, giving a power to make rules, which was, he thought also, in the Bill of 1923. The Royal Commission attached a great deal of importance to this reconstitution of the Board of Control, because it became very evident to them that it was impossible for the work to be done as it should be done under the present Constitution, and perhaps it was, from the point of view of administration, a reform which would be as useful as any reform could be.

Clause 6 required the local authorities to provide the necessary accommodation for temporary patients. It was not likely to increase their total accommodation. In fact, they hoped on the whole that in the end it would diminish it. Clause 7 provided for the appointment of a Visiting Committee. Clause 8 provided for the circumstances which had arisen under one or two Private Acts, such as the Maudsley Hospital, where special circumstances applied.

Granting of Certificates; The Question of Immunity.

Coming to the miscellaneous clauses, he would call attention to the substituted Subsection 2 in Clause 16, which was an attempt to provide some further protection for the medical men who gave certificates. Recent actions, particularly, perhaps, the Harnett case and other actions, had not unnaturally frightened medical men, and they were very chary of giving certificates for which they might be shot at, particularly as in the Harnett case, twelve years later. It was a very grave responsibility for a professional man to take. It not only costs him money, it might ruin him professionally; and the result was that after that case there was a very great shyness on the part of doctors in giving these certificates in proper cases. No one could blame them for that. They were not paid more than an odd guinea of two and they were taking a very serious risk. The Royal Commission was pressed by the doctors to give them complete immunity. Those on that Commission who were lawyers felt that that would be contrary to the principles of the law, and that they could not go as far as that. The doctors themselves said, when asked: "No, we are not asking, and we do not ask, immunity for a rascal or a rogue or even for a thoroughly reckless person. But we do say it is a little hard that people who are exercising their profession honestly and to the best of their ability should be shot at in this way."

The Earl of ONSLOW: Does this immunity apply to certificates regarding people not capable of volition under Section 5 of this Bill?

Earl RUSSELL: I am not sure, but I think it is intended to.

Viscount BRENTFORD: Yes, if the noble Lord looks at Subsection 2, he will see it refers to anything done under this Act.

Earl RUSSELL: Yes, I think so. I would not like to answer offhand, but I think it applies to this, too. Continuing, the noble lord said that the Royal Commission considered this matter very carefully. The legal members gave attention to it, and took advice for several days and talked the matter over, and finally recommended the form of words which were now embodied in the substituted Subsection 2. The effect of these words was not to give the doctors immunity, but to shift the onus.
The Bill said:—

> ". . . such proceedings shall . . . be stayed on such terms as to costs and otherwise as the Court may think fit, unless the Court is satisfied that there is substantial ground for alleging that such act was done in bad faith or without reasonable care."

He could not help feeling that that would present some difficulty to His Majesty's judges, but there were statistics containing somewhat similar provisions on which they now and then acted. There was a statute about vexatious actions, and other statutes of that kind. What it really meant was that the plaintiff would have to satisfy the judge *in limine* that he had some sort of a case. It did not follow that it was a good case, or that he would win it, but he would have to satisfy the judge at an early stage that he had a prima facie case and that there was something which properly required investigation. It was not by any means a final protection to the doctors—very far from it—but it was some protection, and he hoped it might do something to protect them from suffering from legal actions when they had done the best they could.

Urgency Orders.

Clause 17 made urgency orders applicable to rate-aided persons. Curiously enough, urgency orders were only applicable to private patients. Why, he did not know. It was a useful form, and the rate-aided person could only be—so to speak—taken in charge if he was found wandering or in other circumstances when he was dangerous to himself or to others. This provision would give the opportunity of making an urgency order in all proper cases. Clause 18 was one to which a good deal of importance was attached. The people maintained in rate-aided mental hospitals were called pauper lunatics, the place in which they were maintained was called a pauper lunatic asylum, and the whole thing was done under the poor-law. The extraordinary result of that legislation was this. Their lordships would hardly credit it, but there was no doubt that what he was saying was correct. If a person became suddenly mad in the street, was taken by a relieving officer to the workhouse, was there certified and sent to an asylum, even if subsequently it was discovered that he was a person of means, even if he repaid to the poor-law authorities the whole of the expenses to which they had been put, he became and remained a pauper. That was clearly a ridiculous state of things. It was desired now—and the passing of the Local Government Act last session made it possible—to assimilate the treatment of this form of disease with the county medical services. This clause provided that:—

> "A person shall not be deemed to be in receipt of poor relief or be deprived of any right or privilege or be subjected to any disability by reason only . . ."

of anything done to him under this Act or under the principal Act. It was time that was done.

Clause 19 was merely a provision enabling county councils to use those workhouses which would come into their possession under the new Act. Clause 20 carried out what he had just spoken about, the change of name. The change of name implied a change of spirit, and the treatment would be different, and therefore it was appropriate that these hospitals and the people who were treated in them should receive new names and new appellations. He would say one word about the things which were not done under this Bill. It had not made a complete code for obvious Parliamentary reasons. It had not assimilated completely the method of certification in private and pauper cases which for historical reasons no doubt differed in the Lunacy Act of 1890. That would have meant rewriting the complete code and it had therefore been left over.

Licensed Houses.

The Bill had done two things which met the points that mattered; it had given the urgency order to the rate-aided persons and had removed the pauper stigma from the rate-aided cases. Neither had the Bill dealt with the vexed question of licensed houses. So vexed was the question of licensed houses that it was the only question on which the Royal Commission disagreed. There were six on one side and six on the other. But the time had come when Parliament must some day or other make up its mind what it was going to do about licensed houses. The licensed house was an institution for the treatment of insanity, which was run by a doctor or several doctors, or at any rate had to be staffed by a doctor, whoever was the owner, for private profit, and the public were perfectly right, no doubt, in looking with the very gravest suspicion upon places of that kind.

When Parliament last dealt with this question in 1890, it adopted a quite illogical and a quite indefensible half-way house attitude. The existing private licensed houses were allowed to go on; no new licensed houses were allowed to be created. No number of beds were allowed to be added to those already in existence in the licensed houses then existing. In effect, Parliament said: "We are not quite sure whether this thing is so bad that it ought to be swept away altogether, but at any rate we are not going to let it be increased," and the number of beds in 1890 was the number of beds up to this date. That was not a logical attitude. He would not say which of the two other attitudes was right, but it was obvious that one must be right. Either a licensed house was a necessary institution serving a beneficent purpose in the case of a private patient who could afford to pay for treatment, or it was an evil that ought to be swept away. Actual inconvenience was caused by this because in fact licensed houses were not so geographically distributed as to be convenient. That had nothing to do with this Bill, but as he had mentioned what was not in it he thought he ought to mention the matter on which the views of the Royal Commission were divided half and half. He had been through the Bill very carefully with the Chairman of the Royal Commission and he had authorised him to say that he welcomed it as a most useful instalment of the reforms which the Royal Commission proposed.

Liberty of the Subject.

Viscount BRENTFORD said that for a certain time while the Royal Commission was sitting he occupied the position of Minister of Health, and therefore he was in somewhat close touch with the Board of Control and the questions, so far as the administration was concerned, which were submitted to the Royal Commission. For many years the question how best to deal with insanity had troubled Parliament and the country, and he was very glad to be able to associate himself with Earl Russell in what he said in regard to the modern view of the treatment of insanity—that it should be taken at the earliest possible stage and be put as far as it could be put upon the same lines as ordinary disease. But, of course, there was distinctly a difference between the disease of insanity, whether it was mere lack of volition or complete insanity, and every other physical disease to which flesh was heir to. That was, of course, the question of the liberty of the subject. For a couple of hundred years at least there had been commissions and inquiries and Acts of Parliament of every kind, and before the Act of 1890, which was really the foundation of the Lunacy Laws, there were 40 or 50 Acts dealing with this question. Running throughout the Act of 1890 was noticeable the meticulous care of Parliament for the liberty of the subject. While he (Lord Brentford) did not intend to oppose the second reading of the Bill, there would be certain points to be raised on the Committee stage which ought to be mentioned at once because they appeared to be of considerable importance. He hoped Earl Russell, when he had heard what these points were, would consult with him as to necessary amendments in order that the Bill might go through in a satisfactory form. He wanted to clear uncontentious points out of view, and he entirely accepted the view of the Commission that there was no ill-treatment, or rather that no cases of ill-treatment were proved to them. That, however, did not quite go far enough. Earl Russell had told them quite frankly that there was both Parliamentary hesitation and uninformed criticism in regard to the question of the liberty of the subject. Under the existing law whenever a man or woman had to go into one of these homes, private homes, single-case homes, or rate-aided institutions, there had to be an inquisition of some kind or another by some kind of judicial authority. The great inquisition had now almost gone into desuetude, that was the inquisition by a master in lunacy with, or without, a jury. There was a petition for a reception order certified by two medical men, and then there was a safeguard that the petition must be presented to a special justice of the peace who had the power, if he so desired, to see the patient before the reception order was issued. That was not only a safeguard for the patient, but for the medical men themselves. Earl Russell was proposing to take away a great deal of the legal responsibility of medical men and at the same time he took away the one great safeguard both for the medical men and the patient who was supposed to be placed in a hospital.

The Young Person under Eighteen.

If one looked at the Bill it would be seen that the voluntary boarder was dealt with under Clause 1. Earl Russell referred to such a person as a man or woman who desired—rightly and sensibly desired if they liked—to place himself or herself under control for the purposes of being benefited by medical treatment in a mental hospital. He agreed that if a man or woman had sufficient sense to realise the desirability of treatment he or she might quite rightly place himself or herself there, but the noble Earl had referred to another case, and that was the case of a young person under the age of 18. Why 18 was fixed he (Lord Brentford) did not know, but he supposed that anybody over 18 was for the purpose of that clause to be treated as an adult entitled to put himself into a mental home. The case of the young person under 18 he thought should be most carefully considered by their lordships' House, which had always protected the liberty of the subject. Take the case of a boy or girl of 17 who might be a little silly, as the expression was used in some parts of the country, who might be also a great burden at home, troublesome to the parents. That young person, without any assent on his or her part, a boy or girl of 17, nearly 18, might be placed as a voluntary patient—there was not much that was voluntary about it—on the written request of the parent, the guardian, or a person who acted in the position of guardian. In his (Lord Brentford's) view the Bill needed amendment in that respect. There was not even to be a medical certificate, much less any judicial authority. It was merely left to the parent or guardian to say: "I am very worried by Tom or Jane, who is very troublesome. I will lock him (or her) up." Under the Bill he thought it was quite possible to do that. Of course he knew that there was a Board of Control over and above all cases, but Earl Russell had tried to prove too much in regard to the position of the Board of Control. If the control of the Board was so effective in regard to these people who might be placed under voluntary detention, or under Clause 5 in temporary detention, because they were incapable of volition—why trouble at all about medical certificates, why trouble at all about the reception order which still, he took it, would exist under the old law for the man who was flagrantly and patently insane? It was rather remarkable to retain, as the noble Earl said in bringing in his Bill, the greatest safeguards, including the judicial safeguard, in the case of the man who was flagrantly and patently insane, and whom everybody would put into an asylum, while for the more doubtful cases the safeguards were swept away. The noble Earl must reconsider the first clause of the Bill. As regards adults, he (Lord Brentford) would prefer the age to be 21 rather than 18, and he was not sure that the young man or woman of 18 or 21 ought to be allowed to put himself or herself into a mental hospital for treatment without any medical or judicial certificate. That was the position under the Bill, and he was not satisfied that parents or guardians or "any person who undertakes or performs . . . the duty of a parent or guardian"—it was a curious expression—ought to be allowed so put people at the age of 18 into homes for medical care.

The Meaning of "Volition."

If they turned to Clause 6 relating to the temporary treatment of persons without full certification, they found a reference to people who—he thought this was a new expression; he had not been able to find it in any Act of Parliament relating to lunacy—"were incapable of volition." It was difficult to know quite what that meant. The gradations of lunacy were so many and shaded from one to another so easily that he thought the noble Earl had tried to find a new expression to provide for these temporary cases. He wondered whether the noble Earl would consider him (Lord Brentford) incapable of volition if he said: "I am blowed if I will go into a hospital." He would use no stronger language than that. The patient might be slightly insane, but he had enough volition to say: "I will not go in"; and yet he might be a person for whom treatment would be highly desirable. He thought that this portion rather needed amending, and he was certain that there must be an amendment dealing with the question of a judicial decision. The Government had thrown over the Commission and the report which Mr. Macmillan, Earl Russell, and the present Attorney-General had signed. The noble Earl had signed that document, as did his colleagues, including the present Attorney-G and though they signed it with reluctance the at they signed it with reluctance meant th

The Earl of Cranbrook said that some noble Lords had a very poor opinion of the medical officers in charge of institutions. He could not conceive it possible that any medical officer would receive an unfortunate child into an institution who had been brought there by his parents if the child was in a completely sane condition. One point that had not been touched upon was the question of authorities being allowed to have out-patient clinics. That would be a great step in advance. He hoped the time would soon come when out-patient clinics for the treatment of incipient cases, or cases already discharged, would be established all over the country.

Reply to the Debate.

Earl Russell, replying to the debate, said he regarded out-patient clinics as a very valuable feature in treatment. As to the question of protection for the medical profession the provision in the Bill was the very best that all the legal skill brought to bear on the matter could think of. But if their lordships were prepared to extend it further he did not know that he would be prepared to oppose it. As to the views put forward by Lord Brentford perhaps the noble Lord would consult with him, or, better still, with the Minister of Health, in order to see if anything could be done to adjust Lord Brentford's view with the opinion held very strongly by everyone who knew about the matter. He (Lord Russell) felt, however, that if anything too formal was insisted upon, Clause 5 would lose its entire value. He could assure noble Lords that the utmost attention would be paid to their suggestions, and the Government would welcome any assistance in making the measure a better Bill.

The Bill was read a second time.

HOUSE OF COMMONS.

Wednesday, Nov. 27th.

Health of Public Aircraft Pilots.

Mr. Lees asked the Under Secretary of State for Air how many seaplanes were employed on the Imperial Airways' route from Genoa to Alexandria; how many pilots were available for this route; what rest period was arranged for these pilots; whether there had been any cases of sickness amongst the pilots during the last few months; and whether the Air Ministry took any steps to assure itself that pilots in public aircraft were in good health before starting on a journey.—Mr. Montague replied: I assume that my hon. friend is referring to the normal service which runs via Genoa. He is no doubt aware that that service has been temporarily suspended. For the normal route from Genoa to Alexandria three flying boats were employed and four pilots were available for the service. They were only engaged in flying duties on three days out of ten, and I understand that there was not an undue amount of sickness among the pilots during the last few months. As regards the last part, under the existing regulations, pilots of public aircraft are required to be medically examined at least every six months for the renewal of their licences, and in order to ensure the maintenance of their efficiency they are also required to be re-examined and pronounced fit before resuming air duties (*a*) whenever they have performed a total of 125 hours flying as pilot within any period of 30 consecutive days since their last medical examination, and (*b*) after illness or accident.

Thursday, Nov. 28th.

Deaths from Silicosis in Sheffield.

Mr. Hoffman asked the Home Secretary the number of deaths from silicosis in Sheffield for the years 1928 and 1929 respectively, and the number of cases in which compensation had been paid under statutory rules and orders during the same period.—Mr. Clynes replied: I have no accurate information in regard to the first part of this question, but it is estimated that the number of deaths from silicosis or silicosis accompanied by tuberculosis was 28 in 1928 and 35 in 1929. Compensation was paid under the Refractories Industries Scheme in 12 cases, including one fatal case, in 1928, and in ten cases, including three fatal cases, in 1929. Under the Metal Grinding Scheme there were 12 cases, including one fatal case, in 1928. Figures for 1929 are not available yet for the metal grinding industries nor for the sandstone and various industries schemes, which only came into force in the early part of this year.

Prison Doctors and Infliction of the Cat.

Mr. Benson asked the Home Secretary the number of cases during the past three years in which, owing to the effect upon the prisoner, the prison doctor had intervened to postpone the completion of the infliction of the cat in order that the prisoner might recover sufficiently to stand the completion of the flogging; and the number of cases in which more than one postponement had been necessary.—Mr. Clynes replied: There has been no such case in the last three years, and from inquiries made it has been ascertained that officers with over 30 years' experience of the prison service have never heard of such cases. If a medical officer stops corporal punishment his intervention is final, and there is no further corporal punishment.

Inspection of Vivisection Experiments.

Mr. Freeman asked the Home Secretary the number of inspectors of vivisection experiments; whether any or all of them were men who had had a medical training; whether he would consider the appointment in future of men known to be primarily interested in the welfare of animals; and whether he would appoint some women inspectors.—Mr. Clynes replied: There are two inspectors, both of whom have had a medical training. There are no vacancies at present and no further appointments are in contemplation. Should a vacancy arise, the candidate with the best qualifications, irrespective of sex, will be appointed.

Women Medical Officers in Prisons.

Mr. Lovat-Fraser asked the Home Secretary whether there were any women medical officers in women's prisons or sections of prisons; and, if not, whether he would consider the desirability of appointing them.—Mr. Clynes replied: There are two women medical officers at Holloway Prison, and there is a woman medical officer at Aylesbury Borstal Institution. At other prisons where the women form only a small proportion of the prisoners, the difficulty hitherto has been that the appointment of a woman medical officer would mean adding to the staff and paying two officers to do work which can be done by one.

Sexual Offences against Young Persons.

Dr. Phillips asked the Home Secretary whether he was now prepared to say what action he proposed to take to put into operation the recommendations of three departmental committees on Sexual Offences against Young Persons, on the Treatment of Young Offenders, and on Metropolitan Police Courts and Juvenile Courts respectively.—Mr. Clynes replied: Various recommendations of these committees not requiring legislation have already been brought to the notice of the courts. Some of the recommendations have already been passed into law, while others have been noted for legislation at a suitable opportunity. As soon as the state of public business permits the Government is anxious to introduce a Bill to amend the Children Act, 1908, and the recommendations of these committees are being taken into consideration in the framing of the Bill. As regards the Committee on Metropolitan Police Courts and Juvenile Courts, its recommendations do not require legislation, and steps have been taken, or are being taken, to give effect to all of them, including the recommendations in regard to the reorganisation of the juvenile courts in London.

Decrease in Overcrowding.

Mr. Simon asked the Minister of Health whether he had evidence as to whether the overcrowding, as revealed in the 1921 census, had in general increased or decreased since that date in the slum areas in different parts of the country.—Mr. Greenwood replied: I have no direct evidence on this subject, but more than a million and a quarter new houses have been completed in England and Wales since the date of the census of 1921, and this number is greatly in excess of normal requirements. It may, therefore, be assumed that overcrowding has in general decreased.

Local Authorities and the Control of Caravans.

Major Owen asked the Minister of Health whether, in view of the difficulties which were being experienced by local authorities with respect to caravans and other similar dwellings and the permanent nature of many of these dwellings, he would introduce legislation granting local authorities more extended powers to deal with such structures.—Brigadier-General Clifton Brown, Mr. Cocks, and Mr. Oswald Lewis asked similar questions.—Mr. Greenwood replied: My attention has been drawn to this matter, and I have received resolutions from a number of local authorities. I am advised that most, at any rate, of the trouble could be met if local authorities exercised more thoroughly and vigorously the powers which they now possess, and I am not satisfied that further legislation is needed. I am always pleased to give local authorities what assistance I can if they consult me on their particular difficulties.

Undulant Fever.

Lieut.-Colonel Fremantle asked the Minister of Health the number of cases of undulant fever in England and Wales during the last five years; if he had any evidence showing whether there was any connexion between that disease and contagious abortion in cattle; and whether any combined research work was being carried out into the subject by his department, the Medical Research Council, and the Ministry of Agriculture.—Mr. Greenwood replied: Undulant fever is not notifiable in this country, and no exact figures of the number of cases which have occurred are available. I understand, however, that 14 cases have been traced as having occurred in England and Wales during the period referred to. An inquiry into this disease has been made by a medical officer of my department, and his report, which has recently been published, contains evidence, mainly from foreign sources, showing that cases of undulant fever in man have been causally related to cattle affected by contagious abortion. The whole subject is receiving careful attention by my department in coöperation with the Medical Research Council and the Ministry of Agriculture and Fisheries.

Price of Graded Milk Licences.

Brigadier-General Clifton Brown asked the Minister of Health whether, in order to encourage the production of cleaner milk, he would reduce the price of licences for Certified and Grade A (T.T.) milk which the producer had now to pay.—Mr. Greenwood replied:—The amount of the licence fees does not exceed the special cost of administering the grading scheme, and higher prices are charged for these milks than for ordinary milk. I am not at present satisfied that there is sufficient justification for a reduction of the fees but I will consider the matter further in consultation with my right honourable friend, the Chancellor of the Exchequer, when opportunity occurs for the general revision of the Special Designations Order.

Artificial Sunlight Treatment.

Dr. Forgan asked the Minister of Health if it was the intention of the Government to extend the facilities for the preventive administration of artificial sunlight to mothers and children; and, if so, what steps he proposed to take to overcome any shortage of medical practitioners who were qualified for such work.—Mr. Greenwood replied: The extension of facilities for this form of treatment is a matter in the first instance for the local authorities. I am not at present aware of any shortage of doctors who have experience of this method of treatment.

Collection of Refuse in Open Dust-carts.

Mr. Day asked the Minister of Health whether his attenion had been drawn to the manner in which rubbish and refuse was still collected in some of the London boroughs in open dust-carts; and if he would consider introducing legislation to abolish open dust-carts not only in London but in all thickly populated areas.—Mr. Greenwood replied: My attention has been drawn to this matter. Legislation has not up to the present been considered to be necessary. Local authorities are increasingly making use of dust-carts with covers, and are encouraged by my Department to do so. So far as London is concerned, I think it will be best to wait until the *Departmental Committee on London Cleansing* have made their report.

Mental Defectives.

Major Glyn asked the Minister of Health how many defectives were being administered under the Mental Deficiency Act and what was the cost to the local authorities and to the Exchequer; what was the cost of the institutions directly under the administration of the Board of Control, and to what extent local authorities contributed; and how many defectives there were under treatment at these institutions.—Mr. Greenwood replied: The total number of defectives maintained in institutions or under guardianship at the joint charge of local authorities and the Exchequer on Jan. 1st, 1929, was 20,859, and there were 19,606 under supervision. The total cost for the year ended on March 31st, 1929, was £1,216,820. Of this expenditure £607,301 is borne by local authorities and £609,519 by the Exchequer. In addition a relatively small number of defectives was maintained in institutions or under guardianship at the sole charge of local authorities. Particulars of the numbers and cost are not available. The total cost to the Board of Control of State institutions directly under their administration during the year ended on March 31st, 1929, was £45,045, towards which £1838 was contributed by local authorities or relatives of patients. The number of defectives under treatment at these institutions on Jan. 1st, 1929, was 785.

MONDAY, DEC. 2ND.

Grants for Surgical Appliances.

Mr. Day asked the Minister of Pensions the number of cases during the previous 12 months in which he was able to make grants for surgical appliances out of the voluntary funds at his disposal.—Mr. F. O. Roberts replied: During the 12 months ended Oct. 31st, 1929, 81 grants were made from the voluntary fund for the purchase of surgical appliances.

Malaria in Bengal.

Commander Bellairs asked the Secretary for India whether his attention had been drawn to the increase of preventible malaria in Bengal and the recent report of Sir Malcolm Watson to the Ross Institute for an inquiry; whether he would follow the precedent of Mr. Joseph Chamberlain, who instituted an inquiry that led to the stamping out of Mediterranean fever; and whether he would immediately promote liaison work with British Guiana where a similar problem with part East Indian population had been successfully dealt with.—Mr. Wedgwood Benn replied: So far as I am aware there has been no increase in malaria in Bengal in recent years. I understand that Sir Malcolm Watson's suggestion was that an inquiry should be made as to whether the embankments of the Ganges Delta produce conditions favourable to malaria; and, if so, whether a remedy could be found. This matter is now engaging the attention of the Government of Bengal. I may add that a chair of malariology will be established in the new Rockefeller Institute in Calcutta.

Lieut.-Colonel Fremantle: Is it not a fact that no policy has yet been given out that would really reduce malaria; that it requires a great deal more inquiry; and would it not be a good thing to institute a Government inquiry with the different departments concerned with India and the Colonies generally?

Mr. Wedgwood Benn: That is a much wider question. I have stated what steps are being taken in India.

Medical Appointments in India.

Major Graham Pole asked the Secretary for India what action the Government of India intended to take in view of the rejection by the Indian legislative assembly of the proposal of the Government to appoint a European officer of the Indian Medical Service as a whole-time commissioner of medical qualifications and standards; and whether the creation of this post was proposed as an alternative to the creation of a Government commission on medical qualifications and standards or as an expedient pending the setting up of such permanent machinery.—Mr. Wedgwood Benn replied: The demand for a grant for the expenses of this appointment was not rejected by the Legislative Assembly as the House was adjourned before the termination of the debate on it. The Government of India are consulting the provincial governments as to the measures to be adopted to meet the situation and to secure the continued recognition of Indian medical degrees. The creation of the post was proposed as a temporary measure pending the establishment, by legislative enactment, of an all-India Medical Council.

WEDNESDAY, DEC. 4TH.

River Pollution on Dartmoor.

Major Hills asked the Minister of Health whether his attention had been called to the danger of pollution of the Dartmoor rivers by opening china-clay works on Dartmoor; and whether he would consider, without interfering with what might be a valuable industrial enterprise, taking measures against pollution of those rivers.—Miss Lawrence replied: The answer to the first part of the question is in the negative. As regards the second part, the prevention of pollution is a matter for the local authorities, and no doubt this particular case will engage their attention.

School Children and the Schick Test.

Mr. Freeman asked the Minister of Health by what authority local authorities imposed the Schick test against diphtheria on school children; what evidence was there that it prevented diphtheria; what instructions were issued to the parents concerning the matter; how many children were so operated on in 1928 and how many times each; and what was the cost per head of each operation.—Miss Lawrence replied: Local authorities do not "impose" this test on school children. Parents are invited to have their children tested, and, if desired, immunised. The procedure is entirely voluntary. Local authorities are empowered to act for this purpose with the *sanction of my Department* under Section 133 of the Public Health Act, 1875, or Section 77 of the Public Health (London) Act, 1891. Advice is given to parents by the local authority, but no instructions are issued. As regards the second part of the question, my right hon. friend is advised that there is abundant evidence that the practice of active immunisation, applied to persons who have been shown by the Schick test to be susceptible to diphtheria, protects such persons against the disease. My right hon. friend has no information in regard to the last two parts of the question.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdrs. O. J. M. Kerrigan to *Virid*, to *Comus*, and to *President* ; T. Gwynne-Jones to *Fisgard* ; C. J. Aveling to *Britannia* ; G. H. Courtier to *President* ; and E. Kennedy to *Resolution*.

Surg. Lt.-Comdr. D. H. Kernohan to *Comus*.

Surg. Lt.-Comdrs. (D.) : J. L. Edwards to *Pembroke*, for R.N. Barracks, Chatham ; H. J. Luck to *Fisgard* ; W. E. A. Sampson to *Flora*, for R.N. Hospital, Cape of Good Hope ; and D. Barker to *Effingham II*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub-Lts. to be Surg. Lts. : G. O. Barber and E. C. W. Maxwell.

Proby. Surg. Lt. W. T. R. Chapman to be Surg. Lt.

ARMY MEDICAL SERVICES.

Lt.-Col. W. P. MacArthur, R.A.M.C., Professor of Tropical Medicine, Royal Army Medical College, to be Consulting Physician to the British Army in succession to Col. J. C. Kennedy, is proceeding to India on duty.

ROYAL ARMY MEDICAL CORPS.

Maj. J. Boyd relinquishes his temp. commn. and retains the rank of Maj.

Maj. A. Irvine-Fortescue is restd. to the estabt.

Lt. (on prob.) G. F. Harrison, from the secd. list, is rest. to the estabt.

Lt. (on prob.) E. G. C. Darke is secd. under the provisions of Art. 205, Royal Warrant for Pay and Promotion, 1926.

The undermentioned Lts. (on prob.) are confirmed in their rank : E. M. Hennessy and J. M. Ryan.

REGULAR ARMY RESERVE OF OFFICERS.

The undermentioned having attained the age limit of liability to recall, cease to belong to the Res. of Off. : Col. F. F. Carroll, late R.A.M.C., and Maj. J. B. Clarke.

TERRITORIAL ARMY.

Lt. J. N. C. Ford, late R.G.A. (Spec. Res.), to be Lt.

ROYAL AIR FORCE.

J. W. H. Steil is granted a temporary commn. as a Flight Lt. (Hon. Squadron Leader).

Flying Officer J. C. Neely is promoted to the rank of Flight Lt.

Flight Lt. R. A. W. Kerr is transferred to the Reserve, Class DII.

DEATHS IN THE SERVICES.

Surg. Lt.-Comdr. Gilbert Maliso Graham, R.N. retd., whose death after a long illness was recently announced, entered the Navy as a surgeon in 1914, and was subsequently appointed to H.M. *Emperor of India*, the Flagship of Rear-Admiral A. L. Duff in the Grand Fleet. Two years later he was appointed to the Naval Hospital at Malta, where he served till after the Armistice. In 1920 he joined H.M.S. *Truro*, and during his service with the Mine-sweeping Flotilla was promoted Surg. Lt.-Comdr. He retired in 1922.

POPLAR HOSPITAL FOR ACCIDENTS.—Hitherto this institution has been almost entirely supported locally. The Port of London Authority—which provides a fast ambulance for the transport of casualties—shipping firms, factory employees and patients, all contributed to the cost of maintenance, which amounts to £22,000 a year. The hospital was founded in 1855 to deal with dock accidents, was rebuilt in 1891, and has since then been six times enlarged, but the growth of the docks and shipping business and the increase in heavy motor traffic are such that the hospital has become seriously inadequate. One fourth of the accident cases are children, and recently in one week-end eight cases of fractured skull were admitted. It is stated that the pressure upon the out-patient department is so severe that patients have sometimes to wait four or five hours for their turn ; 52,000 cases are dealt with annually. The X ray apparatus has been in use for 20 years and can deal only with ordinary fractures. It is now proposed to spend £30,000 on improvements, which will include an adequate X ray installation ; and an appeal is about to be made for the money.

Medical News.

UNIVERSITY OF OXFORD : *Radcliffe Travelling Fellowship*.—An examination for a Fellowship of the annual value of £300, tenable for two years, will begin on Feb. 11th.

Candidates must have passed all the examinations required for the B.A. and B.M., degrees and must not have exceeded four years from the time of passing the last examination required for the latter. The successful candidate must devote himself during his tenure of the Fellowship to the study of medical science, principally abroad. The examination papers will be set in physiology, pathology, and preventive medicine, and a subject will be proposed for an essay. There will also be a practical examination in pathology. Candidates may offer in addition a special branch of either medicine or surgery.

Application must be made to the Regius Professor of Medicine before Jan. 20th, 1930.

UNIVERSITY OF CAMBRIDGE.—On Nov. 30th the following degrees were conferred :—

M.D.—R. J. Lythgoe and H. W. Eddison.

M.B. & B.Chir.—M. D. Nosworthy, J. M. Graham, and E. A. Trim.

M.B.—Frank Goldby and J. O. W. Bland.

UNIVERSITY OF LONDON.—At recent examinations the following candidates were approved :—

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

With Special Knowledge of Psychiatry.—F. T. Thorpe and Mary E. Tyars.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates were approved :—

MASTER OF MIDWIFERY.

Lily A. Baker, N. R. Mucadam, W. G. Richards, and G. C. Soutter.

ROSS AWARD FUND.—In supplement to his letter on p. 1171 of our last issue Sir James Barr informs us that the Government of India have contributed the sum of £2000 to this Fund. The gift brings the total to £12,082.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The council of this Institute has appointed Prof. William H. Park, Director of the Bureau of Laboratories of the New York Health Department, to be Harben Lecturer for 1930, and Dame Louise McIlroy, Professor of Obstetrics and Gynæcology in the University of London, to be Harben Lecturer for 1931. The Smith Award for 1930 has been given to Dr. H. R. Kenwood, Emeritus Professor of Hygiene in the University of London. This award is made every third year to a medical officer of health "who is recognised as having done the most noteworthy work in the discharge of his official duties."

ORTHOPÆDIC HOSPITALS.—The annual report of the Shropshire Orthopædic Hospital and Agnes Hunt Surgical Home, Oswestry, records a slight falling-off in the number of child patients in consequence of the opening of children's orthopædic hospitals in different parts of the country ; nevertheless 500 adults and 480 children were treated. At the end of the year Dame Agnes Hunt resigned her post as honorary superintendent. Of the income of £48,000, £41,243 was contributed by, or on behalf of, patients. An adjoining property has been purchased for use as a training college. In the school for physically defective children the junior classes are given a good grounding in the buying and selling of household goods, in specially constructed shops, with cardboard coins. The massage department gave over 30,000 treatments. During 1928 the admissions to Wingfield Orthopædic Hospital, near Oxford, numbered 338, of whom 101 were children : in addition, 95 private patients were treated ; and over 18,000 out-patients were attended at the various clinics. The work increased considerably during the year, owing to increased publicity. Rebuilding is fast becoming an urgent necessity. The report of the North Staffordshire Cripples' Aid Society for the year ending March 31st last emphasises the need for a more adequate out-patient clinic and after-care centre. The special orthopædic work of the hospital is still being done, and in the coach-house and stables which were improvised for the purpose in 1918, and the work is greatly hampered by the insufficient number of beds. The orthopædic hospitals, it is pointed out, still have a nursing problem ; since there is no standard, each hospital has to make the most suitable arrangements for itself.

WALSALL GENERAL HOSPITAL.—"The sheer impossibility of dealing adequately with an incessant stream of accidents" has, the annual report records, led to the erection of a new casualty department, opened in March last. There were 17,940 attendances in the orthopædic department and 7635 treatments and exposures in the X ray department.

BRISTOL HOSPITAL FOR CHILDREN AND WOMEN.—This hospital is to be enlarged at a cost of £90,000. The present building was opened in 1886, and many extensions and improvements have since been made. The proposed scheme of reconstruction includes the addition of an extra storey to two of the blocks provided with sunlight balconies for open-air treatment.

ENLARGEMENT OF WORTHING HOSPITAL.—Two new wards, forming a further instalment of the enlargement of this institution, were opened last week by Mrs. Arthur Lloyd, who has contributed £8500 towards the cost of the work. Since the extensions began in 1926 the number of beds has been increased from 46 to 78, and various improvements have been made at a cost of £12,000. The new wards (for women) contain 20 beds in place of the former nine, and new X ray and massage departments have been added.

ST. BARTHOLOMEW'S HOSPITAL, ROCHESTER.—The average cost of the 1858 in-patients admitted last year was £8 12*s.* 7*d.*; the out-patients cost 6*s.* 6*d.* each. An extension fund of £80,000 is being collected, and various extensions and improvements are in progress. A new pathological department has been provided, and there are to be new out-patient and casualty departments. Paying patients are now received at a minimum charge of three guineas a week, exclusive of medical and surgical fees.

DENTAL HOSPITAL OF IRELAND.—The annual report shows that in the twelve months under review over 18,000 patients attended, an increase of nearly 1000. Only 16 teeth were extracted without an anæsthetic. The Dublin schools sent 1075 children for treatment. Subscriptions amounted to no more than £381, "an amount not very creditable to a large city like Dublin." The Dental Branch of the United Kingdom has made a grant of £900. There are 50 students.

MANCHESTER STUDENTS' RAG.—A proposal has been made that the entire proceeds of the Annual Rag on Shrove Tuesday next year should be given for the purpose of building a new wing to the Cancer Hospital. After a full discussion the students of the University decided to leave the allocation of the funds to the Hospital Council, but have ear-marked £1000 each for the Christie Cancer Hospital, the Dental Hospital, and the North Manchester Maternity Hospital.

UNIVERSITY OF LIVERPOOL.—At the yearly meeting of the University Court on Nov. 29th the Vice-Chancellor announced that within the last six months the University had received something like £40,000 for the endowment of research—the greater part of it to be devoted to special fields. Upwards of £20,000 was to go for research in cancer and tuberculosis, another £10,000 to be devoted to research in any field of University study, and another £10,000 by various subscribers for the endowment of research in animal pathology in the severe diseases which from time to time decimated our herds of cattle.

DONATIONS AND BEQUESTS.—Mr. Alfred Hayes, of Hawkestone, Western Park, Leicester, left £2000 to the Leicester Infirmary and £1000 to the Home for Incurables, Leamington, Warwickshire.—Mr. Anthony Brown, of Pond End, Knaresborough, Yorks, left practically the whole of his estate to charitable and philanthropic objects. Amongst the bequests are £2000 to Harrogate General Infirmary to endow two beds in his name, £1000 to Royal Bath Hospital, Harrogate, and £1000 to National Institute for the Blind. The residue of the property is left between Newcastle General Infirmary, Harrogate Infirmary, and Leeds General Infirmary.—Miss Mary Ann Shelton, of Pinchbeck-street, Spalding, in addition to other bequests, left £2000 subject to a life trust equally between the London Hospital and the Cancer Hospital, Fulham-road; £1000 each to the London Hospital, Whitechapel-road, and the Cancer Hospital; £500 to the Royal Society for the Prevention of Cruelty to Animals.—Mr. John Cross, of South-drive, Harrogate, left, besides other bequests, £1000 to the York County Hospital; £200 to the Harrogate Infirmary; £100 each to the Yorkshire Home for Incurables, Harrogate, and the Rawson Convalescent Home, Harrogate.

STOCKPORT INFIRMARY.—The work of this hospital has for some time past been impeded by lack of room. Various extensions have been made, but it is still impossible to cope with the demands, and it has therefore been decided to build an entirely new hospital. A site of 14 acres has been purchased, upon which will be erected a building to hold 400 beds. The work, which will need five years for its completion, is estimated to cost £250,000. There are at present 130 beds.

BRADFORD MUNICIPAL HOSPITAL.—The report for 1928 by Mr. B. Holroyd Slater, the medical superintendent, shows that since 1920, the first year of municipal control, the number of patients admitted has increased by 88 per cent.—7176 as compared with 3804; the number of births by 814 per cent., and the number of operations by 418 per cent. Puerperal sepsis provided the largest number of cases (63) of infectious disease. There were 11 maternal deaths, 951 live births and 60 stillbirths.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Dec. 9th.—5 P.M., WAR. Paper:—Surgeon-Commander A. E. Malone, R.N.: *Some Remarks on the Evolution of Naval Hygiene.*

TUESDAY.—5 P.M., THERAPEUTICS AND PHARMACOLOGY. Communications and discussions: Dr. J. W. Trevan, Dr. T. Izod Bennett, Dr. D. T. Davies, Dr. L. E. H. Whitby, and others: Phenylhydrazine in the Treatment of Polycythæmia. Dr. Bernard Schlesinger, Dr. F. J. Poynton, and others: Nirvanol in the Treatment of Chorea.—8.30 P.M., PSYCHIATRY. DISEASE IN CHILDREN. (Members of the Child Guidance Council will also take part in the following discussion.) Special Discussion on: The Difficult Child. Speakers: Dr. Bernard Hart, Dr. Emanuel Miller, Psychiatry. Dr. Hector Cameron, Section for the Study of Disease in Children. Dr. W. Moodie, Miss Fildes, Child Guidance Council.

WEDNESDAY.—5.30 P.M., SURGERY: SUBSECTION OF PROCTOLOGY. Pathological Meeting preceded by a Discussion on Complications of Operations for Piles, to be opened by Mr. Cecil Rowntree (President of the Subsection). Cases and Specimens:—Mr Cecil A. Joll: Combined Abdomino-perineal Excision of the Rectum and Wertheim's Hysterectomy for Carcinoma of the Recto-vaginal Septum. Mr. Cecil A Joll: Abdomino-perineal Excision of Rectum for Endometrioma. Dr. H. J. B. Fry: Multiple Papillomatosis of the Colon with Double Primary Carcinoma of the Rectum. Dr. H. J. B. Fry: Diverticulitis with Carcinoma of the Rectum. Dr. H. J. B. Fry: Sacro-coccygeal Chordoma Simulating a Colloid Carcinoma of the Rectum. Dr. H. J. B. Fry: Colloid Carcinoma of the Rectum in a Young Subject, with Metastases in the Skull. Dr. H. J. B. Fry: Papilloma of the Rectum Removed by Perineal Excision. Dr. H. J. B. Fry: Secondary Melanotic Sarcoma of the Colon. Dr. Graham Hodgson: Cases of Diverticulitis.

THURSDAY.—8.30 P.M., NEUROLOGY. Short Papers:—Dr. James Collier: Ocular Paralysis in Diabetes. Dr. Macdonald Critchley: The Syndrome of the Anterior Cerebral Artery.

FRIDAY.—5.30 P.M., CLINICAL. (Cases at 4.30 P.M.) Dr. C. Worster-Drought: A Case of Dystrophia Myotonica. Dr. Terence East: Case of Polycythæmia Vera. Mr. Cecil P. G. Wakeley: Case of Large Chondroma of the First Rib in a Child. Dr. Harold Cookson: Specimen, Rheumatic Carditis, Pan-valvulitis. Dr. F. Parkes Weber: Combined Degeneration of the Spinal Cord, without the Blood Picture of Pernicious Anæmia. Dr. H. V. Morlock: Case of Familial Acholuric Jaundice. Mr. Harold Edwards: Severe Deformity following Burns. Dr. Dorothy Hare: Case of Congenital Morbus Cordis with Ascites. Dr. E. Stolkind: Case of Abnormality of the Gall-bladder. Dr. Norman Hill: Case of Amyotonia Congenita. 5 P.M., OPHTHALMOLOGY. Clinical Meeting at the Royal London Ophthalmic Hospital, City-road, E.C.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Dec. 9th.—8.30 P.M., Discussion on: The Treatment of Head Injuries. To be introduced by Mr. Wilfred Trotter.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THURSDAY, Dec. 12th.—8.15 P.M., preceded by a Demonstration at 7.45 P.M. (at 11, Chandos-street, Cavendish-square), Prof. Warrington Yorke: Blackwater Fever.

BIOCHEMICAL SOCIETY.

Friday, Dec. 13th.—3 P.M. (in St. Bartholomew's Hospital E.C.). Communications:—H. E. Archer and G. A. Harrison: The Effect of Reaction on the Heat Test for Bence-Jones' Proteinuria. W. H. Hurtley: Notes on the Determination of Iodine in Blood, &c. K. V. Thimann: The Precipitation of the Basic Amino-acids of Proteins by Phosphotungstic Acid. M. J. Rowlands and B. Wilkinson: Vitamin Content of Grass Seeds in Relationship to Manures. A. G. Norman: The Biological Decomposition of Plant Materials. D. R. P. Murray and C. G. King: The Stereochemical Specificity of Esterases. H. Chick and M. H. Roscoe: Stability to Heat of Vitamin B2 (Anti-dermatitis, Anti-pellagra). F. K. Herbert and M. C. Bourne: The Non-glucose Reducing Substances of Blood with Special Reference to Glutathione. B. W. Town: Isolation of Isoleucine from Gliadin. H. G. Reeves and E. T. Renborn: Some Properties of Dihydroxyacetone. J. M. Gulland and R. A. Peters: Observations on the Reducing Substances in Avian Blood. G. Graham: The Presence of Homogentisic Acid in the Blood of Patients with Alkaptonuria.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

Medical Society of London, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Lecture by Mr. John O'Malley: Inflammations of the External Ear. No fee.—National Hospital for Diseases of the Heart, Westmoreland-street, W. Wed., 6 P.M., Demonstration by Dr. T. F. Cotton. No fee.—South London Hospital for Women, 103, South Side, S.W. Wed., 2.30 P.M., Demonstration by Miss Huxley (General). Open to women graduates only. No fee.—Infants Hospital, Vincent-square, S.W., Afternoon Course, second week.—London Temperance Hospital, Hampstead-road, N.W., Practitioners' Course, second week.—Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE. Hammersmith, W.

Monday, Dec. 9th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Wards.

Tuesday.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw, Medical Out-patients. 2.30 P.M., Sir Henry Simson: Gynæcological Operations.

Wednesday.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. Dr. Scott Pinchin: Medical Out-patients.

Thursday.—11.30 A.M., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

Friday.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Shaw: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.

Saturday.—9 A.M., Mr. Vlasto: Throat, Nose and Ear Operations. 9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Children's Department.

Daily, 10 A.M. to 5 P.M., Medical, Surgical and Special Out-patients, Operations, Ward Visits. Anæsthetic Courses.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday, Dec. 9th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

Tuesday.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

Wednesday.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

Thursday.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics. Operations.

Friday.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations. 4.30 P.M.: Demonstration on Practical Neurology by Dr. L. R. Yealland.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Monday, Dec. 9th.—5 P.M., Mr. J. C. Dawes, M.I.Mech.E.: Disposal of Refuse.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.

Thursday, Dec. 12th.—9 P.M., Dr. T. East: The Electrocardiograph and its Use: A Practical Demonstration.

SOUTH-WEST LONDON POST-GRADUATE SOCIETY, St. James's Hospital, Ouseley-road, Balham, S.W.

Wednesday, Dec. 11th.—4 P.M., Mr. E. T. C. Milligan: Modern Methods of Diagnosis of Rectal Diseases.

ROYAL ANTHROPOLOGICAL INSTITUTE.

Wednesday, Dec. 11th.—5.30 P.M. (in the Polytechnic Hall Extension, Great Titchfield-street, W.), Prof. F. G. Parsons: The Anthropological History of the Modern Englishman.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

Friday, Dec. 13th.—4 P.M., Dr. Dan McKenzie: Early Mastoid Operations.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

Tuesday, Dec. 10th.—5 P.M., Dr. S. E. Dore: Erythemato-squamous Eruptions.

Thursday.—5 P.M., Dr. W. N. Goldsmith: Pigmentation of the Skin.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.

Wednesday, Dec. 11th.—4.15 P.M., Clinical Meeting. Cases will be demonstrated in the wards. Tea at 4 P.M. Medical Practitioners invited.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

Wednesday, Dec. 11th.—4 P.M., Prof. Winifred Cullis: Speed as a Psycho-Physiological Factor in the Life of To-day.

PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, W.

Friday, Dec. 13th.—6 P.M. (at the Medical Society of London, 11, Chandos-street, W.). Dr. R. O. Moon: The History of Medicine and the Part Played by the British Race.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, Dec. 10th.—4.15 P.M., Mr. W. H. Hey: Post-operative Embolism.

ANCOATS HOSPITAL, Mill-street, Manchester.

Thursday, Dec. 12th.—4.15 P.M., Dr. E. W. Twining: X Ray Treatment of Hyperthyroidism and Blood Diseases.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

Friday, Dec. 13th.—3.30 P.M., Mr. G. Simpson: Cystoscopy.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

Wednesday, Dec. 11th.—4.15 P.M. (in the Victoria Infirmary), Dr. A. McLachlan: Skin Cases.

Appointments.

Galloway, R. M., M.D. Edin., D.P.H., has been appointed Medical Officer of Health, Dewsbury.

Mackenzie, J. J. R., M.B., Ch.B. Edin., Certifying Surgeon under the Factory and Workshop Acts at King's Cliffe, Northampton.

Massey, A., M.D. Leeds, D.P.H., Medical Officer of Health for Coventry.

Bolingbroke Hospital: Carew-Shaw, E., M.R.C.S, L.R.C.P. Lond., Clinical Assistant Ear, Nose and Throat Department; Walker, G. B. W., M.B., B.Chir. Camb., F.R.C.S., Resident Medical Officer.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital, 91, Finchley-road, N.W.—Hon. Radiologist. Hon. Surg. Reg. Also Two H.S.'s. Each at rate of £150.

Barnet, Herts, Wellhouse Hospital.—Obst. Res. and Asst. M.O. At rate of £250.

Barnsley, Beckett Hospital and Dispensary.—H.P. £140.

Bolingbroke Hospital, Wandsworth Common, S.W.—Hon. Anæsthetist.

Brighton County Borough Infectious Disease Hospital, &c.—Res. M.O. £350.

Brighton, New Sussex Hospital for Women and Children.—Radiologist.

Bristol General Hospital.—Surgeon, Asst. S., Asst. P., Clin. Assts., Dental S. Also Pathologist. All Honorary.

Bristol Royal Infirmary.—H.S. to Ear, Nose and Throat Dept. At rate of £60.

Burnley, Victoria Hospital.—H.S. At rate of £125.

Cairo, Egyptian University, Faculty of Medicine.—Two Surgical Tutors. £E35 monthly.

Canterbury, Kent and Canterbury Hospital.—H.P. £125.

Cardiff, Prince of Wales' Hospital.—Res. Surg. £350.

Carlisle, Cumberland Infirmary.—Pathologist and Bacteriologist. £900.

Chelsea Hospital for Women, Arthur-street, S.W.—Pathologist. £40.

Chester, Wrenbury Hall Tuberculosis Training Colony.—Res. H.P. £250.

Dorchester, Dorset Mental Hospital, Herrison.—Jun. Asst. M.O. £300.

Dreadnought Hospital, Greenwich.—Med. Supt. £300.

Eastbourne, Princess Alice Memorial Hospital.—Jun. H.S. At rate of £100.

Evelina Hospital for Children Southwark, S.E.—H.S. At rate of £120.

Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £250. Also Hon. Asst. Phys.

Greenock Royal Infirmary.—Two H.S.'s. Each £100.

Grocers' Company, Grocers' Hall, E.C.—Research Scholarships. £300.
Guildford, Royal Surrey County Hospital.—H.S. £150.
Hampshire County Council.—Asst. County M.O. £600.
Hove Hospital, Sackville-road.—Res. M.O. £150.
Huddersfield Royal Infirmary.—Res. Surg. O. £220.
Hull Royal Infirmary.—Second H.S. At rate of £160.
Italian Hospital, Queen-square, W.C.—Two Hon. Surgeons.
Leamington Spa, Warneford General Hospital.—Res. H.S. £165.
Leeds Jewish Herzl-Moser Hospital.—Res. M.O. £100.
Liverpool Hahnemann Hospital.—H.S. At rate of £100. Also Hon. Path. £25.
Liverpool Sanatorium, Delamere Forest, Frodsham.—Asst. Med. Supt. £250.
London Lock Hospital, Dean-street and Harrow-road, W.—Second Anæsthetist. 1 guinea each attendance.
London University.—Geoffrey Duveen Travelling Studentship. £450.
Manchester Ancoats Hospital.—Asst. Pathologist. Also Med. Reg. and Surg. Reg. Each £100.
Manchester, Baguley Sanatorium.—Sen. Asst. M.O. £500.
Manchester, Salford Royal Hospital.—Res. Surg. O. £200. Also two Res. H.S.'s to special departments. Each at rate of £125.
Metropolitan Hospital, Kingsland-road, E.—Asst. S. Also Two Anæsthetists.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Nuneaton Borough.—Asst. M.O.H. £600.
Rochester, St. Bartholomew's Hospital.—Third Res. M.O. At rate of £175.
Royal London Ophthalmic Hospital, City-road, E.C.—Asst. Surgeon.
Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.
Ryde, Royal Isle of Wight County Hospital.—Res. H.S. £180.
St. Leonards-on-Sea, Buchanan Hospital.—Sen. and Jun. H.S.'s. £175 and £125 respectively.
Salisbury General Infirmary.—Two H.S.'s.
Scotland Dept. of Health, Bacteriology and Medical Statistics.—M.O.'s. £600.
Sheffield Royal Hospital.—Res. Anæsthetist. At rate of £80.
Sheffield Royal Infirmary.—H.P., H.S., Ophth. H.S., Asst. Ophth. H.S. Also Asst. Cas. O. Each at rate of £80.
Stafford, Staffordshire General Infirmary.—H.S. and H.P. At rate of £200 and £150 respectively.
Westminster Hospital, Broad Sanctuary, S.W.—Asst. Pathologist. £250.
Wigan Infirmary.—Third H.S. £150.
Winchester, Royal Hampshire County Hospital.—Hon. Clin. Asst. for Ophth. Out-Patient Dept. Also Sen. Res. M.O. £200. H.S. £150.
Windsor, King Edward VII. Hospital.—Two H.S.'s. Each £100.
The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Windermere (Westmorland) and Wirksworth (Derby).

Births, Marriages, and Deaths.

BIRTHS.

ATKINSON.—On Nov. 28th, at Grosvenor-street, W., the wife of Dr. C. Hewitt Atkinson, of a son.

BELFRAGE.—On Nov. 30th, at 15, Somers-place, W.2, to Judith, wife of Dr. Douglas Belfrage—a son.

BROWNING.—On Nov. 25th, at Courtfield-gardens, the wife of Basil Browning, M.D., of a son.

JACOBS.—On Nov. 30th, at Maida Vale-mansions, W., to Dr. Elizabeth Jacobs, wife of Dr. L. Jacobs, of a daughter.

ROXBURGH.—On Nov. 26th, at Redington-road, Hampstead, the wife of A. C. Roxburgh, M.D., F.R.C.P., of a son.

SWAINE.—On Nov. 28th, at Beaumont-street, W., the wife of Dr. R. O. Swaine, Bedford House, Bognor, of a daughter.

MARRIAGES.

FERGUS—SMITH.—On Nov. 30th, Andrew Naismith Fergus, M.B., Ch.B., to Jean Elizabeth, elder daughter of Gilbert Smith, M.D., F.R.C.S., and Mrs. Smith, of Hindhead.

O'FLYNN—LEONARD.—On Nov. 20th, at Corpus Christi Church, London, by the Rev. Father E. O'Flynn, Surgeon-Commander J. A. O'Flynn, R.N., to Lynda Avis Lilian Leonard.

DEATHS.

BURKITT.—On Nov. 23rd, at Warneford House, Ravenstone, Leicestershire, after four days' illness, John Colley Smyth Burkitt, M.D.

BYRON.—On Nov. 25th, at "Bellgrove," Gunterstone-road, West Kensington, London, John Lean Byron, L.D.S. R.C.S. Edin.

COCKBURN.—On Nov. 26th, the Hon. Sir John Alex. Cockburn, K.C.M.G., M.D., aged 79.

DAVIES.—On Nov. 24th, Dr. Arthur Templer Davies, aged 71.

DEWAR.—On Nov. 27th, at Edinburgh, Thomas Finlayson Dewar, C.B., M.D., D.Sc., Department of Health for Scotland, aged 63.

MONTGOMERY.—On Nov. 28th, at Roebuck Park, Dundrum, Co. Dublin, Edward Hugh Montgomery, M.D., of Careysville, Fermoy, Co. Cork, aged 60.

SLOGGETT.—On Nov. 27th, suddenly, Lieut.-General Sir Arthur Sloggett, K.C.M.G., K.C.V.O.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE MECCA PILGRIMAGE, 1929.

A DOCTOR standing on the banks of the Suez Canal near Ismailia in June, 1929, saw a ship approaching from the south with a marked list to port. When she drew abreast of the watcher she proved to be a pilgrim ship; the afternoon being hot, the travellers had all crowded to the port side to catch what little wind was stirring. Their numbers were so great that they appeared to cover all the deck space, while the ship was unable to right herself from the list produced by their weight. It is hard to imagine the conditions on a ship so grossly overcrowded, especially when oriental standards of cleanliness are taken into consideration; moreover, the passengers generally prepare their own food, and latrine accommodation is none too plentiful on pilgrim ships.

The Egyptian Government has been making a determined effort this year to provide better conditions for pilgrims visiting Hedjaz. The "*Khedivial Mail Line*" received the concession for the transport of pilgrims, and the results of examination of their boats by the Egyptian authorities appears to have been satisfactory. The largest of these was authorised to take 1505 pilgrims and the smallest 742. The Egyptian authorities advise, however, that 1500 should be the highest number ever carried in future. They cite as an example of overcrowding the case of the *Plata*, a boat of another line, which carried 2000 passengers and three medical officers. Aboard this ship seven persons died between Djeddah and Tor; 11 were in hospital on arrival, four of whom were moribund; 51 were sent into hospital at Tor, of whom nine died. It is thought that the ship was short of provisions as a result of carrying a consignment *of strange pilgrims before returning to pick up those* for whom it had been chartered, and it is suggested that ships should not be authorised for such usage in future. The conditions on another ship, the *Riad*, were found to be extremely unsatisfactory; there was accommodation for only 308 pilgrims but 431 were taken; there was a lifeboat capacity only for 90 persons; washing and sanitary arrangements were hopelessly insufficient; the wireless apparatus consisted of a receiver only, and there was no operator on board. This ship was suspended from further transport of pilgrims by the Director of the Quarantine at Tor.

Attempts are now being made to vaccinate all pilgrims and to inoculate them against cholera before they reach Hedjaz. This year nearly all the pilgrims from the north received both forms of protection, as did those from the south who passed the island of Kamaran. Pilgrims from South and East Africa and from Yemen, Assyt, and Hadramout arrive in small groups, not by pilgrim ships, and probably receive neither vaccination nor inoculation. The problem of suitable protective measures is difficult to solve in view of the large numbers involved; this year it is estimated that 120,000 persons were present on the plains of Arafat on the first day of the feast. Statistics from Hedjaz are naturally difficult to obtain; the deaths from small-pox and dysentery show an increase this year over those recorded in 1928, but this may be because they have been more carefully observed. The water-supply to the pilgrims, which has sometimes been insufficient at Hedjaz, was plentiful this year as a result of a rainy winter. Condensers are available at Djeddah and Yambo.

There can be no doubt that the quarantine arrangements at Tor, which include a hospital and an efficient medical and nursing staff, do much to prevent epidemics following the return of pilgrims to their homes. This year 29,358 persons passed through the settlement; only 43 deaths are recorded and autopsies were performed in all cases; six of these died of dysentery and two of typhoid; none of typhus, small-pox, or cholera. The stools of all cases receiving medical treatment were examined for the cholera vibrion. The danger to pilgrims from infected persons joining the pilgrimage from areas in which epidemics are in progress is considered in the report of the Conseil Maritime *et Quarantenaire d'Egypte for 1929. Epidemics of small-pox* occurred in Iraq and the Sudan between October, 1928, and April, 1929; there was a small epidemic of plague in Upper Egypt and a larger one (101 cases) in Morocco. There were 953 cases of typhus in Egypt and 32 in Palestine during the same period.

The yearly pilgrimage will remain a danger to all the countries from which pilgrims are drawn as long as the conditions of transport and accommodation remain as scanty and unhygienic as at present. Efficient reorganisation of the pilgrimage in every direction is needed and should be facilitated by the governments of the large number of countries involved.

ENLARGEMENT OF A DUBLIN HOSPITAL.

Jervis-street Hospital is the oldest of the Dublin voluntary hospitals, having entered its third century some 11 years ago. It was originally founded in Cook-street by six surgeons, and its rapid success caused its removal two years later to the Inns Quay, where the Four Courts now stand. When the site was wanted for the erection of the Four Courts nearly 60 years later, the governors bought the town house of the Earl of Charlemont in Jervis-street, and occupied it from 1786 to 1803, when it was replaced by a more commodious building. This in turn was replaced in 1887 by the present hospital. Various additions have since been made, of which the most important were a new out-patient department in 1910, and a new theatre block in 1919. Last week the Archbishop of Dublin opened a new wing, which contains a chapel, and improved accommodation for the Sisters of Mercy, who control the nursing, and for the resident staff. The hospital is now very thoroughly equipped in accordance with modern ideas. It is situated in the heart of the city, surrounded by many industrial works and crowded tenement areas. It deals, therefore, both with an exceptionally large number of accidents and with much sickness among the very poor. It is gratifying that the governors and medical staff are actuated by a progressing spirit.

MEDICAL PROGRESS IN CEYLON.

IN the annual general report for 1928, the section devoted to public health begins with the gratifying assurance that "there are few countries in the world in which medical aid is more generously distributed by the State than Ceylon." In proof of this it is mentioned that there are 101 government hospitals and asylums with provision for 10,250 beds. In Colombo, the capital, are situated a general hospital with 850 beds, an ophthalmic hospital, a lying-in home, a hospital for women (Lady Havelock Hospital), a hospital for children (Lady Ridgeway's Hospital), a bacteriological institute, a Pasteur institute, a dental institute, and a home for incurables. At Angoda, six miles from Colombo, there is a hospital for infectious diseases, with 122 beds. There are special dispensaries at Kandy, Galle, Jaffa, and Batticola for the treatment of eye diseases. There is a lunatic asylum at Angoda and two leper asylums—one at Hendala in the Western Province and one at Mantivu in the Eastern Province. As regards the prevention of tuberculosis, in Colombo there is the King Edward VII Ante-Tuberculous Institute, at Kandana there is a sanatorium of 72 beds, and at Ragama there is a hospital for chronic cases. In addition to government hospitals, the owners of estates have provided 81 estate hospitals. There are also 575 central and branch dispensaries provided by government, and 684 estate dispensaries.

A Year's Work.

Dealing with the work of the year, the report states that the campaign against ankylostomiasis was continued, and in addition to the treatment afforded to the general public at hospitals and dispensaries throughout the island, 107,435 school-children and 124,336 estate coolies were treated by medical officers of the campaign staff. The activities of the anti-malaria campaign also were maintained at Chilan, Kurunegala, Anuradhapura and Trincomalee. An ordinance for the prevention of mosquito-breeding has been placed before the Legislative Council. Quinine was distributed very widely throughout the island. The number of persons treated at the Pasteur institute was 1448.

During the year there were in Colombo 40 cases of plague, 37 of which were fatal, this being the second lowest number of cases of death on record since the first appearance of plague in 1914. Out of the 40 cases, 27 were of the bubonic type and 13 of the septicæmic. All the septicæmic cases proved fatal, while the three recoveries were among those suffering from the bubonic type. Plague broke out in Kandy in the last quarter of 1927, and before the end of the year there were altogether 30 cases (26 fatal). By the beginning of 1928 the disease was got under control, and there were only eight further cases (six fatal). There were five cases of cholera in the island, of which four were fatal, compared with 11 cases and six deaths in 1927. There were 16 cases of small-pox with one death, as against 27 cases and five deaths in 1927.

Vital Statistics.

The estimated population of Ceylon on Dec. 31st, 1928, was 5,421,861. The total number of arrivals during the year amounted to 289,762, and of departures to 237,670. Of the former, 93 per cent. came from India, and of the latter, 92 per cent. were bound for India. The racial distribution of the population was, at the time of the last census (1921) as follows:—Europeans, 8118; Burghers and Eurasians, 29,439; Sinhalese, 3,016,145; Tamils, 1,120,059; Moors, 284,964; Malays, 13,402; others, 26,469. The births registered during the year numbered 213,311 (108,841 males and 104,470 females), being higher than the number registered in any previous year since registration was introduced. The birth-rate was equal to 40·0 per 1000 of the estimated population, as against 39·5 in the preceding year, and 38·8 the average for the ten years 1918-1927. The deaths of 123,337 persons were registered in 1928, as against 113,853 in 1927, and 138,853 the average for the previous ten years. The death-rate for 1928 was equal to 21·8 per 1000 of the estimated population, and 3·1 per 1000 higher than that recorded in 1927. The average for the past decade was 28·5. The number of infant deaths in 1928 was equal to a rate of 177 per 1000 births, as against 160 in 1927, and 188 the average for the past ten years. The birth-rate in Ceylon is very high compared with that prevailing in some western countries. The infant mortality-rate is greatly influenced by the birth-rate, so that it is not an unusual feature to find a high infant mortality-rate in countries that have high birth-rates and a low infant mortality-rate in countries that have low birth-rates. Though the Ceylon rate when judged by the standards of advanced western countries appears to be unsatisfactory, there is not much cause for apprehension when the climatic and other conditions in the island are taken into account.

Causes of Death.

The classification of causes of death is based on the international or Bertillon system. This was originally introduced into Ceylon in 1911, and has since undergone a revision. The revision, which is that of 1920, has been in use here for the last two years only. Owing to the absence of compulsory certification of causes of death among a very large section of the population, the statistics, particularly of diseases requiring scientific knowledge for diagnosis, are of doubtful value, but there is reason to believe that a definite though slow progress in accuracy is achieved every year. Owing to lack of certification a very large number of deaths appear under the heading "pyrexia," which is admittedly a vague cause of death. This cause, which includes all cases of fever not otherwise defined, was stated in the deaths of 18,051 persons—or 14 per cent. of the total deaths. In the previous year 13,502 deaths were registered under the cause. There is no doubt that a considerable number of the deaths so registered were actually due to malaria, but in the absence of their being so stated in the returns by village registrars, the deaths are classified under the general heading "pyrexia." Another prolific cause of death in the island is infantile convulsion, from which during the year under review there were 16,042 deaths—or 12 per cent. of the total deaths. The death-rates from some of the more important diseases registered in Ceylon in 1928 as per million of the estimated population were:—pyrexia, 3553; infantile convulsions, 3007; pneumonia, 1658; diarrhœa and enteritis, 1655; dysentery, 616; phthisis, 631; malaria and malarial cachexia, 420; premature birth and congenital defects, 419; ankylostomiasis, 405; influenza, 307; puerperal septicæmia, 204; bronchitis, 239; enteric fever, 108; cancer, 103.

REGIMENTAL COLOURS OF THE INDIAN ARMY.

To the Editor of THE LANCET.

SIR,—I am collecting information regarding the regimental colours, past and present, of the Indian army, and should be particularly grateful if any of your readers could assist me in tracing some flags once in the possession of a Surgeon-Major Newton, who lived at Cheltenham many years ago.

I am, Sir, yours faithfully,

H. BULLOCK (Capt.).

East India United Service Club, St. James's-square, S.W.,
Dec. 3rd, 1929.

ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.

THIS hospital is to be congratulated on its first medical report. The period covered is from April 1st to Dec. 31st, 1928, during which time 2033 in-patients were treated and 1836 operations were performed. The classification of cases is done clearly on pathological lines and it should have considerable statistical value; a useful distinction is made between parous and nulliparous patients. It is hoped that the governors of the hospital will make the production of this report an annual event.

Dr. R. M. B. MacKenna desires to state that the public advertisements issued in the Seacombe district of Liverpool last week with regard to a lecture on a "lay" topic which he delivered on Nov. 24th, were issued without his knowledge or consent, and that he demanded their immediate obliteration within half an hour of learning of their publication.

An Address

ON

MODERN RADIOLOGICAL DEVELOPMENTS IN GERMANY.

Delivered at the Annual Meeting of the Institute of Radiology, Incorporated with the Rontgen Society, on Dec. 6th

BY FFRANGCON ROBERTS, M.D. CAMB.,
M.R.C.P. LOND.,

ASSISTANT PHYSICIAN, IN CHARGE OF THE X RAY DEPARTMENT, ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

I PROPOSE first to describe the remarkable strides which radiology is making in Germany at the present day; secondly, to say something of the economic aspects of the movement; and thirdly, to offer a few suggestions for the improvement of radiology in this country.

A MODEL INSTITUTE.

I shall begin by giving an account of the new radiological institute at the Städisches Krankenhaus or municipal hospital at Frankfort-on-Maine. This institute, which is under the direction of Prof. Holfelder, has only just been opened and is probably the most modern and the best equipped in Europe. The building consists of three floors and a basement. The basement is given up mainly to diathermy, ultra-violet light, and to photographic work other than the actual developing of X ray films. There are six cubicles for diathermy, while for light treatment there are four double cubicles and a large room for children.

The *ground floor* is entirely for radiographic diagnosis. On one side of the main corridor are six large rooms in all of which screening can be carried out. The first room is adapted for operative work such as pyelography and myelography; the second, third, and fourth rooms are for gastro-intestinal work, the fourth being also used for the heart and lungs; the fifth is for the skull and teeth, and the sixth for the limbs. Each room is provided with two dressing-rooms which open at one end into the corridor and at the other into the screening-room. By this means the preparation of patients is carried out with the minimum of inconvenience. Adjoining each screening-room is a small cabin containing the switchboards. This cabin is separated from the screening-room by barium-brick walls and a lead glass window, but by an ingenious device the operator, while completely protected from X rays, can easily hear the instructions called out by the person carrying out the investigation. The high tension apparatus—and this is a great feature of the institute—is housed on a *mezzanine floor* directly above the control cabins and dressing-rooms. Thus the amount of apparatus in the screening-rooms is reduced to a minimum and a greater safety both for the apparatus and for those who come in contact with it is assured. A window in the ceiling of the cabin permits the operator to read the output of the machine as registered on the clocks above. On the opposite side of the corridor are the developing-rooms, a large room for washing, drying, and viewing films, this room being also used for lectures, a kitchen for the preparation of barium meals, waiting-rooms both for ambulatory and bed patients, and administrative offices.

The *first floor* is for X ray therapy. This is carried out in two large cheerful well-ventilated rooms with big windows. In each room are three large therapy tubes enclosed in so-called "cannons," in the design of which Prof. Holfelder has to my mind displayed great ingenuity. They project horizontally into the room from a semi-octagonal glass enclosure through which they connect to the high-tension apparatus placed on the floor above. They can be raised or lowered and rotated through a horizontal axis with the greatest ease, with the result that any part of the body can be treated with very little discomfort to the patient. They are also perfectly shock-proof; any part of the outside of the cannons can, in fact, be freely handled while the tube is in operation. A further point is that no radiation can escape unless a filter is in position. Patient, operator, and attendant are thus quite free from danger. There is nothing to alarm the patient or to give him a feeling of despair as is so often the case in rooms devoted to this purpose. On the contrary, he finds himself in a atmosphere of cheerfulness and hope. The control cabins are arranged as previously described for diagnosis. On the opposite side of the corridor are waiting-rooms and rooms for surgical dressings, for examining patients, and for special investigations such as basal metabolism. On this floor, too, are the director's room, offices, and a library.

On the *second floor* is the high-tension plant for therapy. These are of the "stabilivolt" or condenser type, the current being led below through gaps in the floor into the semi-octagonal enclosures already described and thence into the cannons. A small room at the end is for standardisation and is so arranged that any apparatus at will can be connected with the measuring instruments. The remainder of this floor contains storage-rooms for films, workshops, and quarters for the resident staff.

The cost of this building, excluding the actual apparatus but including the furniture, fittings, and wiring, was about £25,000, or £2 14*s.* per cubic metre. The expense was borne partly by the hospital—that is to say, by the State, for this hospital, like most in Germany, is State-controlled—and partly by the Allgemeine Ortskrankenkasse which is the largest insurance society in Germany. This society, by way of lessening its expenditure on X ray fees, had intended building its own department, but decided that the interests of economy would be better served by combining with the hospital.

The institute has been designed to cope with 120–200 radiological examinations and 90–120 treatments per diem. It may be thought that this accommodation would satisfy the needs of Frankfort with its 500,000 inhabitants. Such, however, is very far from being the case, for there are many other X ray departments in the town, and even in the same hospital there is another, attached to the medical clinic, where at least as much X ray diagnosis is being carried out as in Prof. Holfelder's institute.

OTHER RADIOLOGICAL DEPARTMENTS.

Passing now to other towns, I found that at Mannheim under Dr. Diederich there was a radiological department which would have more than satisfied me, but this was going to be scrapped and a more modern one built. At the large Burger hospital at Cologne under Prof. Grashey I saw an entirely new department on the lines of the one at Frankfort in course of erection. In some ways the most remarkable department which I saw was not in a hospital at all but belonged to the Allgemeine Ortskrankenkasse at Cologne. This society has built and equipped on the top floor of its head office what I can only describe as a model of its kind, though it is not so large as the one at Frankfort. Here Dr. Teschendorf and his assistants carry out from 100–200 examinations each day as well as a considerable amount of therapy. I was informed that though it is primarily intended for members of the society these are perfectly at liberty to go elsewhere for radiographic examination if they wish, while on the other hand members of other societies are admitted on a recognized scale of fees. Private patients are also taken to the mutual benefit of the society and its radiologists.

WHERE GERMANY LEADS.

I have said enough to show that Germany is overwhelmingly superior to this country both in the extent to which radiology is applied and also in equipment and organisation; and this is the more remarkable when the resources of the two countries are compared. It should be stated, however, that the liberality with which radiology is being endowed is part of the general policy of the Government to spend money lavishly on all matters affecting the health of the nation, not medical services merely but also housing, public baths, recreation-grounds, and so on. A gigantic experiment in social welfare is in fact being undertaken, and many social observers are wondering whether the end is going to justify the means. But while it may be argued that Germany is erring on the side of extravagance it is, I think, indisputable that in this country the standard of equipment is far from satisfactory.

I can imagine few British radiologists returning from a visit such as mine without a feeling of envy towards their German colleagues, who appear to an outside observer to have no difficulty in obtaining all that they require. Criticism of the way in which radiology is carried out in this country has not been wanting. A year ago, for instance, Sir Thomas Horder complained that physicians' consulting-rooms were filled with worthless X ray films, while in the Annual Report of the Medical Research Council the fact is deplored that no definite school of radiotherapy has sprung up in England comparable to Vienna and other continental schools. While we must not lose sight of the fact that in the long run the man is more important than the machine and that an efficient radiologist with inferior apparatus is better than an indifferent radiologist with first-class apparatus, it may reasonably be replied to these criticisms that some allowance should be made for the technical limitations with which most radiologists in this country have to contend.

I should be sorry if any of my remarks were to be interpreted as casting a reflection upon the competence of British manufacturers. Nothing could be further from my intention. I saw nothing in Germany which so far as I could judge could not be made in England. My sympathies are very much with the British manufacturers, since in comparison with their German competitors they have a small market and must consequently experience great difficulty in expanding their business.

WHAT CAN BE DONE IN ENGLAND.

It appears to me that there are four directions in which this country should move without going to the lengths which Germany has gone.

(1) *Centralisation of apparatus.*—No other branch of medicine involves anything like so large a capital outlay, such heavy running expense, or such extensive accommodation. No other specialist starts practice at so great a financial risk. A surgeon, for example, is not expected at the beginning of his career to equip his own operating theatre and nursing home. The radiologist, unless he happens to be fortunately situated, may be compelled in order to make himself efficient to pledge his credit to an extent which the financial state of the district in which he works does not justify—and all this in order to provide himself with apparatus which is rapidly depreciating in value and is duplicated in the hospital where he works. In Germany the admission of private patients to the X ray departments of general hospitals is the rule, and all the radiologists with whom I discussed this question told me emphatically that they had no desire to burden themselves with their own apparatus. It is true, of course, that in Germany radiologists are paid for their ordinary hospital work, but then they need to be since the proportion of paying patients to the total population is lower there than in England. I am aware that there are many hospitals in this country where this practice has already been adopted with complete success. My point is that it should be carried a great deal further, especially in the poorer districts.

Is, then, private radiology as generally carried out doomed to extinction? I do not think so, since there will always be people who have an intense aversion to institutional treatment. But what I do believe is that as the work becomes more and more complex considerations of space and finance will make it increasingly difficult to practise radiology within the confines of a dwelling-house. Centralisation will mean greater efficiency as well as greater economy.

(2) *Payment to hospital for motor accident cases.*—This question is now very prominently before the public, and the claims of hospitals in this respect have been well expressed by Sir Charles Harris in the *Times* of Nov. 30th. I need only call attention here to the fact that all such accidents of any severity require X ray examination.

(3) *Payment to hospitals from National Insurance Fund.*—It is obvious to anyone that if hospitals were paid for radiological diagnosis and treatment under the Insurance Acts the whole position of radiology would be revolutionised. I am strongly of opinion that this is a matter on which the British Institute of Radiology might well ask for an investigation.

(4) *State grants to hospitals for X ray equipment.*—The proposal to demand grants from the State will naturally meet with opposition from those who pin their faith in the voluntary system. But the high cost of radiology and the increasingly important part it plays gives this branch of medicine a special claim for support from a more reliable source. The State already supports the treatment of many conditions and in particular those such as tuberculosis and venereal disease which the public has proclaimed to be a national scourge. But cancer is now recognised as a national scourge, and those who try to educate the general public on the dangers of this disease are quite rightly never tired of emphasising the importance of early diagnosis. They might well add that in many forms of cancer radiology provides the surest means of early diagnosis, while in nearly all forms it is one of the principal means of treatment. It is therefore to the public interest to see that the work is carried out efficiently. The Government responded to the appeal for radium, though it is only fair to say that in this case it was a matter of limited commodity, and it is an arresting thought that had it not been for the King's illness and recovery the country might never have acquired a quantity of radium sufficient for its needs. A further claim for State support is the logical outcome of the Local Government Act of 1929, for since under this Act the voluntary hospitals will be required among other things to provide radiological facilities for the county council hospitals, the State should be required to provide some share of the equipment in addition to reimbursing the hospitals for running expenses. So far as I am aware—and I speak open to correction—the special claims of radiology for State support have never been presented. It appears to me that the British Institute of Radiology is the body which is most competent to bring influence to bear upon the proper quarter. It should insist that the proper prosecution of the important branch which it represents is not handicapped through lack of funds.

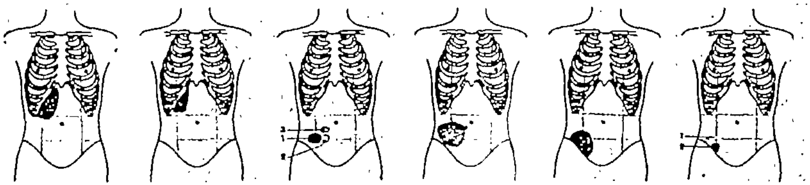
THE SIGNIFICANCE OF THE AFFERENT IMPULSES FROM THE SKIN IN THE MECHANISM OF ABDOMINAL PAIN.

BY JOHN MORLEY, CH.M. MANCH., F.R.C.S. ENG.,
HON. ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY;
HON. CONSULTING SURGEON, ANCOATS HOSPITAL;
LECTURER IN APPLIED ANATOMY,
MANCHESTER UNIVERSITY.

A RECENT paper by Weiss and Davis[1] recorded some important observations on a series of patients with localised thoracic or abdominal pain. These authors found that infiltration of the skin over the painful area with novocain caused abolition or diminution of the pain, and they make the remarkable claim that their findings afford experimental proof of the truth of Mackenzie's viscero-sensory reflex theory of referred pain. Their observations and the theoretical deductions that they based upon them seemed to me to be of such importance as to demand a critical investigation. The paper that follows describes a series of cases investigated in a similar manner to those of Weiss and Davis, and attempts, in the light of the results obtained, to assess the validity of their conclusions.

In this investigation, as in that of Weiss and Davis, the localised area in which the pain was felt was infiltrated with novocain as closely to the skin as possible, the deeper layers of subcutaneous tissue not being injected. But whereas they used a solution of 2 per cent. novocain I have thought it safer, in view of the wide area of skin infiltrated in some cases, to employ 1 per cent. novocain, to which a little adrenalin has been added. The object kept in view was to ascertain the effect of the infiltration in each case upon (1) the spontaneous pain, (2) the pain felt on coughing, (3) the objective cutaneous hyperalgesia as tested by light pinching of the skin, and (4) the deep tenderness and associated muscular rigidity. In this way I have attempted to obtain more precise objective findings than Weiss and Davis, who only mention such factors as deep tenderness and muscular rigidity in a few of their cases.

FIG. 1. FIG. 2. FIG. 3. FIG. 4. FIG. 5. FIG. 6.



(Case 1.) (Case 2.) (Case 3.) (Case 4.) (Case 5.) (Case 6.)

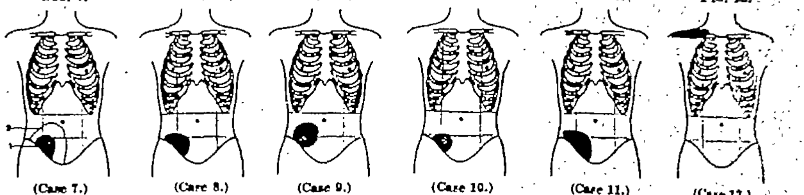
In Figs. 1, 2, 3, 4, and 6 the black represents an area of pain, deep tenderness, and rigidity; in Fig. 5 it represents an area of localised tenderness. Fig. 3 shows (1) the original area of pain, deep tenderness, and rigidity; (2) the area to which pain migrated after area (1) was infiltrated; and (3) the area to which it further migrated after infiltration of area (2). Fig. 6 shows (1) an area of cutaneous hyperalgesia; and (2) an area of pain, deep tenderness, and rigidity.

Only such patients as had distinctly localised pain and whose mental condition allowed their willing coöperation were investigated.

Observations.

CASE 1. *Acute obstructive cholecystitis*—Female, aged 64. Sudden onset of acute epigastric pain 24 hours before admission. The pain had settled down to the right hypochondrium, going through to the back. No shoulder-tip pain. History of two similar attacks recently. On admission: Temperature 101° F.; pulse-rate 100. Spontaneous pain in right hypochondrium and angle of right scapula. The pain in front was worse on coughing. Cutaneous hyperalgesia in shaded area (Fig. 1.) Deep tenderness and rigidity in shaded area. Enlarged gall-bladder vaguely palpable. The shaded area was infiltrated subcutaneously with 1 per cent. novocain until completely anæsthetic to pinprick. The spontaneous pain had now disappeared. On coughing the patient felt some pain, but less than before infiltration. Cutaneous hyperalgesia absent. On deep pressure she "couldn't feel much difference" from the tenderness before infiltration, nor could any diminution of rigidity be detected. Operation: Spinal anæsthetic with stovaine-glucose. Gall-bladder very distended, with patches of green gangrene on fundus, and a small stone impacted in cystic duct. Cholecystectomy.

FIG. 7. FIG. 8. FIG. 9. FIG. 10. FIG. 11. FIG. 12.



(Case 7.) (Case 8.) (Case 9.) (Case 10.) (Case 11.) (Case 12.)

Fig. 7 shows (1) an area of pain, deep tenderness, and rigidity; and (2) an area of cutaneous erythema. Fig. 8 shows an area of pain, deep tenderness, and rigidity, while Figs. 9–11 also show areas of pain and deep tenderness. Fig. 12 illustrates Case 13, a case of duodenal ulcer, and indicates the position of the pain in the right shoulder-tip.

CASE 2. *Acute obstructive cholecystitis.*—Male, aged 37. Onset of acute pain in right hypochondrium 12 hours before admission. On admission: Spontaneous localised pain, deep tenderness, and muscular rigidity in shaded area (Fig. 2). No cutaneous hyperalgesia. The area of pain was infiltrated with 1 per cent. novocain till anæsthetic to pinprick. States that pain has now disappeared. On palpation muscular rigidity seems perceptibly less. Patient states that deep tenderness is still present, but "nothing like so tender as it was." Operation: Acutely inflamed distended gall-bladder with solitary stone, the size of a walnut, impacted in its neck. Cholecystectomy.

CASE 3. *Acute appendicitis.*—Female, aged 20. Onset of acute pain 20 hours before admission. Pain central at first, shifting to right iliac fossa. On admission: Spontaneous pain, worse on coughing, in right iliac fossa. No cutaneous hyperalgesia. Deep tenderness and moderate rigidity in same area as pain (Fig. 3). The area of skin over deep tenderness was infiltrated with novocain till anæsthetic to pinprick. Patient was then asked to cough, and said she now felt the pain, not in the anæsthetised area, but nearer the midline. This more medial area was then infiltrated, and on coughing again some pain was felt a little higher up. Deep tenderness was now tested, and was "not so tender as before." Operation: Appendix covered with plastic lymph and curled up below cæcum. It was not perforated.

CASE 4. *Acute perforated appendix with localised abscess.*—Female, aged 32. Acute onset four days before admission. On admission: Localised pain in right iliac fossa, much worse on coughing. Cutaneous hyperalgesia well marked in shaded area (Fig. 4). Deep tenderness in same area, and some muscular rigidity. The skin was infiltrated with novocain, till anæsthetic to pinprick. Spontaneous pain had now disappeared. Pain on coughing still present, but definitely less. Deep tenderness still present, and patient could not appreciate any diminution in intensity. Operation: Spinal anæsthesia. Appendix in retrocæcal fossa, gangrenous and perforated, with abscess tracking into right lateral paracolic groove.

CASE 5. *Acute appendicitis with localised abscess.*—Male, aged 23. Onset six days before admission. On admission: Localised *tender mass in right iliac fossa* (Fig. 5). No spontaneous pain, or pain on coughing. No cutaneous hyperalgesia. The skin was infiltrated with novocain over tender area till anæsthetic to pinprick. On deep pressure patient at first stated that tenderness over mass was diminished, but when pressure was increased he doubted whether there was any real difference as compared with initial tenderness. Operation: Gangrenous appendix with localised abscess wrapped round by infiltrated omentum.

CASE 6. *Acute appendicitis with localised abscess.*—Female, aged 19. Onset of acute epigastric pain 21 hours before admission. On admission: Sharp spontaneous pain in right iliac fossa, worse on coughing. Area of deep tenderness and rigidity, with smaller area of cutaneous hyperalgesia (Fig. 6). The skin over area of deep tenderness was infiltrated till anæsthetic to pinprick. Cutaneous hyperalgesia and spontaneous pain had now disappeared, but pain on coughing still present, and deep tenderness and muscular rigidity also present. Patient stated that deep tenderness was less than before infiltration. This could not be confirmed by any change in the rigidity. Operation: Collection of pus in contact with parietal peritoneum just above middle of Poupart's ligament. Appendix hanging over brim of pelvis and perforated near tip. Uterus two months pregnant.

CASE 7. *Acute obstructive appendicitis with gangrene.*—Male, aged 18. Onset of epigastric pain 36 hours before operation. Pain shifted after a few hours to right iliac fossa. First attack. On admission: Skin erythematous from use of hot-water bottle. No spontaneous pain, but sharp pain in shaded area on coughing (Fig. 7). Cutaneous hyperalgesia present, but discounted on account of erythema. Marked deep tenderness and rigidity in shaded area. The shaded area was infiltrated with 40 c.cm. 1 per cent. novocain and adrenalin till anæsthetic to pinprick. Patient was then asked to cough, and said that he still felt pain "just the same as before." On deep pressure tenderness was still felt, but he said "I don't think it is quite so bad as before." Rigidity was unchanged. Operation: Appendix hanging over brim of pelvis. Hard concretion obstructing it one inch from tip, and part distal to this gangrenous but not yet perforated. There was a small amount of fluid round the appendix.

CASE 8. *Acute appendicitis.*—Male, aged 34. Onset of acute pain in epigastrium 20 hours before operation. After a few hours this pain disappeared, and sharp localised pain in right iliac fossa began. Two previous milder attacks. On admission: Slight spontaneous pain in right iliac fossa while lying still; much more marked on coughing. The initial epigastric pain had quite disappeared. No cutaneous hyperalgesia. Very marked rigidity and deep tenderness in shaded area (Fig. 8). The shaded area was infiltrated subcutaneously with 1 per cent. novocain until anæsthetic to pinprick. The slight spontaneous pain could not now be felt, and on coughing the sharp pain noted before the infiltration was not felt at all. On palpation there was no perceptible diminution in the muscular rigidity, nor in the associated deep tenderness. Operation: Acutely inflamed appendix with tip on outer side of cæcum. Not perforated.

CASE 9. *Acute appendicitis.*—Female, aged 12. Onset with central epigastric pain 45 hours before operation. First attack. On admission: Slight spontaneous pain in right iliac fossa, worse on coughing. Hyperalgesia of skin and deep tenderness in shaded area (Fig. 9), but not much rigidity. No tenderness or pain in back of loin. The skin was infiltrated with novocain till anæsthetic to pinprick. Spontaneous pain and pain on coughing now disappeared. Hyperalgesia was absent. Pain on deep pressure was still present, though she stated it was distinctly less than before infiltration. Operation: Appendix curled up behind lower ileum, which protected it from immediate contact with anterior parietes. Acutely inflamed, but not perforated.

CASE 10. *Acute appendicitis.*—Female, aged 35. Onset 24 hours before operation, with central pain, shifting to right iliac fossa. On admission: Spontaneous pain, not very severe, in shaded area (Fig. 10). Marked pain on coughing felt in same area. No cutaneous hyperalgesia. Deep tenderness limited to shaded area. Little muscular rigidity. The shaded area was infiltrated with novocain till anæsthetic to pinprick. Spontaneous pain was now "much less." Pain on coughing also "much less." Pain on deep pressure still marked, but "rather less tender." Operation: Kinked and swollen appendix, distended with pus, in retrocæcal fossa. No perforation.

CASE 11. *Acute salpingitis.*—Female, aged 24. Onset of pain in right iliac fossa two days before admission. No initial central pain. No urinary symptoms. On admission: Cutaneous hyperalgesia marked in shaded area (Fig. 11). No spontaneous pain, but pain on coughing. Deep tenderness over same area as hyperalgesia. Little muscular rigidity. Temp. 100° F. Pulse 108. The area was infiltrated with novocain subcutaneously till anæsthetic. Pain on coughing abolished completely. Deep tenderness much less marked. Operation: Turbid fluid in right iliac fossa and pouch of Douglas with fibrin on coils of ileum in pelvis. Left tube was congested, and muco-pus was found escaping from fimbriated end.

Discussion.

Summarising the findings from these 11 cases, we note the following results of the subcutaneous infiltration with novocain:—

Spontaneous pain.—Present in 8 cases; complete relief, 6; partial relief, 2; unchanged, 0; not present, 3.

Pain on coughing.—Present, 9; complete relief, 3; partial relief, 4; unchanged, 2; not present, 1; not noted, 1.

Deep tenderness.—Present, 11; complete relief, 0; partial relief, 8; unchanged, 3.

Rigidity.—Present, 11 (4 slight); completely abolished, 0; diminished, 1; doubtful, 3; unchanged, 7.

It will be observed that the most striking positive effect was the abolition of the spontaneous pain, which occurred in six out of eight cases. The effect on pain felt on coughing was less marked, though still definite. On deep tenderness the effect was slight, and on muscular rigidity it was hardly appreciable. Hyperalgesia, when present, was abolished inevitably by the infiltration.

These results afford, on the whole, a striking confirmation of the experimental findings of Weiss and Davis, though the type of case selected in the two investigations was somewhat different. Thus Weiss and Davis include in their 25 cases 3 of angina pectoris, 7 of pulmonary disease with pleurisy, 1 of carcinoma of the œsophagus, 1 of gastric ulcer, 4 of cholecystitis, 2 of appendicitis, 5 of renal conditions, and 2 of salpingitis, while I have confined my attention to acute abdominal lesions that could be verified immediately by operation. But while my results go to confirm their very important observations, it is necessary to make some critical remarks about their theoretical deductions. They claim that the abolition of pain by cutaneous anæsthesia proves the truth of the theory of referred pain in visceral disease, which we owe to the late Sir James Mackenzie. "According to this view, painful sensations arise as a result of irritation to a viscus. Such irritation produces a play of nervous impulses, which pass from the irritated viscera *along the splanchnic nerves*" (the italics are mine), "to certain segments in the cord. The perpetual bombardment of this cord segment with visceral impulses gives rise to an 'irritable focus' in the cord. The normal afferent impulses arising from the skin, muscles, and peripheral structures which traverse this segment now enter a cord region which is abnormally irritable. These normal impulses under such conditions give rise to painful sensations which are referred to the peripheral structures." But it cannot be admitted that these experiments prove the truth of the above viscero-sensory reflex theory of referred pain, any more than they prove the truth of my alternative theory of peritoneo-cutaneous radiation. In a paper on abdominal pain as exemplified in acute appendicitis[1] I have brought forward evidence for the view that the localised pain in the right iliac fossa in acute appendicitis (unlike the initial epigastric pain, which is a pure visceral pain), results from the stimulation of the exquisitely sensitive parietal peritoneum, and that the afferent splanchnic nerves from the appendix are not in any way concerned in its production. A reference to Figs. 13 and 14, in which these two conflicting theories of referred pain are represented diagrammatically, will show at a glance that the experiments under discussion have a precisely equal validity in the case of each theory. They no more prove one theory than they prove the other. But they may logically be held to prove that *either* the one theory *or* the other is the true explanation of referred pain.

Weiss and Davis do not appear to have taken into consideration the theory of peritoneo-cutaneous radiation at all when discussing the results of their investigations. They do make the comment, when discussing their cases of pleurisy: "It is to be remembered, also, that pain of pleural origin may be partly due to the direct sensitivity of the parietal pleura. It is recognised that the parietal pleura receives direct nerve-supply from the intercostal nerves." But the conception of a pleuro-cutaneous radiation of pain receives no attention at all. Yet I believe that their experiments afford as much proof of pleuro-cutaneous radiation of pain in pleurisy as of a viscero-sensory reflex from the afferent splanchnic nerves of the lung.

Two Conflicting Theories.

We have now arrived at a point in the argument where the experiments of Weiss and Davis, and those recorded above, leave us unable to decide between the relative claims of the two conflicting theories of referred pain—viz., the viscero-cutaneous reflex theory and the peritoneo-cutaneous (or pleuro-cutaneous) radiation theory. What these experiments prove, no more and no less, is that one or other theory is true. (It is so obviously improbable that *both* theories are true, that I do not consider that possibility in the present discussion.)

In attempting to find a method by which the merits of my theory of peritoneo-cutaneous radiation could be put to a more convincing experimental test, I naturally thought of the peculiarly striking form of referred pain in the shoulder-tip area associated with painful stimulation of the sensory fibres of the phrenic nerves in the peritoneum (or pleura) lining the diaphragm. I have already [8] drawn attention to the invariability with which the pain in the shoulder-tip area is felt when the under surface of the diaphragm is stimulated by an irritating fluid, as in perforation of an ulcer, or when, under spinal anæsthesia, a swab is brought into contact with the under surface of the diaphragm. It was, in fact, mainly from a study of this shoulder-tip pain that I elaborated my theory of peritoneo-cutaneous radiation. Pain localised to the supra-acromial region, resulting from irritation below the diaphragm, would provide exactly the test that we require, since all question of the agency of splanchnic nerves can there be set aside. It is universally admitted that the painful stimulus passes up the sensory fibres of the phrenic nerve derived from the third, fourth, and fifth cervical segments, and that the pain is felt, not in the region of the diaphragm, but in those areas of skin over the shoulder supplied by the descending cervical nerves, which originate from the same cervical segments of the cord. The "irritable focus" theory is one possible explanation of this radiation of pain. According to this theory the normally silent afferent impulses from the cutaneous nerves over the shoulder become painful, though whether the "bombardment" from the parietal peritoneum affects the posterior horn cells or the cells of the posterior root ganglia it is not possible at present to be certain. If it could be shown, then, that infiltration of the shoulder-tip area of skin with novocain abolished shoulder-tip pain, very strong evidence in favour of the theory of peritoneo-cutaneous radiation would be forthcoming.

FIG. 13.

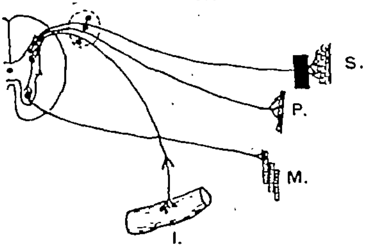


Diagram to illustrate Mackenzie's theory of viscero-sensory and viscero-motor reflex, and the effect, according to this theory, of cutaneous anæsthesia. In this figure and Fig. 14 S = skin; P = parietal peritoneum; M = muscles of abdominal wall; and I = intestine or appendix.

The following cases were investigated in order to obtain light on this question.

CASE 12. *Perforated duodenal ulcer.*—Male, aged 86. Perforated five hours before operation. On admission: Diffuse abdominal pain and rigidity with pain in the posterior part of the right shoulder-tip area, mainly over the suprascapular fossa. The shoulder-tip area was infiltrated with 1 per cent. novocain until anæsthetic to pinprick. Pain in the shoulder-tip area could no longer be felt. Operation: Spinal anæsthesia with stovaine-glucose. Perfect anæsthesia of abdominal wall extending to about the fifth dorsal segment. Right paramedian incision. While the abdomen was being opened, the patient volunteered information that he now felt pain in the tip of the left shoulder, but not in the right as before infiltration. A perforated ulcer was found in the first part of the duodenum, anterior wall, with a fair amount of extravasated fluid. The perforation was sutured. A moist swab was then passed up between the liver and the right dome of the diaphragm. At first no pain was felt. He then complained of some pain in the right shoulder-tip area. A similar swab passed up under the left dome of the diaphragm produced much more severe pain in the left shoulder immediately. This was repeated twice, and each time the difference between the two sides was most striking, judging both by the patient's statements and by the expression of his face. The left, unanæsthetised, shoulder was the seat of much more acute pain.

FIG. 14.

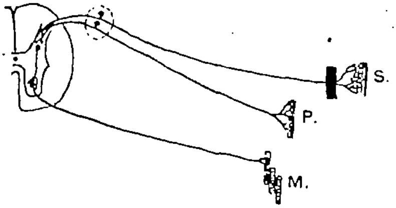

Diagram to illustrate theory of peritoneo-cutaneous radiation and peritoneo-muscular reflex, and the effect, according to this theory, of cutaneous anæsthesia.

CASE 13. *Perforated duodenal ulcer.*—Male, aged 55. Sudden onset of severe pain 5½ hours before operation, when lifting some timber. Patient had had a perforated duodenal ulcer sutured 11 months before. On admission: Great pain in abdomen and in right shoulder-tip (Fig. 12). Diffuse board-like rigidity of abdominal muscles. Although the spontaneous right shoulder-tip pain was quite unusually severe there was no hyperalgesia of the skin in that area on pinching it lightly. The right shoulder-tip area was now infiltrated with 1 per cent. novocain till anæsthetic to pinprick. Patient now stated that pain in the right shoulder was "easier." Operation: Spinal stovaine-glucose. Good anæsthesia of abdominal wall. On opening the abdomen through a right paramedian incision a perforation was found in the first part of the duodenum, with a large collection of fluid in the right subhepatic and right anterior subphrenic spaces, partly shut off from the general peritoneal cavity by adhesions from the earlier perforation. The perforation was sutured. On swabbing between the right lobe of the liver and the right dome of the diaphragm patient felt some pain in the right shoulder-tip. On swabbing in a similar manner under the left diaphragm, where no irritating fluid was found, a much more agonising pain in the left shoulder-tip area was complained of. Posterior gastro-enterostomy was performed.

It was thus found that infiltration of the shoulder-tip area abolished the spontaneous shoulder-tip pain in Case 12, and gave partial, but very marked relief, in Case 13. The unusual severity of the shoulder-tip pain in Case 13, due to the adhesions which caused a localisation of most of the extravasated fluid to the space under the right dome of the diaphragm, must be borne in mind. But the most striking phenomenon in each case was the marked difference between the intensity of the pain in the two shoulders, when a painful stimulus in the shape of a swab was applied to both domes of the diaphragm in the process of cleansing the peritoneum. The difference was so marked as to impress all the onlookers, while the patients commented on it days afterwards. It should be remembered that in each case the extravasation had been chiefly localised to the right *subphrenic space*, so that the sensory nerves on that side would presumably be in a more irritable condition. In spite of this, anæsthesia of the skin over the right shoulder-tip area produced great diminution of the referred pain as compared with the side that was not anæsthetised.

The fact that shoulder-tip pain was not abolished completely may be attributed to the fact that the descending cervical nerves from the third and fourth cervical segments supply sensory fibres to the acromio-clavicular joint as well as to the periosteum of the acromion process and clavicle. Since care was taken to make the subcutaneous injection as superficial as possible, these fibres would escape the action of the novocain, and this would account for such shoulder-tip pain as persisted.

It can be stated with the greatest confidence that none of the novocain solution was injected anywhere near the trunk of the phrenic nerve, so that a possible fallacy in the experiments—viz., anæsthesia of the phrenic nerve—need not be considered.

Peritoneo-cutaneous Radiation.

We find, then, in the above two crucial experiments that anæsthesia of the skin in the shoulder-tip area produces no less profound a modification of pain than we have found on similar infiltration over an inflamed appendix or gall-bladder. There is every reason to suppose that the mechanism of the anæsthesia, as of the production of pain, is exactly similar in the two cases. The sensitive parietal peritoneum lining the diaphragm has the same protective function as the peritoneum lining the anterior abdominal wall, with which it is continuous. Its sensory innervation is, in all respects, similar, save that an embryological accident has widely separated the subphrenic peritoneum from its corresponding skin area. It is this accident, if so it may be termed, which provides us with the opportunity of studying the protective mechanism. For, in the study of shoulder-tip pain, the problem is simplified in that no question of radiation or reflex through the afferent splanchnic nerves can be entertained. The pain is produced by a process of peritoneo-cutaneous radiation. Anæsthesia of the skin over the shoulder, by cutting off the normal afferent stimuli, profoundly modifies the sensation of pain, though the direct afferent path through the phrenic nerve to the brain remains open.

There is every reason to believe that the experiments of Weiss and Davis will find their true explanation along similar lines.

Evidence that I have already brought forward (loc. cit.) shows that the pain over an inflamed appendix is so accurately localised that it must be dependent on stimulation of the afferent nerves in the parietal peritoneum, and not of the afferent splanchnic nerves. Precisely the same reasoning holds good as regards the localised muscular rigidity and associated deep tenderness over an acutely inflamed appendix. They correspond accurately with the position in which the appendix happens to be lying, and in an early case, before perforation has widened the area of irritation, they may be used to predict the precise position in which the appendix will be found at operation to lie. A relatively slight degree of muscular rigidity and deep tenderness in a case of early acute appendicitis means that the appendix is shielded from the anterior parietal peritoneum either by occupying the retrocæcal fossa or by a covering provided by a thick omentum or the lower coils of the ileum. These precise indications of the site of an inflamed appendix are quite inconsistent with the theory of a viscero-sensory or viscero-motor reflex through the agency of the afferent splanchnic nerves from the appendix. But they are consistent with, and afford the strongest evidence for, the theory of peritoneo-cutaneous radiation and peritoneo-muscular reflex.

The condition of acute obstructive cholecystitis, due to impaction of a stone in the cystic duct or neck of the gall-bladder, which provided Cases 1 and 2 in the above series, affords evidence leading to the same conclusion. It is not uncommon in such a case for a progressive enlargement of the inflamed gall-bladder to occur, due to distension with muco-pus. If such a case is observed carefully at intervals of a few hours, the area of maximum pain, corresponding with that of muscular rigidity and deep tenderness, will be found to creep gradually lower as the gall-bladder becomes more distended, until it may be so low in the right abdomen as to give rise to difficulty in differentiating the case from one of acute appendicitis. The site of the maximum pain, tenderness, and rigidity must be determined by contact of the fundus of the inflamed gall-bladder with the parietal peritoneum. For, were the process a viscero-sensory and viscero-motor reflex, the maximum pain, tenderness, and rigidity would be constant in position, since they would be determined by the segmental splanchnic innervation of the gall-bladder.

If due weight be given to these arguments it will be found that these infiltration experiments, so far from supporting Mackenzie's viscero-sensory reflex theory, afford convincing support to the alternative theory of peritoneo-cutaneous radiation.

The question of pure visceral pain does not arise in these infiltration experiments, since all the cases dealt with showed accurately *localised* pain. While the existence of true visceral pain has been abundantly demonstrated by Hurst and others, it is a vaguely localised central pain, and is entirely unassociated with localised tenderness or rigidity. The pure visceral pain, which occurs in most cases of acute appendicitis for instance, is only present for the first few hours, and, though felt in the centre of the abdomen, is usually described by the patient as "all across." It would be quite impossible to carry out these infiltration experiments in that early stage, for one could not determine how wide an area of skin to inject, since the patient cannot localise the pain with any accuracy.

Weiss and Davis record in their paper observations on two normal subjects in whom localised pain was produced by distending the œsophagus with a balloon. Infiltration of skin with novocain in the region of the pain produced migration of the pain, with relief in the infiltrated area. It is not possible to criticise these observations satisfactorily, since such details as the dimensions of the apparatus used are not given. But it appears possible that the localised pain may have been due to pressure exerted through the walls of the œsophagus upon some branches of the intercostal nerves. Whatever the explanation may be, their results from these two cases are of much less significance than those already discussed, and cannot be held to invalidate the conclusions at which we have arrived.

Summary.

(1) In patients with *distinctly localised* abdominal pain subcutaneous infiltration of the painful area with novocain causes complete or partial relief of pain. (2) The contention that these observations afford direct experimental support for the viscero-sensory reflex theory of referred pain is criticised. (3) In patients with shoulder-tip pain from irritation of the peritoneum under the diaphragm, subcutaneous infiltration of the area in which the pain is felt causes complete or partial relief of pain. (4) These observations afford strong evidence in favour of the peritoneo-cutaneous radiation theory of referred pain as opposed to the viscero-sensory reflex theory.

THE USES OF CHLORETONE.*

BY W. ESSEX WYNTER, M.D.,
F.R.C.P. LOND., F.R.C.S. ENG.,
CONSULTING PHYSICIAN TO THE MIDDLESEX HOSPITAL.

I HAVE been fond of quoting a saying by a French physician that "what impresses one's colleagues is a correct diagnosis, what impresses the relatives is a good prognosis, but what impresses the physician himself is when any definite effect results from his treatment."

I want to say something about a comparatively new drug, which I believe to be the most potent remedy for several disorders hitherto treated by palliatives with but slight success. It may seem surprising to allude to a drug as new, which I have employed for perhaps a quarter of a century, but it is not yet old enough to be admitted to the Pharmacopœia and consequently is unknown to many. The drug is chloretone—chemically trichlor tertiary butyl alcohol, and physically a white coarse powder with a rather acrid taste, volatile and sparingly soluble in water, like camphor. It first came under my notice as a preservative in Parke Davis's solution of adrenalin. I employed this in the treatment of some cases of gastric ulcer, or rather erosion, to arrest hæmorrhage and was struck with the disappearance of the pain, hunger, and restlessness which ensued. This could hardly be attributed to the adrenalin, and later when I gave the chloretone alone I found that the effect was enhanced. It acted as an anodyne as well as a preservative—not only locally but as a general sedative when the dose was increased. Following this observation I was led to employ chloretone in a number of affections in which these attributes promised to be useful.

Sea-Sickness, Chorea, and Tetanus.

Perhaps the first trouble in which the anæsthetic and sedative effect of chloretone was employed was in the prevention of sea-sickness. So many means had been recommended before without success that the general public regarded with absolute incredulity any idea of a preventive or remedy in such circumstances. I am, however, quite convinced that, given a start of half an hour, five grains of chloretone will enable a person to complete a voyage of anything up to six hours without discomfort on the score of sea-sickness. This same applies to travelling by train or air which affects some people in the same way.

I recall an instance of a French lady who taught French in England and English in France and crossed the Channel perhaps four times a year. She was evidently a poor sailor, for she never escaped sea-sickness or expected to even on a calm day. I gave her some 5-grain powders of chloretone, and she made her first crossing in perfect comfort. Unfortunately, however, the spare doses had been wrapped in ordinary paper, and on the return journey, owing to evaporation, all had disappeared, and mal-de-mer asserted itself as before. The drug was later put up in gelatin capsules, and remaining available enabled her not only to accomplish the passage without upset, but even to go by the long route.

In another instance the journey to South Africa was accomplished—a matter of 18 days—by a judicious repetition of the dose.

I only mention these two early experiences for since then proprietary articles under the name of Zotos and Mothersill in which chloretone is the effective constituent have been advertised and widely used.

The sedative effect on the brain, indicated in these instances, suggested to me the probable value of the drug in chorea, which is dependent on disturbance originating in the cerebral cortex. In our archives is included a collection of 100 such cases treated only with chloretone. They were of varying intensity, age, and duration, just as admitted, and I will only quote you the final analysis which showed that the choreic movements were suppressed in an average of five days and the stay in hospital reduced to three weeks. This not only represents a marked reduction in the duration of the illness, but in addition an immense saving in nursing and the suffering of the patient by injury and loss of sleep and food through the violent and ceaseless movements. In these cases the chloretone was given in five or ten-grain doses dissolved in paraffin or cod-liver oil emulsion, and this larger dose continued over several days disclosed further effects of the drug, two of which I will mention as leading to wider uses. Full doses led to a condition of stupor resembling that present in encephalitis lethargica, in which the patient apparently slept day and night and required to be roused to take food—not, you may think, a desirable consummation, but a very blessed contrast in severe cases to the violent contortions and need for constant restraint to keep the patient in bed or from physical injury. The administration of the drug in moderate or small doses caused insensitiveness of the bladder amounting in some to retention of urine. Now this sedative effect on the central nervous system and bladder find useful application in other directions.

On one occasion, returning from the summer vacation, I found a boy in the ward suffering from tetanus. In spite of treatment he was having seizures every hour and the outlook was as hopeless as is usual in these cases. Recalling the effect of chloretone on some of the severer cases of chorea, I administered at once in an enema 20 grains dissolved with the aid of glycerin. He had one seizure only soon after, and then made a complete recovery. As you know, tetanus is fortunately not common, and I never had another opportunity of testing the remedy; but I am glad to put this on record as I have seen accounts since of fatal cases not treated in this way. If it only controls the symptoms it may give time for other remedies to act, which at present they have little chance to do.

Vesical Irritability: Whooping-cough.

With regard to the effect on the bladder, we have been used to the employment of buchu and hyoscyamus with inconspicuous results, though frequency of micturition is a very distressing condition. Even in average health an irritable bladder causes much inconvenience, and often entirely debars people so afflicted from social engagements. I once enabled the chairman of a medical meeting to get through a long morning while suffering from diarrhœa by giving him a teaspoonful of raw arrowroot, and I am sure that the practitioner who enables a patient to weather a lunch or tea party without inconvenience by the use of a five-grain capsule of chloretone will earn eternal gratitude.

I now come to small doses, the basis being a saturated solution in water (grs. 2½ to the ounce) comparable to camphor water. This solution with two drachms of 1–1000 adrenalin solution to the ounce proved of the greatest service in hundreds of cases of conjunctivitis resulting from irritant gas during the late war, subduing the irritation and reducing the hyperæmia. At the same time the escape by way of the lacrymal duct led to some loss of sensation in the nose and pharynx. Later this side issue suggested the use of chloretone in hay fever. Inhaled as a spray from an atomiser the solution immediately allays the symptoms, the effect lasting many hours, so that occasional repetition will carry the patient through the usually distressing period of early summer. As an anti-spasmodic in acute gastric flatulence, dysmenorrhœa, persistent hiccough, or the severe pain of shingles its effect is immediate and sure.

All this will hardly be believed, but it may be observed that none of the maladies referred to has responded to specific or known remedies; so one has quite a free hand to try something fresh. Having now perhaps strained credulity to the utmost, I will conclude by making the most outrageous statement of all—namely, that this dilute solution of chloretone in doses of one grain will cure whooping-cough in a week. I was recently consulted about a little girl of 3 causing great anxiety to her parents owing to vomiting, sleeplessness, and rapid wasting resulting from the frequent violent paroxysms. One-grain doses of chloretone were given four times a day with immediate relief. After two days it was given only morning and night, and after the fifth day discontinued altogether as there was no further need, and there was no recurrence.

---

ACUTE DISSEMINATED ENCEPHALOMYELITIS FOLLOWING VACCINATION.

BY CECIL D. COYLE, M.B. N.U.I.,
ACTING MEDICAL SUPERINTENDENT, MILE END HOSPITAL
AND
E. WESTON HURST, M.D. BIRM., B.Sc.,
RESEARCH PATHOLOGIST TO THE MILBANK FUND FOR POLIOMYELITIS RESEARCH, BACTERIOLOGICAL DEPARTMENT, LISTER INSTITUTE OF PREVENTIVE MEDICINE.

AN unusual opportunity for continuous observation during life with a complete autopsy 17 hours after death makes this fatal case of so-called post-vaccinal encephalitis worthy of record.

The patient, a female aged 5, unvaccinated, who lived in Limehouse, was admitted to Mile End Hospital on June 1st, 1929, with pneumonia of four days' standing. She had had measles and chicken-pox in infancy, and in 1927 had an attack of pneumonia which left her with a "weak chest," for which she had since attended Victoria Park Hospital.

Her temperature was 103·6° F. The lungs showed a catarrhal pneumonia chiefly affecting the right middle lobe, but the heart and abdomen showed no abnormality. Two days later both upper lobes were involved, the child was very delirious, and meningism was noted. The fever settled by lysis by June 11th and convalescence was uneventful, the physical signs in the chest clearing rapidly. She was about to be discharged from hospital when, on June 23rd, another child, admitted to the ward on the previous day, developed the rash of small-pox. As a result, the infected ward was put in quarantine, and on June 26th 15 contacts, nurses and children, were vaccinated. The same batch of Government lymph was employed for all these vaccinations, two insertions being made in the left arm and half a tube of lymph (undiluted) being used in each case.

The patient had a temperature of 100° on the fifth day after vaccination and an evening temperature above 99° on the seventh and ninth days; thereafter the temperature was normal until the evening of the thirteenth day (July 9th). During this period the child appeared well and lively.

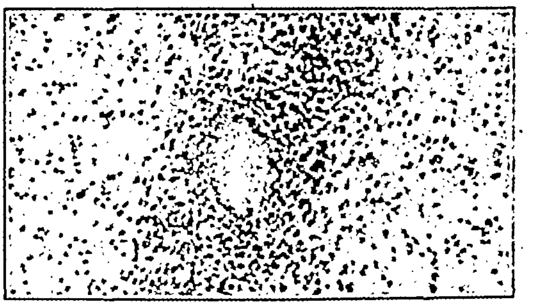
About bedtime on the evening of the thirteenth day the child was noticed to be rather excited, running about and striking other children. Her temperature was 100°, but she was not complaining. She was put to bed and given an aperient. The following morning she complained of headache and pain in the limbs. Her temperature was then 101·6°, pulse-rate 110, and respiration-rate 24. She passed urine naturally about this time. At noon the child told the nurse that she had wetted the bed; this was the only occasion on which she was incontinent. Fifteen minutes later she had become drowsy, though easily roused: her face was flushed and examination of the throat was negative. At 4.30 P.M. she accepted a drink; this was the last time she spoke or took food. It was now noticed that a stream of saliva was running from her mouth.

When examined at 5.45 P.M. she was lying on her back with the head turned to the right and saliva running freely. The face was grey, with slight cyanosis, and the cheeks were puffy, although the parotids were not palpably enlarged; she was very drowsy and difficult to rouse. There was ptosis of the right upper eyelid; the pupils were round, central and equal, and contracted briskly to light. Reaction to accommodation could not be tested. There was no squint or nystagmus. The fundi showed dilated veins in the neighbourhood of the discs but were otherwise normal. The neck muscles were stiff but there was no head retraction. The cheeks gave slight muscular response to pin-prick, more marked on the left side; there was occasional slight twitching of the left angle of the mouth, doubtful weakness of the right side of the face, and definite weakness of the right arm and leg. The abdominal reflexes were sluggish, especially the lower ones. The knee-jerks and ankle-jerks were brisk and there was bilateral ankle-clonus, not well sustained. The plantar response was extensor with all the toes on both sides, and Kernig's sign was present on the left side. Tache cérébrale was present. There were two vaccination crusts, half an inch in diameter, in the left deltoid region, with a slight surrounding fading redness. No glands were palpable in the left axilla, nor was there general enlargement of lymph glands. The heart, lungs, and abdomen showed no abnormality.

Eight ounces of urine were removed by catheter; it contained a trace of albumin but there was no organised deposit. A culture grew *B. coli communis*. Lumbar puncture was performed under light anæsthesia and 40 c.cm. of clear, colourless fluid dripped away. This contained 0·8 small lymphocytes per c.mm.; it gave normal reduction and there was no increase of protein.

The drowsiness became steadily deeper during the evening, passing into coma. When seen the following morning (July 11th, fifteenth day) the child was deeply comatose and there was still ptosis. The pupils reacted briskly to light, ptyalism had ceased, and the tongue pointed to the right. There was now no difference in the muscular power of the two sides of the body, but the tone of the limb muscles was diminished. The knee-jerk was absent on the right side and just present on the left. There was no ankle-clonus; the right plantar response was definitely flexor and the left gave a doubtful Babinski. The temperature was 101·4°, the pulse-rate 140, and the respiration-rate 68. The child was again catheterised, though the bladder was not distended.

FIG. 1.



Low power view of a vessel of the subcortical white matter showing dense extra-adventitial infiltration.

At 5 P.M. her colour was much worse. Cheyne-Stokes respiration was established and muco-pus, which collected at the back of the throat, was brought up from time to time. She was sweating profusely. Otherwise the physical signs had not altered.

At 6 P.M. the temperature was 102·4°, the pulse-rate 160, and the respiration-rate 62. The pupils were still small, round and equal, but they now responded very sluggishly to light. Lumbar puncture was again performed and 45 c.cm. of clear, colourless fluid dripped away. However, there was no improvement and she died at 7 P.M. Her bowels had acted on July 9th; from then on she was constipated.

It is noteworthy that the only other person who showed unusual signs was a girl aged 5, previously unvaccinated, who had been vaccinated with the other half of the same tube. This child was convalescent from furunculosis of the right external auditory meatus. She had previously suffered from chicken-pox and measles. On the fifth day after vaccination her evening temperature rose to 100°, and there was an evening rise above normal on the seventh, eighth, ninth, tenth, thirteenth, and fourteenth days. During this period the child appeared to be quite well. On the morning of the fifteenth day she vomited and her temperature rose to 102°; she was definitely drowsy. She was cold-sponged, and when seen at noon her temperature was 103°, although she was no longer drowsy and no abnormal physical signs could be made out. The fever subsided next day and nothing further ensued. When seen again in October, 1929, she was quite well.

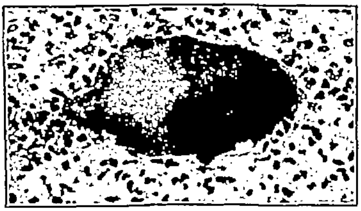
Autopsy.

The only macroscopic abnormality of the nervous system was intense congestion of the small vessels of both grey and white matter. The bulk of the brain was fixed in 10 per cent. formol-saline; after embedding in celloidin, sections were stained with hæmatoxylin and van Gieson and by Nissl's method, while frozen sections were stained for fat and by the Bielschowsky method for neurofibrils. Tissue fixed in formol bromide was utilised for Penfield's modification of Hortega's method for microglia. Zenker-fixed material was embedded in paraffin and stained by Giemsa and Panchrom. Finally, tissue was mordanted and stained by the Weigert-Pal procedure for myelin sheaths.

Character of Lesions.—In stained sections the lesions can quite easily be seen with the naked eye. In the white matter the changes occur in strict association with the blood-vessels, of which some are affected and some escape in any given area; in the grey matter this association may not at first sight appear obvious. The essential lesions are: (1) perivascular infiltration, and (2) extra-adventitial infiltration with demyelination of the area immediately surrounding the vessel. Perivascular infiltration, consisting of a collection of inflammatory cells in the Virchow-Robin spaces, varies in degree in different vessels. In some only a few scattered cells are present; in others a cuff, several cells deep, extends round the whole circumference of the artery or vein. The constituent cells are mainly large and small lymphocytes with a few plasma cells and, in some regions, occasional polymorphonuclear leucocytes. Extra-adventitial infiltration (i.e., a collection of cells in the nervous tissues immediately outside the vascular adventitia) is associated with and is presumably the reaction following destruction of the myelin sheaths over a wider or narrower zone around the vessel. Where closely adjacent vessels are affected their respective zones of infiltration and demyelination may coalesce. As is clearly seen in sections stained by Penfield's method, the majority of the cells of this infiltrate are microglial in nature; in sections stained by the Nissl method their cell-bodies, irregular in outline, appear reticulated or finely vacuolated. Appropriate methods show them to contain numerous fine fatty granules, but typical fully formed granular corpuscles are wanting. The nuclei of these cells are very polymorphic and assume a *great variety of grotesque forms; some have* to be distinguished from polymorphonuclear leucocytes, to which they bear a superficial resemblance. Glial cells, some with slightly enlarged bodies and others with large pale nuclei, are also present. Where the perivascular infiltrate is very dense there may be some overflow of lymphocytes into the immediately adjacent nervous tissue; in many areas a few polymorphonuclear leucocytes are mingled with the other infiltrating cells and may be found at some distance from the vessel wall. Occasional wander cells are present. Among all types of cells nuclear degeneration in the form of pyknosis and karyorrhexis is very common and nuclear debris is abundant in almost every region.

While in the white matter the limits of the extra-adventitial infiltrate are more or less sharply demarcated at a level where demyelination ceases, in the cortex and other areas of grey matter this infiltrate appears to be less dense but more extensive, and its peripheral limits are hard to define. Such areas cut tangentially appear to be unconnected with the vessels and suggest a localised overgrowth of microglia; many sections may have to be cut before the affected vessel comes into view. Weigert-Pal preparations show that, here as elsewhere, destruction of such myelinated fibres as may be present has occurred. In sections stained by the Weigert-Pal method the zones of perivascular demyelination are well demonstrated. In some cases the process is complete, but in others fragments of the sheaths originally present are still visible and stain more intensely than the normal myelin. At the periphery of the demyelinated area the persisting myelin sheaths are greatly distorted or ballooned and globules of free myelin are more numerous. The amount of free myelin, however, together with that of the fatty products of its degeneration seen in hæmatoxylin and Scharlach preparations, does not nearly correspond to the extent of the demyelination; there is also a striking absence of anisotropic substances in the fully demyelinated areas, and it seems that not only is the removal of waste fatty products accomplished with abnormal rapidity but that much of the myelin disappears without breaking down into the doubly refractile lipoid materials seen in the slower process of tract degeneration.

FIG. 2.



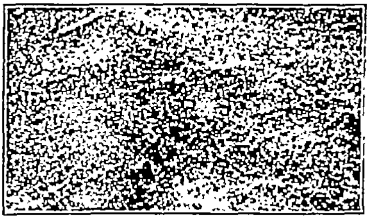
High power view of a less severely affected vessel to show the polymorphic appearance of the infiltrating microglial cells.

Even in the zones of complete demyelination a number of axis-cylinders persist, although the total is far below the number normally present. Of those which remain many are thickened and stain more intensely than normal, while fusiform swellings are present at intervals along the course of others. The nerve-cells are everywhere surprisingly well preserved; even when involved in a dense extra-adventitial infiltration their appearance is little altered. Thus in the medulla the lesions are almost unilateral and, while the cells of the twelfth nerve nucleus of one side are quite normal, on the other side they are involved in an extensive zone of infiltration and myelin destruction: even so, they show only minor changes in the form and colorability of their Nissl bodies.

Distribution of Lesions.

Cerebral Hemispheres.—Lesions are numerous throughout the white matter, in the cerebral cortex, and in the grey nuclei at the base; all of the many areas examined show some affected vessels. Both arteries and veins are involved, but in some regions particularly the latter. Perivascular infiltration may exist in the cortex in the absence of extra-adventitial changes, but elsewhere it is associated with the characteristic perivascular demyelination. Small hæmorrhages into the demyelinated areas are sometimes seen; no reaction is seen in the surrounding tissues, a fact which suggests that they occurred shortly before death or that they may possibly be attributed to rupture at autopsy of the greatly congested vessels. In a few places, particularly in the deeper parts of the sulci, the meninges contain small collections of inflammatory cells similar to those in the perivascular spaces.

FIG. 3.



Weigert-Pal preparation of spinal cord, showing zones of demyelination around the vessels radiating through the white matter.

Cerebellum.—Numerous vessels in the white matter show perivascular infiltration and zones of demyelination.

Brain-stem.—Severe in the midbrain and pons, the changes increase to a maximum in the upper part of the medulla, then decrease in intensity as the cord is approached. At all levels they are very much more marked on the right side; the central parts of the substantia reticularis and the grey matter in the floor of the ventricular system are severely involved. *Perivascular infiltration is often intense and the* extra-adventitial zones of adjacent vessels often coalesce. Arteries and veins alike are affected. The meninges are normal.

Spinal Cord.—A feature of the disease in the cord is the severe involvement of one segment and the entire freedom from lesions of a closely adjacent segment. Thus, while the first cervical segment is quite normal, the third cervical shows severe changes; the first lumbar segment is severely involved and the last lumbar segment and sacral region are free from disease. A second and unusual feature at almost all levels is the striking limitation of the lesions to the right half of the cord, the other being wholly or almost wholly spared; at the same time the grey matter in many segments is more severely affected than the white. In the middle and lower cervical, upper dorsal, and upper lumbar regions the unilateral distribution of the lesions is absolute. The vessels radiating through the white matter, particularly of the anterior and lateral columns, show considerable perivascular and extra-adventitial infiltration with a wide zone of perivascular demyelination. The large vessels of the grey matter are similarly affected and there is considerable diffuse infiltration of the anterior or posterior horns or both. There is a narrow zone of demyelination at the surface of the cord in the lateral column. The meninges are normal. In the lower dorsal region the lesions, though more marked on the right side, are not absolutely confined to it; on the left side the lesions affect only the white matter, while on the right side both white and grey matter are involved. There is considerable perivascular infiltration of the vessels of the anterior fissure, with a narrow zone of demyelination along both lips of the fissure.

Intervertebral Ganglia and Peripheral Nerves.—No changes were detected in the lower cervical ganglia or brachial plexus of either side.

Other Organs.—The lungs, which macroscopically were greatly congested, show numerous small areas of early broncho-pneumonia. The axillary lymph glands on the left side show an inflammatory reaction of moderate degree. The heart, liver, spleen, pancreas, kidneys, submaxillary and parotid glands, stomach, and intestines appear normal. One calcified lymph gland was present in the mesentery. The vaccinated area appeared normal for the period following the inoculation; there was no sign of sepsis and the blood was sterile on culture.

The clinical picture presented by this fatal case of encephalomyelitis is in accordance with the descriptions of similar cases occurring after vaccination published by Turnbull and McIntosh (1926), Bijl (1928), Rivers (1929) and others, and with those cases following acute infectious diseases—e.g., measles (Greenfield, 1929), or occurring spontaneously (Brain and Hunter, 1929). The overwhelming character of the infection was very striking. Rivers notes two instances in which, after vaccination, two children in the same family developed the symptoms of encephalomyelitis on the same day. It seems possible that the second of our cases may have had an abortive attack of encephalitis, although there is no apparent reason why this one tube of lymph should have contained anything not present in the rest of the batch.

Of the remaining 13 individuals vaccinated, two were children, aged 5 and 4 respectively and previously unvaccinated, who had recently recovered from pneumonia. In them, vaccination produced no unusual effects. In all the cases a "brisk take" was noted on inspection on July 3rd. At no time did the vaccinated arm in the fatal case differ in appearance from the arms of the others vaccinated.

Histologically the lesions in the present case conform closely to the descriptions given by Turnbull and McIntosh (1926), Lucksch (1926), Bouman and Bok (1927), Perdrau (1928) and others, of the disseminated encephalomyelitis which has during recent years occurred from time to time as an early sequel to vaccination. An unusual feature of the present case, and one to which we have been unable to find reference in the literature, is the almost complete limitation of the cord lesions to one-half of the cord. In view of the alleged direct association between vaccinia and the nervous disease, it is perhaps a not unimportant fact that it was the right half of the cord which was affected—whereas vaccination had been performed on the left arm—and that no lesions were detected in the brachial plexus or intervertebral ganglia on the vaccinated side. In their essential characters the lesions do not differ from those in the similar cases following measles (see Greenfield, 1929) and certain other infective states, or arising during the course of antirabic treatment; one of the writers (E. W. H.) is at present investigating such a case, to be published shortly, occurring after small-pox. Any investigation into the ætiology of this "post-vaccinal encephalitis" must therefore take into account the occurrence of similar complications in the other acute infective fevers and aim at discovering a common factor responsible for the production of identical histological lesions in a number of very different conditions.

We are indebted to Dr. R. L. Guthrie, coroner for East London, for permission to publish this case.

Clinical and Laboratory Notes.

DILATATION OF THE AURICLES RESULTING FROM HEART-BLOCK

AND PRODUCING PRESSURE SYMPTOMS.

BY ALBERT A. FITZGERALD PEEL, D.M. OXF.,
ELECTROCARDIOGRAPHER, VICTORIA INFIRMARY, GLASGOW;
PHYSICIAN TO THE OUT-PATIENT DEPARTMENT,
BELLAHOUSTON DISPENSARY, GLASGOW.

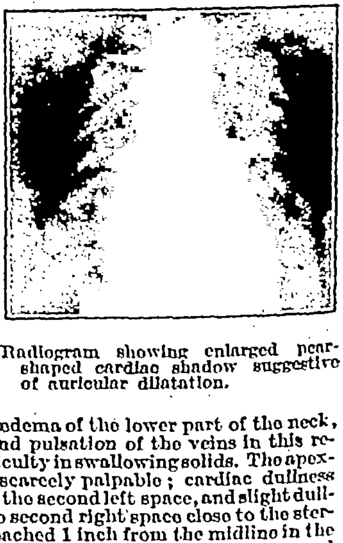
IN THE LANCET of Dec. 12th, p. 766, F. J. Bach and T. S. Keith describe a case of enlargement of the left auricle causing pressure on, and obstruction of, the left main bronchus and quote a series of cases described by various authors. Pressure on the œsophagus and paralysis of the left recurrent laryngeal nerve have also been described as rare complications of auricular dilatation. The case now described is of interest from two points of view; for in the first place it affords an example of dilatation of the auricle producing pressure symptoms of such a nature that a mediastinal tumour was suspected; and secondly, it illustrates a mechanism whereby auricular dilatation may be produced apart from valvular lesions and apart from auricular fibrillation, the two most commonly recognised causes. Inasmuch as the patient did not succumb, post-mortem confirmation of the findings and conclusions is lacking, but the clinical and instrumental findings appear sufficiently clear to warrant the conclusions drawn.

Report of the Case.

A. B., aged 48, was a healthy man until the onset of his present symptoms; he had never had acute rheumatism, chorea, or sore-throats, and had not previously suffered from cardiac symptoms. His family history was negative. About January, 1929, he began to have dyspnœa on exertion and cough, with occasionally slight œdema of the ankles at nights. In March he began to have difficulty in swallowing solid food, and stated that his voice had altered in character; he noted that the lower part of his neck was much swollen. He was sent into hospital with a tentative diagnosis of mediastinal tumour.

On admission his lips were cyanosed: there was no œdema of the legs. His speech was normal, and there was no evidence of laryngeal paralysis. There was considerable œdema of the lower part of the neck, and marked distension and pulsation of the veins in this region. He experienced difficulty in swallowing solids. The apex-beat was not visible and scarcely palpable; cardiac dullness was increased upwards to the second left space, and slight dullness was also noted in the second right space close to the sternum; the right border reached 1 inch from the midline in the fourth space, but only ¾ inch in the fifth space, the normal angle between the right border of cardiac dullness and the upper border of hepatic dullness being maintained; the left border was 4½ inches from the midline in the fifth left space. The sounds were infrequent (40 per minute), with occasional extrasystoles; a third sound could be heard periodically during the diastolic interval, sometimes occurring early, sometimes in mid-diastole. The sounds were faint at all areas, almost inaudible at the aortic; no murmurs were heard in any area; the second sound at the pulmonic area was relatively accentuated and intoned. The pulse was regular apart from occasional extrasystoles, and of moderate volume; the volume in the left radial was slightly less than

FIG. 1.

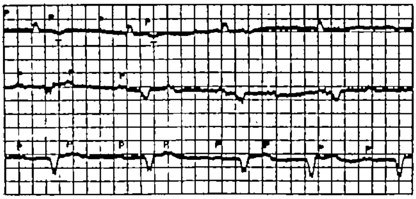


Radiogram showing enlarged pear-shaped cardiac shadow suggestive of auricular dilatation.

in the right; the arteries were not palpable and the blood pressure was not raised. Apart from occasional rhonchi at each base the lungs were normal. The liver and spleen were not palpable, and there was no albuminuria. The pupils were equal.

The Wassermann reaction was negative. A radiogram of the chest (Fig. 1) shows an enlarged, "pear-shaped" cardiac shadow suggestive of auricular dilatation; there is no evidence of a mediastinal tumour nor aneurysm. An electrocardiogram (Fig. 2) shows an auricular frequency of 86 with slight sinus irregularity; the P wave is broad and notched resembling that seen in mitral stenosis. 2–1 block is present throughout the portion of the tracing shown in the diagram, the ventricular rate being 43, but a further portion of tracing showed occasionally two successive auricular beats reaching the ventricles; another occasional feature was the occurrence of left ventricular extrasystoles in pairs. The ventricular responses show changes characteristic of a further intraventricular block, approximating to a complete block of the right branch of the auriculo-ventricular bundle. The total duration of ventricular systole is prolonged occupying 0·52 sec.; the P–R interval in those beats in which auricular contractions excite ventricular responses varies from 0·2 to 0·4 sec.; thus it comes about that the total duration of cardiac systole (from the commencement of P to the termination of T) varies from 0·72 to 0·92 sec.; and since the interval between successive auricular beats averages approximately 0·7 sec., alternate auricular beats occur before the termination of the preceding ventricular systole in the majority of cycles. The significance of this feature will be referred to presently.

FIG. 2.



The electrocardiogram.

Course of Illness.—With the lapse of time and confinement to bed the patient's symptoms gradually improved, and four weeks later he was feeling comfortable in bed; he no longer had dysphagia; the œdema of the lower part of the neck had entirely disappeared, and the distension and pulsation of the veins was very much less noticeable. In the condition of the heart itself no change was noted; an electrocardiogram showed the same features as before, with an auricular rate of 98 and ventricular rate of 49; there were still occasional extrasystoles in pairs, but now of right ventricular instead of left ventricular origin. After another three weeks he was allowed up gradually, and in another month he was able to go home; he was able for mild exertion without much dyspnœa but still had occasional slight œdema of the feet at night if he stayed up too long; the cardiac dullness remained unchanged, the sounds had improved slightly in intensity, but the block was still present; the pressure symptoms had entirely disappeared.

Comments.

Apart from the transient dysphagia which was presumably the result of pressure of a dilated auricle on the œsophagus, this case is of interest in view of the mechanism whereby the auricular dilatation appears to have been produced. Dilatation and hypertrophy of the left auricle as a result of mitral stenosis is well recognised; in Bach and Keith's case the physical signs during life were those of mitral stenosis, and although there was no narrowing of the mitral orifice post mortem—in fact, it was actually widened—the changes described as shown by the mitral cusps and chordæ tendineæ appear to be those of an early stage in the development of a certain type of stenosed mitral valve, and are at least suggestive of a considerable degree of mitral incompetence. Apart from valvular lesions, dilatation of both auricles is the rule in auricular fibrillation and in many cases of auricular flutter, where effective contraction of the auricles has ceased, and the chambers become passively distended. The present case, however, illustrates yet another possible mechanism, for it has been shown that every second auricular beat (with occasional exceptions) occurred before the termination of the preceding ventricular systole; on these occasions the auricles must fail to empty their contained blood into the ventricles, and they are consequently full of blood at the commencement of the succeeding diastole; during this diastole they must become overfilled—particularly in the case of the left auricle if the output of the right ventricle remains effective. In due course, if the condition continues, auricular hypertrophy is likely to follow, and once this has occurred the diastolic overfilling will be lessened. Thus the accentuated pulmonic second sound, the broad notched P of the electrocardiogram suggestive of auricular hypertrophy, the occurrence of pressure symptoms, and their ultimate disappearance can all be explained as the result of the heart-block; the latter in this case can only be ascribed to myocardial degenerative changes resulting from disease of the coronary arteries.

It must be pointed out that in order to explain the facts as above the essential feature is, not the presence of heart-block, but the occurrence of a relatively large proportion of the auricular beats at a time when the ventricle is actually contracting. There are other disorders of cardiac rhythm in which this condition may be fulfilled—e.g., certain cases of parasystole—and on the other hand, by no means all cases of heart-block—or even of 2–1 block fulfil the requisite conditions. In an ordinary case of 2–1 block, where the ventricular systole is not unduly prolonged and where the P–R interval of the effective auricular beats is not greater than 0·2 sec., the total duration of a cardiac cycle will not exceed 0·52 to 0·6 sec.; unless the auricular beats follow one another at intervals of less than 0·6 sec., therefore, the alternate beats will not occur before the termination of the preceding ventricular systole; that is to say, unless the auricular rate exceeds 100 per minute the conditions will not be fulfilled. To enable the conditions to be fulfilled with a lower auricular rate, there must be, in addition to the 2–1 block, either a prolongation of the P–R interval of the effective beats, or a prolongation of the duration of ventricular systole (RST period). Similar considerations may be applied to other grades of block and to other disorders of rhythm.

I am indebted to Dr. Ivy McKenzie for permission to publish the case, and to the superintendent of the Victoria Infirmary for permission to reproduce the radiogram.

A NOTE ON THE TREATMENT OF NEURASTHENIA.*

BY A. W. HENDRY, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ABERDEEN ROYAL INFIRMARY.

THE purpose of this paper is to suggest a simple provisional plan for dealing with neurasthenic states. Life, it has been said, is the continuous adjustment of internal relations to external relations. In the mental sphere suitable adjustments depend on adaptability, and if adaptability be deficient or defective appropriate adjustments cannot occur, hence conflict and mental disharmony. Adaptability is largely a constitutional characteristic depending on the predetermined disposition of the brain. Where the predominating feature of a mentality is affective tone, there must follow a tendency to emotional states without which the neuroses could not occur. This tendency may occur in a mind otherwise normal;

---

* Based on a lecture delivered to the Aberdeen University Post-Graduate Society.

it results simply from a high degree of the affective component. It may also occur in a mind below normal. Neurasthenia is as common in persons highly endowed as in persons below normal. Wherever the feelings get the better of the critical powers, wherever adaptability is deficient or defective, there must result a soil suitable for the growth of functional nervous diseases. Although it is generally accepted that a neuropathic tendency is constitutional, we should remember that, just as good soil becomes poisoned or tired, so the normal constitution under toxic conditions or fatigue may become deteriorated and susceptible to neurotic ailments. We can imagine circumstances which would render neurotic the strongest, the most stable mind. Neurasthenia, then, is a condition depending on a predominating emotionalism, a susceptibility which may be congenital or acquired.

How the Neurasthenic State is Induced.

The determining cause is any circumstance, real or imaginary, which conditions an unpleasant and unacceptable emotion. The adequate stimulus varies with the susceptibility to neurasthenic states. If the susceptibility be slight, the adequate stimulus must be considerable; if the susceptibility be great, the adequate stimulus need be but slight. Neurasthenic susceptibilities are like explosives; it takes a flame to explode one, a spark may explode another, while some explode spontaneously. Pleasant emotions are always acceptable; they cannot determine neurasthenic states. There always exists in neurasthenia some unpleasant and unacceptable emotion. One man hears of his financial ruin. He accepts, perhaps with sighs, his return to poverty and hard gruelling work; he sells his house and his cars, and discharges his servants. He says to himself, "Hard luck!" and as he clenches his hands and sets his jaw, he continues "Ah, well, its no good crying. I'll just have to make the best of things. I'll start again. I'll make good again." This man is no neurasthenic, he has accepted the misfortune and adapted himself to his altered circumstances. His mental digestion is equal to the unpalatable task. Another man hearing of his financial ruin is stunned and drops into a chair. Holding his head in his hands he rolls about and moans and groans. Sleep has deserted him; appetite is gone; his friends have forsaken him; the world has crushed him: he is misery personified. In despair he turns to his doctor, who may prescribe a stomachic and tell him that his stomach is out of order. He miserably carries on and his stomach does not improve; he begins to dread cancer, gets X rayed, has a fractional test-meal, has his stool examined, and generally ends in a worse state than ever. This man has not adapted himself to his environment; he has not accepted the unpleasant fact. This creates a mental state outside his mental entity. There is a foreign body in his mind. The uninvited, unpleasant, and persistent guest is kept at the door, where he creats a disturbance and corrupts all other visitors and thus multiplies the discomfort. The unpalatable body should have been swallowed and digested. The uninvited guest should have been asked in, and the differences settled.

The first step in a neurasthenic state is emotionalism. The unpleasant state cannot be entertained yet cannot be forgotten. The mind becomes preoccupied. This preoccupation has two results: (1) All stimuli are tainted according to the preoccupation; hence dyspepsia becomes cancer, palpitation becomes heart disease—i.e., emotional infectivity. (2) The preoccupation means the inhibition of critical faculties, hence the tendency to accept any statement without criticism; this is increased suggestibility. The sequence, therefore, is emotionalism, preoccupation, emotional infectivity, and increased suggestibility.

The Three Steps in Treatment.

The first point which I stress is, that very careful and sympathetic note should be taken of the numerous complaints. Sympathy and patience will be required, for the patient frequently goes on speaking about his symptoms for an hour or more, and it is the greatest mistake to cut him short. It is of the utmost importance also that notes be taken. There are many medical men who consider this a waste of time and cut the symptom-telling short. These men can never treat neurasthenics with any hope of success. They cannot spare an hour to carry out this absolutely necessary part of the work, but they will waste months in vaguely attempting to do the impossible. The patient should be encouraged to dilate on his troubles, for sometimes the neurasthenic is reticent, and unless you get to know your patient thoroughly—to know his fears, his pleasures, his ambitions, his home life, his habits, and his circumstances you may miss an all-important clue. It is not usually difficult to get him to unburden himself if he has confidence, and I feel very strongly that confidence can be engendered by sympathy, tact, understanding, and a genuine desire to help these patients to recovery. After you have heard his story, repeat it to him; this will keep you right and will also help the patient to appreciate the real interest you have taken in his case. All you have done in this hour is to listen to his story; in reality you have entered into his life, you have got to know him, and he has placed his confidence in you. As a matter of experience I should say you have won half the battle.

At the next meeting, probably a few days later, it is best to subject him to a complete physical examination, an examination which must be thorough and painstaking, each system being taken in turn. You then know his physical state and you increase his confidence in you, but I think it important that on both these occasions you should give nothing away. Assure him that physical examination is a routine affair, and do not attempt to give any interpretation of his symptoms. Your interpretations at this time would probably be wrong and would have to be retracted later; this rather tends to shake confidence.

Your duty is now to associate symptoms and signs; if there be no physical disease then you must analyse his symptoms. Go through them again and you will almost invariably find a common denominator, some unacceptable emotion from which all others are derived. This is usually where experience and knowledge of human nature tells, but it is not a bad rule to be guided by the earliest symptoms. In the case we have mentioned the patient may be seen years after the financial loss; his symptoms might easily be gastric or the wasting might invite thoughts of malignant disease, but the chronological order of symptoms would or should suggest the beginning of his illness. The anorexia would date from that time. The absence of physical signs of organic disease would also indicate a psychopathic disease. Put yourself in the patient's position, assume for a period his mentality and imagine the effect. In fact, I find the easiest way to understand a patient is to imagine I am the patient; it is then usually possible to interpret the symptoms. Distress inhibits appetite; sleep does not come to one who carries a constant mental agony.

The third time the patient is seen I usually find it necessary to ascertain a few matters connected with his symptoms, and by asking a few questions find out whether the general plan of my interpretation is correct. If this be so, then I proceed to unfold the story so that he himself can follow. I take him back to the initial emotional state, indicating how the symptoms occurred and how the others followed, explaining the mechanism as I go along. This does not take very long, usually about half an hour. It is then time to return to the cause under conviction, the original fault, and it will frequently be found that a different presentation of the matter results in its acceptance. Sometimes it is necessary to "predigest" the problem for him. He will then see that he should have acted differently, and nearly always says so. The case is three-parts cured, but the morale remains to be improved by encouragement and persuasion; this is where sympathy and his confidence count for a great deal, for without these he will not respond. With them his morale is enhanced, he will accept unpleasant facts, he will adapt himself thereto. The ruined man resumes means to mend his broken fortunes.

The Time Element.

The treatment takes time; it cannot be done in a day. It may be wise to isolate the patient for a time. Physical therapy is of value as means to an end, and any physical disorder should most certainly receive its proper treatment. In the main, however, the treatment is psychotherapy, a method at present rather in disgrace. Just as the healing knife of the surgeon is a murderous weapon in a villain's hand, so is psychotherapy in the hands of ignorant and unscrupulous persons. In the hands of the physician the methods I suggest can bring nothing but peace and happiness to his patients and satisfaction to himself. It is not suggested that this treatment will cure the predisposition to neurasthenic conditions, but that it will, so to speak, help the patient over a fence in the rough road of life. Curative treatment depends chiefly on prophylaxis. If we could get the child's mind in the plastic stage before predispositions were fixed, then it might be possible so to lessen the tendency to emotionalism that neuroses would not occur.

A SIMPLE METHOD OF TREATING CAVERNOUS NÆVI.

BY G. B. DOWLING, M.D., M.R.C.P. LOND.,
DERMATOLOGIST TO THE WEST LONDON HOSPITAL; ASSISTANT PHYSICIAN IN THE SKIN DEPARTMENT, GUY'S HOSPITAL.

THE treatment of cavernous angioma has always been a rather difficult problem. While the probable spontaneous disappearance of these tumours may be prophesied, for the patients are almost always infants or young children, the majority of parents prefer to have them removed as early as possible.

Application of carbon dioxide snow is ineffective though it will destroy the strawberry mark which often overlies the subcutaneous angioma, and it may even efface an overlying port wine stain. Apart from surgical excision, which is undesirable in an infant, and in some situations impossible, the methods commonly used are:—

1. Application of radium; a reliable method in the earliest cases, but likely to leave a radium scar.
2. Electrolysis with single or multiple platinum points; a painful method necessitating an anæsthetic.
3. Electro-coagulation with a needle electrode; also a painful method, and certain to damage the skin around the parts through which the needle is passed.

It occurred to me, as it has probably occurred to others, that it might be possible to destroy these lesions by thrombosing their contents by means of one of the coagulants used in the treatment of varicose veins. I have treated five cases at the West London Hospital during the past year by injecting the commonly used solution of quinine bihydrochloride and urethane; the result has been very satisfactory.

In the first case, an infant of six months, had two injections at intervals of a week into a small cavernous nævus situated on the back. The child was not brought up to see me for three months, so I was unable to observe its progress, but the eventual result was a complete flattening of the lesion, leaving a small disc of replacement fibrosis in the skin. The next two cases were treated concurrently. In one there was a cavernous nævus situated in the right labium majus; it received three treatments, carried out at intervals of a fortnight, 4 mm. of the solution being injected at a time. This nævus was somewhat shallow, and sloughing at one or two points took place; this, however, gave rise to very little trouble and the result was excellent, all that now remains being flaccidity of the skin over the part in which the nævus was situated. The other case, a cavernous nævus of 1¼ inches diameter on the back, had three treatments; it also disappeared, leaving again a flaccid overlying skin. Finally, two cases of cavernous nævus of the scalp have been treated. These required three treatments each, with the same results as in the former cases—that is, gradual disappearance of the nævus, leaving an overlying, somewhat baggy skin.

About 4–5 minims of the solution of quinine is injected at a time. The needle is passed in near the base of the nævus and about a minim is injected in three or four places. It is probable that many of the lacunar spaces are not reached by the initial treatment, but the immediate effect is an apparent solidifying of the whole nævus. In a fortnight the lesion flattens down somewhat, and the skin over it becomes slightly flaccid. It is then treated in the same way again, selecting parts which appear to have been unaffected by the first treatment. In a fortnight a further degree of shrinking of the nævus is observed, and a third treatment may then be given or it may be left for a few months, and further treatments given if necessary.

I have not treated a cavernous nævus on the lateral aspect of the nose, a common and unfortunate position, because of the possibility of extension of the thrombosis to the cavernous sinus. Although the number of cases that I have so far treated is small, I believe that thrombosis by injection may prove to be the future method of choice.

Reports and Analytical Records.

VINO SAN RAFAEL.

ESPECIALIDAD DE LA SOCIEDAD VINICOLA TARRAGONA. (SPANISH PRODUCE, BOTTLED IN GERMANY.)

THIS rich, red, fruity wine when analysed gave the following results:—

Alcohol by volume	18·24	per cent.
Equivalent to proof spirit	33·0	,,
Total acidity as tartaric acid	0·20	,,
Volatile acidity as acetic acid	0·03	,,
Total extract	23·0	,,
Consisting of—		
Sugar	22·18	,,
Mineral matter, protein, &c.	0·82	,,

The preservatives salicylic, benzoic, and sulphurous acids were tested for with negative results.

The wine, although it has the normal alcoholic content of a port, contains almost three times the amount of extractives. The acidity is low and the wine, whilst possessing a slightly astringent flavour, may be regarded as a pure product, and of value as a tonic.

CANNED FISH.

(1) PONY SMOKED HERRINGS IN TOMATO SAUCE; (2) IVANHOE BRAND SELECTED NORWEGIAN BRISLING; (3) IVANHOE BRAND BONELESS KIPPER SNACKS; (4) FINEST NORWEGIAN SILD.

(THE QUALITY CANNING CO., STAVANGER AND LONDON.)

The following four different kinds of fish were examined—viz., Pony Smoked Herrings in Tomato Sauce, Ivanhoe Brand Selected Norwegian Brisling in pure olive oil, Ivanhoe Brand Boneless Kipper Snacks, and Finest Norwegian Sild in pure olive oil.

—		Pony smoked herrings with tomato.	Brisling in olive oil.	Kipper.	Sild in olive oil.
Total weight of contents of tin		280 g.	111 g.	89·5 g.	114 g.
Weight of fish		200 g.	92 g.	89 g.	98 g.
Percentage of fish in total contents		93	82·9	100	86
Moisture	(per cent.) on drained fish	65·2	50·6	68·8	65·6
Proteins		19·3	19·5	21·6	20·6
Ash		4·0	6·3	1·40	4·7
Fat		11·6	15·7	7·14	9·1
Calorie value per lb. of drained fish		816·6	1025·3	703	767

The different fish were obviously well selected and of good quality. They were clean, palatable, and efficiently sterilised in the packing process. The calorie figures indicate the relative value of these fish as food materials.

GENERAL MEDICAL COUNCIL.

PENAL CASES.

(Continued from p. 1197.)

Alleged Adultery with a Patient.

The Case of Frederick Howard Pratt, registered as of 331, Brownhill-road, London, S.E. 6, M.R.C.S. Eng., 1925, L.R.C.P. Lond., 1925, who had been summoned to appear before the Council on the following charge:—

> "That you abused your position as a medical man by having intimate relations, at your surgery at 80, Standon-park, Lewisham, London, S.E.23, and elsewhere, between May and November, 1928, with a married woman with whom you stood in professional relationship; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The complainant was the husband, who was represented by Mr. J. A. T. Good, of Good and Co., solicitors. Dr. Pratt appeared and was accompanied by Mr. Laurence Vine, instructed by Mr. Denton Rowe, solicitor.

Mr. Good stated that complainant had visited Dr. Pratt for ophthalmic treatment in 1927, and his wife had consulted the doctor a few days later. Violet-ray treatment had been ordered and had been administered, on some occasions by Dr. Pratt's wife. In January, 1928, complainant's wife had consulted the doctor about dyspareunia, and had been given treatment. In March Dr. Pratt had advised consultation and, as he had handed the written address of the specialist to complainant's wife, he had put his arm around her and kissed her. She had not told her husband. On the next day the doctor had again kissed her, and said he had "never felt like that before." On Oct. 14th she had had an operation at St. John's Hospital, and had then been found to be pregnant. It was not suggested that the child was not her husband's. Dr. Pratt had made advances to her on a number of occasions, but had been repelled. The first intimacy had taken place at the surgery in May, and during the doctor's holiday in July she had written to him affectionately. In September Mrs. Pratt had been away and the doctor had invited complainant's wife to his house, where intimacy had again taken place on a couch in the consulting-room. There was no doubt that she had been absolutely infatuated and had pursued the doctor, strongly resenting his attempts to withdraw from the relationship. Intimacy had continued up to three weeks before her confinement. While in the nursing home she had told the doctor that he was not treating her properly, as he was taking up with a nurse. On the last day of 1928, in a local restaurant, she had informed her husband of what had happened. In the evening the complainant and his wife had met the doctor, who had said intercourse had only happened five times, and that all had been over four months before. There had been a scene. The complainant, considering his young baby, had taken the line that the doctor must leave the neighbourhood in a month. Later he had seen the doctor at his surgery, and had left a note saying he would complain to the General Medical Council.

Complainant's wife testified that she had first seen Dr. Pratt in October, 1927, when she had accompanied her husband to the surgery, and later had seen him professionally by herself. She confirmed the account given by complainant's solicitor of subsequent events, and gave details of Dr. Pratt's advances to her. Misconduct had first taken place in the surgery in May, 1928, and had been repeated two or three times a week thereafter. She had written to the doctor at Rotterdam and Antwerp when he was on his holiday, but had never had an answer. He had never suggested discontinuance. She described the visit to the house, a visit to the bedroom, and intimacy in the consulting-room. The last intimacy had been on Nov. 2nd, and the baby had been born on Nov. 23rd. In the nursing home she had told the doctor that she had been informed that the doctor was "hot stuff" and could "not leave women alone, married or single," and that he had taken out a sister at the home. At the interview between the three parties Dr. Pratt had said his wife would probably divorce him, and that he had never cared for witness. He had, in fact, given up his surgery. Witness had seen Dr. Pratt and his wife subsequently. Before making her declaration she had telephoned Dr. Pratt and had gone to see him and talked it over. She had said she would not make the declaration if she could believe that he had ever meant anything he had said. She had suggested that he should undertake the education of the baby, and the doctor had agreed on condition that her husband withdrew the complaint. He had, however, never sent the promise in writing.

Cross-examined, she said she had married in 1926. She had not complained when Dr. Pratt had first kissed her because long before that he had won her sympathy. She denied that she had pursued and waylaid the doctor, writing and telephoning almost daily, or that she made the complaint in a spirit of vindictiveness. She had not behaved like a person deranged after her operation. Every time she had visited the doctor he had asked her to come again. She did not agree that she had been infatuated; she had been in love with the doctor. Dr. Pratt had not remonstrated with her for writing or pestering. She had told him towards the end that she felt he was getting tired and he had only to say so frankly and she would back out. She had not behaved like a distracted woman in the waiting-room. She had never been removed by the police. On one occasion in January she had waylaid Dr. Pratt after a quarrel with her husband; this was the only episode of the kind. She had not gone round to extract money for the education of the child; she had gone to see if he had ever cared at all. Her husband had known nothing about the visit. The support of the child had been the doctor's suggestion in the first place. She had not concocted the story of intimacy because she was jealous and because he would not educate her child.

Re-examined: Up to the time of the present inquiry Dr. Pratt had never denied intimacy. She had never either wanted or received money from Dr. Pratt.

By the Legal Assessor: Intimacy had usually taken place between 9 and 10 in the morning at the surgery, at first always as a result of a message from the doctor fetching her over. The surgery was at the back of the house. They had had an arrangement whereby she rang three times and the doctor opened the door to her. On some occasions the landlady had opened the door. Usually witness had gone straight into the surgery, but on the rare occasions when other patients had been waiting she had gone into the waiting-room. Intimacy had taken place in her house at various times of day in various rooms when she was alone in the house. Her husband had his own business as an iron founder and should be able to afford to educate his child by the time it grew up.

By the President: She had never expected replies to her letters. She had been rather annoyed at the doctor's refusal to take her out in his car.

The complainant identified professional receipts from Dr. Pratt dated October, 1927, April, 1928, and an unpaid account October–December, 1928, including confinement, and related other accounts which he had paid. His wife's mind had been perfectly normal after the operation and always. He described the interview on Jan. 1st, confirming Mr. Good's account of it. Dr. Pratt had said it had not been a question of love but of pure physical attraction. At his private interview with Dr. Pratt, the doctor had remarked that medical students were warned against a certain type of woman. There had been no denial of the intimacy. Subsequently witness had consulted solicitors, had threatened proceedings before the General Medical Council, and had withdrawn this threat at the request of his wife. On April 9th he had written again saying that he proposed to proceed with the complaint, as the doctor had not kept the spirit of their agreement and had been seen about the neighbourhood.

Cross-examined, he admitted that the doctor had told him when he threatened to report him to "get on with it," but did not agree that he had treated both complainant and his wife with contempt. He had never said he was satisfied with Dr. Pratt's explanation. He had noticed that his wife was very unhappy and highly strung after the operation. The doctor had said "as far as clearing out of the neighbourhood is concerned, the surgery does not pay and I have been meaning for some time to give it up." Witness knew nothing of and would not have approved of the suggestion to educate his child. His wife had never suggested withdrawal of the complaint on any such condition. He had not realised how infatuated his wife had been with Dr. Pratt.

By the President: He had heard of the General Medical Council from his cousin, a doctor. He had consulted the solicitor about divorce.

By the Legal Assessor: The doctor's words had been that "it had only occurred five times"; he had not charged the doctor with intimacy, as it had been taken for granted. As the doctor had come in he had said "I understand your wife has told you all about it." The term "intimacy" had never been used.

Mrs. Cokayne testified that she had worked in the house of complainant and had heard the quarrel on Jan. 1st, and had identified the words "Won't you kiss me good-bye?" said by Dr. Pratt.

Cross-examined, she said she had heard voices for more than half an hour but had only heard this one sentence. She was certain these words had been said by Dr. Pratt.

By the President: She supposed the parties had come out into the hall when she had heard this expression.

The Defence.

Dr. Pratt, examined by his counsel, said that he had started practice at the surgery in November, 1925, and was still carrying on practice in the neighbourhood, but had given up the surgery. Complainant's wife had consulted him for pruritus vulvæ, and as this had not responded to Lassar's paste she had been put on sunlight treatment. He described in detail the geography of the surgery to illustrate how little privacy there was there. He agreed that he had usually seen complainant's wife between 9 and 10 A.M., but she had been received absolutely as any other patient and there had been no arrangement of ringing three times. He had never kissed her at any time. During her pregnancy she had visited the surgery about once a fortnight. She had begun to get anxious about her confinement, but he had not noticed anything abnormal towards himself until September. There was no truth at all in her allegation that intimacy had taken place between May and September. The right ovary had been removed and this, together with her pregnancy, had seemed to him to account for her frequent visits and anxiety. Between September and November she had been perpetually at the surgery; it was absolutely untrue to say she had only come at his request. She had started writing letters just before his holiday in July and had written two while he was away. He had been very surprised to see them and had torn them up. He had noticed no abnormal affection for himself. She had accosted him on Christmas Eve as he left his surgery, thanking him for looking after her so well and proffering a petrol lighter as a gift. He had taken this home and shown it to his wife. On the last Sunday in the year the husband had rung him up saying she was in a terrible state of nerves. He had gone round and found her absolutely incoherent and hysterical. He had never seen her like that before and had prescribed valerian bromide. He had been in bed with influenza on Jan. 1st when she had rung up; he had refused to go, but later a new patient had rung up. He had agreed to get up to see the other patient and so had acceded to her second request for a visit. Mrs. Pratt had driven him to the house. He had found complainant's wife in the same excited state. She had said "I've told my husband everything" and that this had included intimate relations with him. He had said "you know that is absolutely untrue." She had wept and he had left. In consequence of a conversation with his wife he had telephoned complainant that evening and had visited him to explain the patient's state and deny the allegations. He had said to complainant "You know that the whole thing is absolutely untrue," and had repeated this to complainant alone. He had never said "it only occurred on five occasions." Complainant had said, "Oh, I could get you turned off the Register. I have a cousin high up in the profession who has influence and who could get you knocked off." Witness had replied "Get on with it then," and had walked out. That evening complainant had rung up to say he was not doing any more and witness had simply put the receiver down. A few days later he had found a note saying complainant was going to report the whole matter to the General Medical Council. About a month later he had met complainant's wife, who had refused to leave him. He had taken refuge in the house of some friends, but she had waited for him and tried to follow him on to a bus and a tram, and he had asked two police-sergeants to see her home. About May she had appeared in the waiting-room; he had asked two other patients to remain outside in the passage and listen to the conversation with complainant's wife. She had proposed that if he would bring up her child as he would one of his own she would withdraw the complaint. He had absolutely repudiated the suggestion and she had become hysterical. Her account of this interview was absolutely untrue. He had never carried on with nurses, nor had complainant's wife ever spoken of it to him. He had not said "Kiss me good-bye," but had probably said "Good-bye." He had never on any occasion had sexual connexion with complainant's wife and had always denied the allegation.

Cross-examined, he said he had torn up all her letters, many of them unread. They had not been professional letters but they had not been love-letters. He had not told the husband because he had put them down to her mental state and had ignored them.

By the Legal Assessor: He had told complainant's wife where he was going on holiday but not when he would be at certain places. She had known how to follow the movements of the ship he was on; it was a definite routine cruise. His surgery was overlooked by several houses; when consulting he had had the curtain drawn.

By the President: He had not asked her to write to him nor had she asked if she might write. She had just said she could find out the movements of the ship. There had been nothing in these letters or in her behaviour to arouse his suspicions of the state of her affections until towards the end of the eighth month of her pregnancy. No reference had ever been made in interviews to the letters. Complainant had not given him a month to clear out; he himself had brought the subject up, saying it was curious that he had arranged to close the surgery.

Mrs. Pratt confirmed the material facts as related by her husband. She had noticed a great alteration in complainant's wife after the birth of the child and had regarded her as deranged. Witness had had experience as a nurse.

Mrs. Hooper testified that she had assisted in the housework at Dr. Pratt's house and had seen complainant's wife there on May 21st. A patient, Mrs. Smith, had been present at that time and they had both been asked by Dr. Pratt to listen to the conversation. She related the conversation, confirming Dr. Pratt's account of it. Complainant's wife had first mentioned the education of the child and the doctor had said "Certainly not." When she came in and when she [illegible] had been very agitated, and she had [illegible] in the road half an hour later.

Cr[illegible] lainant's wife had appeared to [illegible] had not known why the doctor had asked her to listen or why he had said complainant's wife was a dangerous woman. Mrs. M. T. Smith confirmed this account of the interview in all particulars.

Mr. Vine addressed the Council, sketching the case as an example of the lengths to which a neurotic woman would go and pointing out the absence of any corroboration of her story.

Mr. Good argued that a professional man receiving affectionate letters from a woman patient and destroying them was acting suspiciously.

After deliberation in camera, The President announced the decision of the Council as follows :—

"Mr. Pratt : I have to announce that facts alleged against you in the Notice of Inquiry have not been proved to the satisfaction of the Council. The case is, therefore, dismissed."

The Case of Donald McGregor Stewart, registered as of 5, Waunwen, Nantymoel, Glam. ; L.R.C.P. and S. Edin., 1917, L.R.F.P.S. Glasg., 1917, who had been summoned to appear before the Council on the following charge :—

"That you were convicted of the following misdemeanours —viz., (*a*) At the Bridgend Petty Sessions : (1) On Oct. 16th, 1926, of being drunk whilst in charge of a motor-car, and were fined £3 and your driving licence suspended for 12 months ; also of driving a motor-car to the danger of the public, and were fined £1 ; (2) on Oct. 8th, 1927, of being drunk, and were fined 10*s.* ; also of using indecent language, and were fined 30*s.* ; (3) on Nov. 26th, 1927, of using indecent language, and were fined £3 or 14 days ; (4) on June 16th, 1928, of using indecent language, and were fined £2 or 14 days' hard labour ; (5) on August 18th, 1928, of being drunk and disorderly, and were fined £1 ; (6) on May 11th, 1929, of using indecent language, and were fined £3 or 14 days' hard labour ; and (*b*) At the Ystrad Police-court : (7) on June 25th, 1928, of using indecent language, and were fined £3."

Mr. Stewart appeared in answer to his notice.

Mr. Harper presented certified copies of the convictions and explained that Mr. Stewart had not appeared earlier in respect of the convictions in 1926 and 1927 because the first four had all been reported together to the Registrar, who had written in October, 1928, warning Mr. Stewart that any further conviction would cause him to be summoned before the Council. The actual language used by Mr. Stewart had been circulated to the members, and in the whole course of his experience Mr. Harper had never known such language used by a medical man.

Mr. Stewart addressed the Council on his own behalf, pleading as extenuating circumstances his war service, testimonials to his work and character, an organised movement to prevent him from practising in the valley, and a severe motor accident involving a compound fracture of the skull in 1926. He still suffered from extreme irritability and scotoma as a result of this injury. He related the events leading to the various fines, claiming that he had been wrongly convicted, largely owing to the animus of a certain constable. He did not think he could possibly have used that language. He expressed his great regret, promised that the offence should never be repeated, and said that he had become a total abstainer.

Mr. H. E. Lewis, clerk to the insurance committee for the County of Glamorgan, testified that Mr. Stewart had increased his panel list every year since he had started. He had appeared several times before the Medical Insurance Subcommittee on the question of these convictions. The subcommittee had talked very seriously to him but did not feel justified in suggesting removal of his name from the list. The subcommittee would be very much surprised if the Council took extreme measures with Mr. Stewart.

The President pointed out that some of the convictions antedated the accident.

In answer to questions by the President, Mr. Stewart said that he had only defended one case ; the bench of magistrates had been the same on each occasion. He read a testimonial from a professional colleague.

The President announced that judgment would be postponed until the November session, 1930. Before that date Mr. Stewart should furnish the Registrar with the names and addresses of professional colleagues willing to testify to his good conduct in the interval, and he must clearly understand that in the event of any further conviction of a like nature in the meantime the Council might direct the Registrar forthwith to remove his name from the Register.

The Case of John Caldwell Fergusson, registered as of 10, Upper Northgate-street, Chester ; M.B.E., M.C., L., L.M., 1915, R.C.P. & S. Irel., who had been summoned to appear before the Council on the following charge :—

"That you were on August 6th, 1929, convicted at the City of Hull Police-court of the following misdemeanours—namely, (1) that you on April 29th, 1929, being a person authorised to supply *preparations*, unlawfully did not keep *in accordance with the provisions of Regulation 11 of the* Dangerous Drugs (Consolidation) Regulations, 1928, a registe and enter therein true particulars with respect to every quantity of a certain preparation, to wit, one pound of tincture of opium obtained by you, contrary to the before-mentioned Regulations made under Section 7 of the Dangerous Drugs Act, 1920, and were fined £2 2*s.* or 20 days' imprisonment and £3 3*s.* costs ; and (2) that you on May 7th 1929, being a person authorised to supply preparations, unlawfully did not keep, in accordance with the provisions of Regulation 11 of the Dangerous Drugs (Consolidation) Regulations, 1928, a register and enter therein true particulars with respect to every quantity of a certain preparation, to wit six ounces of liq. morphinæ hyd., obtained by you, contrary to the before-mentioned Regulations made under Section 7 of the Dangerous Drugs Act, 1920, and were fined £2 2*s.* or 20 days' imprisonment and £3 3*s.* costs."

Mr. Fergusson sent a medical certificate stating that he was suffering from paresis of the left side and tuberculosis of the right lung, and was unable to attend.

Mr. Harper read a long letter he had received from Mr. Fergusson. His poor health and lack of money had prevented him from making a good defence, and he had wrongly supposed that the onus of proof was on the prosecution. His functional disability dated from the time when he had been blown up in Flanders and he had had frequent attacks ever since, involving constant periods of rest alternating with light work. He had had an attack on the morning of the case in court, and his solicitor had not known the Act. The conviction had arisen from the failure of the doctor whose practice he was taking to hand over the poisons register. Mr. Harper read a letter from the chief constable of Northallerton, stating that a local doctor had asserted that Dr. Fergusson was a drug-taker and unfit to practise, and relating several incidents in which Dr. Fergusson had been involved. After deliberation in camera the President announced that the Council had not seen fit to erase Dr. Fergusson's name from the Register.

An Erasure for Drunkenness.

The Case of John Joseph Macabe, registered as of 58, Brunswick-street, Chorlton-on-Medlock, Manchester, M.B., B.Ch. 1918, N.U.Irel., who had been summoned to appear before the Council on the following charge :—

"That you were on April 3rd, 1929, convicted at the Manchester City Police-court of the following misdemeanour —viz., of being drunk and incapable, and were fined 10*s.* or 7 days' imprisonment and your bail of 20*s.* forfeited."

Dr. Macabe had twice before appeared on similar charges. He did not attend and was not represented. The Council directed the Registrar to erase his name from the Register.

COMMITTEE BUSINESS.

EXECUTIVE COMMITTEE, NOV. 25TH.

Official notification was read of the reappointment as members of the Council of Sir George Newman (Crown nominee) for five years from Oct. 9th, 1929, Prof. John Beresford Leathes (representative of the University of Sheffield) for three years from Oct. 27th, and Sir John Moore (representative of the Royal College of Physicians of Ireland) for one year from Oct. 18th.

Restorations to the Register under Section 14.—The prescribed conditions having been fulfilled, the following names, removed through the omission to keep the Registrar informed of change of address, were restored to the Medical Register:—

Mrs. Gertrude E. Bartlett, Thomas L. Bonar, Neville E. Challenger, Thos. H. R. Davies, Mrs. Rose C. D'Monte, George G. Dooley, Bernard C. Ewens, Leonard M. Gabriel, William E. Giblin, John F. Haynes, Sidney Hughes, George C. Jeaffreson, Mrs. May E. Law, Vinayak L. Manker, Charles E. H. Paley, John F. Woodyatt.

Curriculum of the Welsh National School of Medicine. Approval was given to the grant of a Charter of Incorporation with the proviso—

> That the curriculum should be so framed as to afford sufficient opportunities for the study, during the last three years of the course, of physics, chemistry, biology, anatomy, and physiology, in their practical applications to medicine, surgery, and midwifery, and that the student's knowledge of these applications should be subject to test in the final examination,

a recommendation to which the Council attach great importance.

Reciprocity.—The Royal College of Surgeons of England called the attention of the General Medical Council to the difficulties in matters relating to reciprocity of medical registration between this country and British Dominions, particularly as affecting medical graduates in certain British Dominions desirous of obtaining the F.R.C.S.

The Italian Ambassador having inquired whether under the Anglo-Italian agreement of 1925 persons possessing Italian qualifications were entitled to practise in the Union of South Africa, and having asked for a complete list of territories between which and Great Britain reciprocity existed, was informed that the only parts of the Dominions with which reciprocity did not exist were the following Provinces of Canada: British Columbia, New Brunswick, Ontario, Quebec, and Saskatchewan—and that at the present time there was limited reciprocity with New Zealand.

"Army Medical Service" as an Address in the Register.—In consequence of the exception taken by a practitioner to the address "Army Medical Service," the Army Medical Department of the War Office were asked if, in their opinion, the time had come when a change should be made in the title, which had been in use for something like 80 years. They replied giving as the correct description different designations for the various ranks, and it was suggested to them that a generic title which would cover all officers in the Service regardless of rank, and preferably regardless of whether they were still serving or not, was highly desirable for the reasons that army rank was not given in the Register, and that it would be difficult for the Council to ascertain with accuracy whether or not officers were still serving. It was suggested that if it was thought desirable "Royal Army Medical Corps" might be substituted for "Army Medical Service," and the department replied that the case might be met by the substitution of the word "Army" for the present term. It was finally decided to retain the present designation as no real case seemed to have been made out for a change, and it was gathered that there was no strong desire on the part of the department that any change should be made.

Home Office Authorisation.—The Home Office had notified the Council on Oct. 14th that authorisation under the Dangerous Drugs Act, 1920, had been withdrawn from John Caldwell Fergusson, Reginald George Karn, and Frederick Stuart. The cases of Frederick George Lewtas, John Symington Stewart, and Sydney Robert Walker had been previously notified.

OTHER COMMITTEES.

Study of Biophysics and Biochemistry.—Sir Humphry Rolleston, chairman of the Education Committee, presented a report on professional instruction in physics and chemistry in their relation to medicine, particularly during the clinical years. In a special report the committee publish the replies received from the various educational authorities which show that the pre-clinical instruction given in biology, chemistry, and physiology appear satisfactory, but many of the bodies have not provided any information about the continuation of teaching in these subjects during the clinical years, while others remark that the amount of instruction incidentally given during the courses in pathology, pharmacology, and clinical medicine must obviously be determined by the demands of the subject and the personal leanings of the teacher. Sir Humphry moved that the report be referred back until all the teaching bodies had supplied adequate answers on this point. The committee recognise the force of the argument that the pre-clinical subjects should be taught by the clinical teachers in application to the clinical subjects, but it is also aware that all clinicians cannot be presumed to be sufficiently au fait with the progress of biochemistry, physiology and chemistry to foresee the application of their most recent advances to medicine. Applied anatomy is the pre-clinical subject most often taught in a special course during the clinical years, but the clinical pathology course covers a good deal of the ground that might be dealt with in a special course of applied physiology or biochemistry.

The *Examination Committee* has been paying attention to the subjects of medical jurisprudence and public health, and Sir Norman Walker, the chairman, presented an interim report on this subject. In most medical schools courses of instruction are given on each of these two branches, and very often a medical officer of health is the professor of public health or there is a link between the professor and the local health department. Generally speaking, the course of instruction in each subject lasts one term, and students are examined in their final examination, or occasionally at the end of the fourth year of study.

The *Pharmacopœia Committee* reported that 2300 copies of the British Pharmacopœia, 1914, were sold in the year ending Nov. 23rd, 1929, bringing the total to 58,183 copies. Subcommittees on pharmacy, pharmacognosy, and pharmaceutical chemistry have been formed and are preparing monographs, 93 of which have already been circulated. Other subcommittees have been formed to deal with the special subjects of ergot and its preparations; drugs of the arseno-benzine group, standards for ampoule glass, and the preparation of sterile solutions. The commission have inquired into several substances which it is proposed to include in the Pharmacopœia, such as tetra-iodo-phenolphthalein sodium, thyroid gland, and tinctures of strophanthus and squill. The commission hope to establish close coöperation with the United States Pharmacopœia Committee so that the two Pharmacopœias may be unified as far as possible. The report includes a copy of correspondence referring to the proposed international agreement on potent drugs.

The *Public Health Committee* has been visiting examinations for the diploma of public health, and has found that, on the whole, the implications of the Council's regulations have been satisfactorily carried out. Those regulations made such a change in the requirements for the diploma work that difficulties and objections might well have been expected but they are, in fact, conspicuous by their absence. The Committee reports the general impression that the standard is well within the powers of candidates who devote themselves whole-heartedly to their course of study. The examination on special subjects such as meat, structure of premises, and fevers are all strictly practical and conducted at appropriate centres. The diploma covers so wide a field that the balance of theoretical and practical is extremely difficult, and the Committee feels that time alone will show what modifications are desirable in the continuous adoption of the curriculum to the ever-increasing specialisation of public health work. The report was presented by the chairman, Sir John Moore, and Dr. Letheby Tidy was appointed a member in place of the late Sir Jenner Verrall. Dr. H. B.

Brackenbury was elected to take Sir Jenner Verrall's place on the Executive Committee.

Election Rules.—Dr. J. W. Bone, seconded by Dr. H. B. Brackenbury, carried a motion that it be referred to the Finance Committee "to consider and report to the Council whether the regulations for the conduct of elections to the Council (Section 8 of the Medical Act, 1886) and the 'Instructions to Voters' issued in connexion therewith might not be simplified and/or improved." Dr. Bone pointed out that there had been a steady increase in the number of voting papers rendered invalid and that this increase had been a subject of comment in the medical press. The regulation which covers the system of voting had been laid down by the Privy Council, but there were certain incompatibilities between the instructions in the leaflet and those on the ballot paper. It was not certain, for instance, whether the paper was to be sent off or received on the appointed day. Other regulations appeared to be trivial; for example, a paper was rendered invalid if it were folded in the wrong direction. Mr. H. L. Eason quoted the figures of the electorate and the spoiled ballot papers for several past years and showed that there was no real increase in the number of papers rendered invalid. He pointed out that the majority of faults for which papers had been rejected at the last election were faults of gross carelessness and not of trivialities. A large number of empty envelopes had been received, and many others had not been signed; only eight out of the total had been wrongly folded. Sir Robert Bolam pleaded for simplification of the procedure in order that electors should not be deterred from exercising their vote. The matter was referred to the Committee and the Committee was authorised to invite Dr. Bone to attend their meeting to discuss it.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ORTHOPÆDICS.

AT a meeting of this Section held on Dec. 3rd the chair was taken by the President, Mr. McCRAE AITKIN, and Mr. W. H. OGILVIE opened a discussion on

MINOR INJURIES ABOUT THE ELBOW-JOINT.

He classified the minor injuries as partial fractures, partial dislocations, tears of the capsule, traumatic arthritis, and injuries to muscles. He discussed the anatomy of the joint, and demonstrated its division into a posterior trochlear and an anterior condylar portion, resembling those of the lower end of the femur; and pointed out the crescentic facet on the olecranon surface of the ulna, which met the outer lip of the trochlea in full extension; and the triangular groove between the outer part of the transverse groove dividing the greater and lesser sigmoid cavities. The strength of the capsule lay, he said, in the lateral ligaments. The synovial cavity in both radio-ulnar joints was sacciform, allowing for vertical as well as rotary movement. Intracapsular synovial pads were highly developed in the elbow and intra-articular synovial fringes were abundant.

The elbow was designed for use primarily in positions between 110° and 170° of extension and between half and three-quarters pronation. Only within this range was the olecranon portion of the greater sigmoid cavity fully engaged by the trochlear surface of the humerus. In flexion beyond 110° it rode in a groove which was shallow on the outer side, so that part of its bearing surface was exposed. The real humero-ulnar articulation was between the anterior parts of the trochlea and the coronoid articular surface of the olecranon. The olecranon part of the ulna combined the function of a muscular process like the great trochanter and a steadying guiding mechanism like that of the malleoli, the latter function only being called into play in the later degrees of extension. No real disability followed excision of the head of the radius; the ulna formed a platform on which the radius, bearing the hand, was free to rotate. The carrying angle was one of 10–15° and was present in the fœtus and at all ages; it diminished as the arm was flexed and was due to the varying depth of the inner lip of the trochlea. The only acceptable explanation of the carrying angle was the constant use of the half-pronation position. In the position of use—half pronation and nearly complete extension—the purpose of the carrying angle became apparent: to allow the radius to lie in a continuation of the long axis of the humerus. The position of rest—slight flexion and rather more than half pronation—was maintained by the brachialis anticus and from this position the elbow moved for its various functions.

Two distinct sets of uses would be distinguished: those concerning the outer world and those concerning the individual. The exteroceptive range of the elbow embraced the positions from about 90° to 170° of extension and from half to full pronation and involved such movements as attack, cutting food, climbing, and handling tools, and within this range stresses were likely to fall on the elbow-joint. The articular surfaces were fully engaged and the joint was stable. The proprioceptive range included all those movements concerned with the person; from a right angle to full flexion and from half to full pronation; the joint surfaces in this range were poorly adapted and the joint depended on ligaments, but was not exposed to great stress. Full supination was rarely used in extension or full pronation in flexion. Full extension did not occur in natural use. True hyperextension was rare. The apparent hyperextension in some women was due to the demonstration by extreme supination of an exaggerated carrying angle. Upward movement of the radius was checked by the interosseous membrane and downward movement by the oblique cord. The up and down movements of the radius invited comparison with the knee.

Fractures and Dislocations.

Most injuries of the elbow were due to indirect violence. The trochlea and still more the capitellum were carried well forward and apt to be fractured forwards into the joint. Full extension, however, was rare and could not be maintained in the face of force. Falls on the outstretched hand tended to flex the elbow and not to hyperextend it. In the ordinary fall on the outstretched hand the lines of force passed out of the limb posteriorly at an angle and caused supracondylar fracture or backward dislocation. The involvement of the radius depended on the degree to which force applied to it was passed on to the ulna. In a fully pronated and radially adducted position the interosseous ligament was somewhat relaxed and the radius was forced against the capitellum; the blow would therefore tend to fracture the radial head. In partial supination and ulnar adduction a dislocation at the elbow-joint or a fracture of the humerus would be more likely to occur. If the arm was partially flexed the blow would flex it further and the main force be taken on the olecranon; then the trochlea was driven like a cold chisel into the sigmoid fossa and fractured the olecranon transversely. Direct violence usually affected the ulna, but might break any bone.

Supracondylar fracture without displacement was very common in childhood and might be missed in a poor radiogram. Bruises and sprains caused very little limitation of movement in a child and only a little swelling. Treatment involved a few days of immobilisation with active movements from the start. If there was no periosteal stripping there was no risk of bone formation in early active movements. *Isolated fractures of the internal epicondyle* were due to muscular violence and were seen in adults. The joint was not involved and the loose fragment was pulled down by the flexors. Correct position and bony union were seldom secured but the disability was slight. *Fractures of the internal condyle* were oblique, entered the joint, were common in children, and were usually due to falls on the outstretched hand. The broken fragment rode up and the displacement tended to recur when traction was released. *Fractures of the trochlea* alone were very rare. The *external epicondyle* was so small that only cracks or detachment of flakes could be included as isolated fractures. *Fractures of the external condyle* were much commoner and due to force from the ground transmitted through the radius. Cubitus valgus and ulnar palsy were common sequelæ of inadequately treated cases. *Isolated fractures of the capitellum* were rare, and as they were intra-articular there was no deformity, and the diagnosis rested on excessive limitation of function and swelling of the joint. The causative force was more probably direct. In general, direct fixation inside the capsule was undesirable. If the parts could not be fixed by posture or extra-articular screws, traction in flexion by a pin through the olecranon should be tried. *Partial fractures of the olecranon* might be detachment of flakes or fissured fractures without displacement. *Fractures of the coronoid process* were occasionally caused by muscular violence, but much more often by posterior dislocation. *Fractures of the radial head* might be due to falls on the elbow, but were more commonly due to falls on the outstretched hand. They were divided into three types: the first with loose fragments, demanding immediate operation; the second with gross deformity, usually requiring excision of the head; and the third a fissured fracture without much displacement. In the commonest type, however, the fragments retained their normal position. These fractures should be treated as sprains and active rotation started from the beginning. This often restored a full range of movement, whereas excision never gave more than 70 per cent. *Fractures of the neck of the radius* were usually due to indirect violence, and if correct alignment could not be obtained the radial head should be removed. *Fractures of the tubercle* were rare and the result of muscular efforts.

Forward dislocation of the head of the radius was usually associated with fracture of the shaft, but if isolated was usually the result of the radius striking a rounded object on the ground. *Partial subluxations* were not uncommon, but were hard to demonstrate without a stereoscopic radiogram. *Sprain of ligaments* was a clinical diagnosis and not a clearly defined injury; probably muscles were always involved as well. *Tears of muscles* were due to sudden unguarded movement, and could only be distinguished from partial fractures by the X ray appearance and the absence of crepitus. *Spurs of bone* were apt to appear in the muscles of this region in advanced years and the snapping of one of these might cause acute localised pain. *Traumatic myositis* might follow the prolonged and unaccustomed use of any muscle; the whole muscle was tender and showed soft crepitus.

Tennis Elbow.

Tennis elbow eluded classification. It occurred in patients who practised those sports and trades where the arm was suddenly jerked into full extension, while the hand grasped a large object: tennis players, fly-fishers, golfers, sabre fencers, and workers with hammers. The onset was rarely sudden; a gradual ache appeared in the outer side of the elbow, most marked in certain movements, and ceasing when the game ceased. A definite localised tender spot was found in the region of the external epicondyle and clenching the hand was painful, but passive movement was painless. The main theories of its pathology were: (1) tearing of muscles; (2) periostitis; (3) tearing of capsule, involving the external, lateral, or orbicular ligaments; (4) arthritis of radio-humeral joint; and (5) Osgood's bursitis. This bursa lay immediately distal to the external epicondyle, deep to the common origin of the extensor group. Mr. Ogilvie had been unable to find this bursa or to obtain any success by Osgood's operation. All bursæ were abnormal, for they were not present at birth, and might be developed anywhere in response to excessive movement or pressure. Mr. Ogilvie believed that the commonest cause of tennis elbow was tearing of extensor muscle-fibres at their origin from bone, with periostitis sometimes. The radial extensors came into powerful action in gripping movements in tennis. In the first stage the effusion of fluid, local hyperæmia, and round-celled infiltration caused pain and tenderness and were treated by firm pressure, massage, and rest. The second stage of early repair caused pain on certain movements only, aching, and a localised tender spot. Firm pressure by a pad smeared with iodex and strapping at 135°, and active movements, constituted the best treatment. In the third stage there might be adhesions calling for a manipulation such as Mills's. Patients usually came in the second or third stages, and the treatment suitable for one stage was quite unsuitable for the other. Focal sepsis must be sought, as few traumata ran a sterile course. Focal subinfection prolonged the second stage and made adhesions more likely.

There were other types of tennis elbow, however, and symptoms which could not be referred to tearing of the extensor carpi radialis longior. Sometimes there was a true inhibition of movement, causing the patient to drop things. This resembled the sudden giving-way of the knee, and was probably due to a similar internal derangement: a nipping of synovial fringes, especially those thickened by arthritis. Mild traumatic arthritis could be produced by overuse alone—e.g., the return to a strenuous game after a season's rest. Treatment was removal of the causative fringe.

Mr. JENNER VERRALL said that internal derangement as a cause of tennis elbow had long appealed to him, and he agreed with Mr. Ogilvie's remarks about Osgood's bursa. He regarded tennis elbow as possibly a muscular rupture in some cases but more often as a combination of circulating toxins and local trauma. In seeking Osgood's bursa one often found dense fascia between the common extensor origin and the head of the radius, and the opening-up of this explained the good effect of seeking Osgood's bursa as well as of Mills's manipulation, which undoubtedly cured about a third of the cases. Strains on the inner side of the elbow were strictly comparable with those on the outer side, and were nearly all due to tension on the flexor carpi ulnaris. Carried still further, this caused displacement of the ulnar nerve which often could only be cured by shifting the nerve. The forward-dislocated head of the radius did not limit flexion but nearly always caused chronic musculo-spiral neuritis, and it was most important, especially in children, to get the head back into place as soon as possible. After a month or two it might become quite irreplaceable. The construction of a new orbicular ligament with fascia lata was most satisfactory. Early operation was the only possible treatment for fracture of the head of the radius. Excision of the head in a movable elbow left a very weakened elbow, but early excision of small fragments was satisfactory. Fracture of the capitellum was not rare, and operation was the only possible treatment. Fractures of the internal epicondyle were not operated on often enough and were apt to limit movement.

Mr. WATSON JONES showed slides illustrating 5000 cases of elbow injury and pointed out that elbow injuries were most common and most significant in the second decade; in 94 cases of traumatic arthritis perfect cure had been achieved in 92. The problem was not how to cure but how to cure quickly. It was curious that one method or another was often continued as a routine without accurate weekly records of the range of movement. It did not matter what treatment was used so long as progress was checked by measurement. Massage did no good; aided active movements tended to arrest recovery, passive movements were harmful, and manipulation under anæsthesia was disastrous. We were apt to be too anxious about rest; results would improve by steering a course between rest and movement. The patient was the best judge of the amount of movement needed. Fractures of the head of the radius had a grave prognosis. The results might be improved by more radical treatment; the disability was less after excision of the head than after more conservative measures. The limitation of movement was limitation of extension, not of supination and pronation. In fracture of the neck with angulation the head should not be removed but slung in position with an artificial ligament. Fractures of the internal epicondyle could also be produced by direct injury. Ulnar palsies only resulted from indirect injury. The capsule, if pulled in with the epiphysis, dragged on the ulnar nerve and so caused palsy. Treatment was to free the nerve and, if necessary, transfer it to the front of the joint.

Mr. **Whitchurch Howell** said that tennis elbow was the result of bad tennis, and rarely occurred in the professional player. He reported a case of myositis ossificans in the brachialis anticus in a man who fell from his horse and was dragged by the reins, and another of a tramwayman who had had no injury save the constant jerking he sustained in climbing the tram; he had developed two loose bodies in front of the joint.

Mr. **R. C. Elmslie** recorded two cases of tennis elbow; one in his own arm. Most cases came on very gradually indeed and the toxic factor played a large part. The sufferer was the player who went on playing hard tennis at an age when many people gave it up. There were many causes other than tennis; his own might be ascribed to wrenching club-feet. Very characteristic signs were the exact situation of the tender spot over the radio-humeral joint and the pain caused by passive forced flexion of the wrist and pronation and—in more severe conditions—forced extension of the forearm. The combination of the three caused most pain. Supination of the forearm with extended wrist was also very painful. He excluded cases with arthritis from ordinary tennis elbow. His own "elbow" had been cured by removal of a molar tooth with an apical abscess. He cordially agreed that a child whose elbow had been injured would find for itself the movements that were safe and would cure itself better than any masseur could. The masseur would pretend to do a lot and really do very little.

Mr. **W. H. Trethowan** declared that nothing showed a more constant clinical picture than tennis elbow and that the pathology was equally constant. He himself had a tennis elbow due to prawning, which involved lifting weight in extension of the forearm and wrist. Osgood's bursa was nothing more than the extension of the synovial membrane of the radio-humeral joint, and one cause of pain was compression of this pouch by the extensor carpi radialis longior. Tennis elbow was always a traumatic synovitis of the radio-humeral joint. He did not believe sepsis was ever concerned. The results of treatment depended upon the stage at which each form of treatment was applied. Protracted cases were the cases which would not rest.

Mr. **Rocyn Jones** said the pathology of tennis elbow was little known. The lesion was produced by a combination of supination and extension. Mills's manipulation was very valuable in selected cases where there was a pronated arm with flexed wrist and fingers. The treatment was rest, heat, and massage, and, if these failed, operation. Fissured fracture of the head of the radius was difficult to diagnose, except by X rays; there might be some tenderness and elastic swelling; little treatment was required.

Mr. **Philip Figdor** emphasised the importance of active movements.

The **President** said that there was a very similar pain associated with the muscles arising from the internal condyle. Some cases were relieved by a pad and strap and others by manipulation.

Mr. **Ogilvie**, replying, emphasised again the importance of the exteroceptive range. Ankylosis should be in the exteroceptive position; the classical position was only useful to the man who needed two hairbrushes and wanted to get both hands to his mouth at once.

SECTION OF ANÆSTHETICS.

At a meeting of this Section on Dec. 6th, with Dr. **R. E. Apperly**, the President, in the chair, a discussion on

Anæsthesia in Rectal Surgery

was opened by Dr. **J. K. Hasler**. From the anæsthetist's point of view, he said, the surgery of the rectum was particularly satisfactory. In giving a general anæsthetic his ministrations were well out of the way of the surgeon, and if a regional or local administration was needed this part of the body was well adapted for it. Apart from operation for rectal cancer, much shock was uncommon, and the anæsthetist was seldom worried by a patient being in extremis. Of the two groups of rectal operations—the abdominal and the perineal—the former were mostly for dealing with malignant disease connected with the rectum; half of them were for colostomy, and the rest were abdominal resections or operations for insertion of radium into a high growth in the rectum and the associated glands. The surgeon required good abdominal relaxation so as to avoid unnecessary coils of intestine being constantly forced through the wound, and anæsthesia must be deep enough to allow of exploration of the abdomen if necessary in order to ascertain whether there were secondary deposits in the liver. Colostomy was often the precursor of a second operation, and the patient must be kept fit to undergo this in about a fortnight. A good general anæsthetic satisfied the requirements, but each anæsthetist would have his own preference, and should employ the one which yielded him the best results. A general anæsthetic was commonly given for the preliminary colostomy, and for the subsequent operation a spinal anæsthetic was employed in combination with some form of twilight sleep or a light general anæsthesia; but there seemed to be no reason why general anæsthesia should not be dispensed with altogether. Injection of a spinal anæsthetic between the third and fourth lumbar vertebræ caused anæsthesia well above the umbilicus, and gave good abdominal relaxation. Spinal anæsthesia did not always obviate chest complications, but the patients who developed chest trouble after it would probably have fared worse under general anæsthesia.

Perineal operations formed the second or larger group, and here the field for anæsthetics was more varied. The three most common complaints in this region were hæmorrhoids, fissure, and fistula, and these troubles had generally caused much anxiety for a number of years before operation, so that the patients had a characteristic mental state—that of long-continued suffering in silence. Many started to resist with the onset of unconsciousness, and complete relaxation was delayed, especially if the patient was alcoholic. They had to be deeply under the anæsthetic before the operation was begun, otherwise contraction of the leg muscles made it difficult to place them in the lithotomy position, especially when the sphincter was forcibly dilated. The general anæsthetic must at first be given liberally, but this rule did not apply to pure chloroform, whose use for operations involving the anus and the rectal sphincters had been widely condemned. If chloroform anæsthesia was not deep enough when the anus was dilated there was a risk of cardiac inhibition or reflex inhibition of respiration. Yeomans, of New York, considered that chloroform had no place in rectal surgery.

The forms of local anæsthetics used for perineal operations could be classified in three groups: (1) local infiltration of the operation area; (2) extradural anæsthesia brought about by caudal block and sacral block; and (3) intradural or various forms of spinal anæsthesia. In America the caudal block was often combined with trans-sacral block. At the Mayo Clinic intense anæsthesia was produced 10 to 15 minutes after the completion of the injection, and it was expected to last two hours. J. S. Lundy, of that clinic, reported 99 per cent. of successful cases in the smaller rectal operations with this method, and 75 to 85 per cent. in cases of carcinoma of the rectum. Dr. Hasler did not himself expect spinal anæsthesia to last longer than an hour; if an operation was likely to be prolonged, the spinal could be combined with a caudal block; this extra injection took but little time and certainly prolonged the anæsthesia. Recent papers by Pitkin and Kelly suggested that spinocain would be a useful anæsthetic for purely perineal anæsthesia. By tilting the body of the patient either up or down, according to whether the heavy or the light solution had been used, the anæsthetic effect could be limited to the pelvic region. But examination of the literature suggested the drawback that there was risk in altering the patient's position relative to the horizontal plane for at least two hours after the operation, though this risk could perhaps be reduced by using less spinocain. It was not always desirable to produce full relaxation of the sphincters in cases of fistula; it was usually necessary for the surgeon to be able to feel the sphincters while operating. Local anæsthetics, especially spinal ones, relaxed the sphincters too much.

Discussion.

Mr. E. T. C. MILLIGAN said that for many years it was thought that the value of an anæsthetic was enhanced if it relaxed the sphincter ani; and if it did not, the surgeon proceeded to stretch the sphincter forcibly so as to expose the piles. Now, however, the piles were withdrawn from the anus and exposed with dissecting forceps, which made such relaxation needless. But for extensive fistulæ in which the internal opening in relation to the sphincter had not been determined beforehand it was important to feel the tightly gripping sphincters, so that an anæsthetic which relaxed the sphincters was bad. This remark did not apply to simple fistulæ in which the relations of opening to track had been determined beforehand. He thought that both anæsthetist and surgeon should be familiar with all the possible anæsthetics for a given operation, so that a wise choice could be made. Operations for fissure, fistula, and piles were now perfect, and in choosing the anæsthetic the ideal was to banish apprehension before, pain and apprehension during, and pain after the operation. Though caudal block was ideal if it was reliable, he thought that in practice it was uncertain. Local anæsthesia was one of the best forms of anæsthesia for hæmorrhoid operations, but many patients were apprehensive, interpreting every movement as something that would produce pain, and for such rapid and simple operations gas-and-oxygen anæsthesia with preliminary sedative medication seemed the best means of blanking out consciousness. Low spinal or spinal anæsthesia limited to sacral nerves had advantages which made it valuable for operations on the perineum. It was controllable, and had none of the disadvantages of the higher spinal anæsthesia. Most of the bad results following spinal anæsthesia were due to improper selection of cases, and some were ascribable to faulty technique. Post-operative pain bore no relation to the method of anæsthesia.

Dr. A. L. FLEMMING asked whether it was considered that stovaine fixed more certainly and quickly than novocain. He would have thought that the administration of the anæsthetic with the patient in the sitting posture was dangerous. Dr. Hasler seemed to use only a small quantity of the drug. Pitkin apparently did not rely on the inclination or tilt of the patient; if he wanted a high anæsthesia he used a larger quantity of the solution.

Dr. W. HOWARD JONES said he did not know why stovaine was used so much in preference to novocain, which was much less toxic and irritating. The 10 per cent. solution of novocain had a specific gravity of 1·028, and the specific gravity of cerebro-spinal fluid was between 1·004 and 1·008. When the solution was injected into the cerebro-spinal fluid there was, opposite the point of the needle, an equal quantity of cerebro-spinal fluid, and so the specific gravity was reduced, the heavy solution becoming a lighter one. For a complete splanchnic block, 15 drachms of the 10 per cent. solution was injected between the second and third lumbar vertebræ, and the patient was then placed in the Trendelenburg position. The fluid would come to a halt at about the third dorsal segment. On going higher up there was a progressive decrease in the time the anæsthetic lasted, since the duration depended on the degree of concentration of the solution. With the new anæsthetic, percain, it was stated that spinal anæsthesia would last up to four hours, and even a solution of one-twentieth per cent. was effective. He believed it would be very valuable for rectal operations. The first case he had seen at hospital that day was a man of the navvy type who had been admitted as an "emergency" on account of perforated gastric ulcer, and was in intense pain. Dr. Jones had injected a one-twentieth solution of percain, flooding the subarachnoid space as far as the third dorsal vertebra. The pain disappeared immediately, and in ten minutes the abdomen was opened, the ulcer closed, and the abdomen was swabbed out without discomfort. For producing a complete splanchnic block 15 c.cm. were injected without withdrawing cerebro-spinal fluid and the solution would travel as high as the third or second dorsal vertebra. If cerebro-spinal fluid was withdrawn, the subsequent injection would travel higher.

Dr. C. F. HADFIELD expressed his surprise that stovaine could be caused to drop down by change of posture in the way Dr. Hasler had described. His own practice was to place the patient in the Trendelenburg position as soon as the injection had been made. He thought 45 minutes' operating time was all that could be reasonably expected of stovaine in the light form. Formerly he had used 1·0 c.cm. of a 10 per cent. solution, but now he used 0·6 c.cm., and he had noticed no reduction in the anæsthetic effect.

Dr. EVANS submitted that for hæmorrhoids and fistula nothing more than a fairly light anæsthesia was required—i.e., enough to keep the patient quiet and prevent him kicking. Given a good gas-and-oxygen anæsthesia the surgeon could do all that was required in comfort.

The PRESIDENT spoke of abdomino-perineal operations for carcinoma of the rectum, for which he sometimes had to give the anæsthetic—namely, spinal anæsthesia. At the end of the abdominal part of the operation, when putting the patient in the lithotomy position for the perineal part of it, the blood pressure, which previously had been satisfactory, fell considerably and was a cause of anxiety. Recently a surgical colleague at Middlesex Hospital had adopted the plan of doing the perineal part first—i.e., when the spinal anæsthesia was at its best—and concluding with the abdominal stage. The result had been extraordinarily good, and since doing this that surgeon had not lost a case.

Dr. HASLER briefly replied. He said that "light" and "heavy" solutions were relative terms; one contained glucose, the other did not. Both were heavier than cerebro-spinal fluid. With regard to depth of anæsthesia for these operations, he liked to have the patient well under, at the commencement especially, partly because of the general mental and physical state of the patient, partly because of the area of operation concerned. A patient who had had a spinal injection and had low blood pressure should be moved as little as possible for the hour or two following the incision.

SECTION OF OTOLOGY.

AT a meeting held on Dec. 6th the chair was taken by Mr. W. M. MOLLISON, the President, and a paper on

Radiological Diagnosis of Mastoid Disease

was read by Dr. ELSIE MANN. She described the technique adopted in examining the mastoid, and said she now used two lateral views as a routine; the prone position, although it had the advantage of showing the two mastoids on one plate, had not proved sufficiently useful to be made a standard practice. The exposure should be as short as possible when the patient was a child, and it was better to gain the child's confidence than to frighten him by using a clamp. A successful plate from a child under three was obtained more by luck than good management, and occasionally an older child would prove refractory to all persuasion, and would not keep still. Interpretation was not always easy. The mastoids were usually symmetrical but might be cellular on one side and acellular on the other. When they were cellular on both sides the cells were usually symmetrical, which was a useful thing to remember when trying to decide whether a space were an enlarged cell or an area of absorption. Superficial œdema, eczema of the meatus, and furunculosis might all cause blurring of bony detail, but in the absence of these conditions the radiologist could diagnose mastoiditis and give help which, though not infallible, was very useful.

Dr. GRAHAM HODGSON showed slides illustrating the

Diagnostic Value of X Rays of the Temporal Bone.

In one-third of the cases of otosclerosis, he said, X rays would reveal a loss of definition of the basal turn of the cochlea. In another third nothing abnormal could be seen, and in the remaining third there was some lack of definition which the radiologist could not distinguish with certainty from a normal variation. In some advanced cases the changes—which might be described as the difference between a raw grain of rice and the same grain boiled—could also be detected in the capsule of the posterior labyrinth. The extent of the changes did not seem to have much bearing on the symptoms, which perhaps depended more on the distribution than on the extent of the changes. Radiology could be of use in otosclerosis, however, in following the result of treatment and selecting the cases most likely to yield to it. In tumours and fractures the X ray was of definite value, as Dr. Hodgson's slides illustrated, and might detect a fistula in the external canal. Showing slides of mastoids, Dr. Hodgson suggested that a child might be kept momentarily quiet if the radiologist made more noise than it was making itself.

Mr. T. B. LAYTON spoke on the

Value of Radiography in Symptomless Mastoiditis.

He said there was no symptom of inflammation of diploetic tissue of the mastoid bone. All symptoms were evidence either of extension or of absorption of toxins or organisms. Radiology would detect the cases in which there were no symptoms. Any case of otitis media might actually be a mastoiditis, and if it did not quickly get well might be maintained by infection from the mastoid end quite as often as from the nasopharyngeal end. If it did not recover in three or four weeks the mastoid should be considered, and if there was any doubt the mastoid should be dealt with before the nasopharynx, or the case might become incurable by small operation. Caries was followed by sclerosis; radiography should in the future reveal the stage at which sclerosis began, probably two or three months after the onset of otitis media. Early operation gave perfect results without radical operation; after the onset of sclerosis there was less chance of getting the patient quite well. Clearing up the nasopharynx had given most unsatisfactory results in very many cases of running ears. Radiography would segregate the cases of symptomless mastoiditis, and show whether in otitis media the mastoid became inflamed and whether or not it would get well with the otitis.

Mr. T. H. JUST read a paper on the

Diagnosis of Acoustic Tumours.

Rare as these were, he said, every otologist must see them, because some patients complained at first of deafness, tinnitus, and giddiness. From the welter of sometimes contradictory findings he selected as outstanding symptoms: deafness, headache, falling or lurching, failing vision, giddiness, sensory disturbances—usually of the fifth nerve—vomiting, diplopia, paresis, and tinnitus. Cases of endothelioma and cholesteatoma of the meninges showed practically the same symptoms, due to pressure in the posterior fossa. The signs were connected with (1) the eye; (2) the cranial nerves; (3) the cerebellum; and (4) the eighth nerve—i.e., (1) disturbance of vision up to complete blindness; papillœdema; contraction of the visual fields, particularly to colour; spontaneous nystagmus, and diminished or absent corneal reflex; the nystagmus had been present in all of his 33 cases; (2) diminution in sensation or power in the area of the fifth nerve; (3) falling or unsteadiness, and weakness or loss of power in the limbs; (4) middle-ear deafness and loss of function in the vestibular nerve. The simplest test for the cochlear nerve was by means of a heavy and middle fork and a noise box. To be certain of a small diminution of bone conduction was not always a scientific possibility. Mr. Just had ceased to use the rotation test, as all patients showed spontaneous nystagmus and many were spontaneously giddy. The galvanic test was rather uncertain and he preferred the cold caloric test, which produced marked giddiness, errors in pass pointing, and marked and wide nystagmus if the vestibular nerve were working at all. Only the bad ear was syringed.

Dr. W. T. GARDINER read a paper on the same subject, dealing with Edinburgh cases. His findings coincided with those of Mr. Just. Deafness was usually the first symptom. Giddiness, absence of spontaneous pointing error, and spontaneous nystagmus had been the next most common, and the nystagmus was the most useful diagnostic symptom. The cold caloric test was valuable, and had been positive in all the ten cases who had permitted it. Mr. Gardiner thought, however, that the sound ear should be syringed as well as the other. The diplopia was due to the sixth nerve only. Loss of taste and sense of smell had been recorded in a few cases. The radiogram had given great help in two cases, showing enlargement of the internal meatus. Acoustic tumours should be suspected in cases of absolute deafness and loss of vestibular function associated with spontaneous nystagmus in all directions without Rombergism or spontaneous pointing error.

Cases.

Mr. C. GILL-CAREY showed a case of objective tinnitus in which a crackling sound, not exactly synchronising with the pulse, could be heard a foot away.—Mr. O. POPPER declared that this condition was due to rhythmic contraction of the tensor tympani; he himself could produce it voluntarily.—Sir JAMES DUNDAS-GRANT, Mr. L. GRAHAM BROWN, Mr. W. S. ADAMS, and Mr. GILL-CAREY commented on the case and quoted similar ones.—Dr. D. A. IMRIE showed a case of tumour of the nervus acousticus demonstrated by radiography. The difficulties encountered by the radiologist, he said, were the depth of the petrous portion and the impossibility of producing symmetrical views of two sides when the beam was passed along the internal canals. The tumour had been diagnosed by a stereoscopic transorbital view, as suggested by Conte, of Turin, the beam passing through both orbits. This method gave truly symmetrical views of both petrous bones and should lead to earlier diagnosis of acoustic tumours.—Dr. T. B. JOBSON pointed out that this patient had first been seen in the ophthalmological department, at a stage when it was really too late, and the operation had to be one of great magnitude and difficulty. Diagnosis should rest on deafness, vestibular signs, facial paresis, and radiography; to wait for further symptoms involved great risk.—Mr. G. H. STEELE remarked that the case had been an obvious auditory fibroma before operation, yet at operation the growth had been found so deeply embedded in the cerebellum that the diagnosis had been doubted. Six weeks after the first decompression the cerebellum had extruded the tumour, but operation had failed because two large blood-vessels running across the tumour had been ruptured.

Mr. E. WATSON-WILLIAMS showed skiagrams of the temporal bone. One showed extensive destruction by cholesteatomata, and the second showed infection in the mastoid cells in acute otitis media. He agreed with Mr. Layton that the mastoid was not opened early enough or often enough, but not that it should be treated before the nasopharynx. The pharynx should have been treated before three weeks had elapsed; neither end should be treated to the exclusion of the other. In his experience radiology failed to help, and was vague in just those doubtful cases of mastoiditis where help was most needed. The otologist must rely on his clinical findings.

Mr. W. A. MILL showed a case of osteomyelitis of the temporal bone. The man had had a Schwatze operation performed for acute mastoiditis. A month later he had suffered from swelling in the temporal region, headache, and pain, all of which had persisted. Operation a month later had revealed granulations in the mastoid cavity, malleus, and incus, and diseased bone in the squama with thickened dura.

Sir JAMES DUNDAS-GRANT showed skiagrams from a man who had fallen down and been picked up deaf. There was a suggestion of a fracture in the back of the orbit, possibly the labyrinth had been fractured by transmitted force.

Discussion on Papers and Cases.

Mr. A. R. TWEEDIE said that clinical findings must be regarded as more valuable than radiography in deciding what to do in otitis media. He would not open an antrum while a child had offensive tonsils and adenoids.

Mr. LAYTON, in reply, said that radiology was only one piece of evidence in mastoiditis, and that he found it valuable in cases where there was no other evidence. He did not believe that post-aural drainage was a valuable thing if there were no disease of bone. The only way of finding whether bone was involved or not was by radiography. Removal of tonsils which would not be removed save for a running ear never gave any good result; he would not operate on the nasopharynx while an acute infectious process was going on.

Sir JAMES DUNDAS-GRANT urged the value of the unilateral galvanic test for acoustic tumours, with the cathode on the back of the neck and the anode on the ear, and advocated his cold air apparatus.

Mr. TWEEDIE agreed that rotation was not of much value but still hoped to get something from it quantitatively. The galvanic and caloric tests depended very much on the technique. The first thing to note was whether the leaning or the nystagmus appeared first. In middle-ear cases it was possible to get a hyposensitive peripheral organ by the caloric test and a hypersensitive vestibular nerve by the galvanic test. *The galvanic test result was in direct* proportion to the integrity of the ganglion of the vestibular nerve. If the resistance were adjusted the patient would not suffer from the test.

Mr. S. SCOTT said his experience had differed from that of Mr. Just in that the galvanic tests had proved of great value to him; details of technique were very important.

Mr. BROUGHTON BARNES asked whether any changes had been seen in the middle ear.

Mr. JUST, in reply, said he had had no evidence of middle-ear disease in the affected ear.

SECTION OF PSYCHIATRY.

AT a meeting of this Section held on Dec. 10th, the chair was taken by the President, Sir ROBERT ARMSTRONG-JONES. Members of the Section for the Study of Diseases in Children and of the Child Guidance Society attended this meeting.

Dr. BERNARD HART opened a discussion on

THE DIFFICULT CHILD.

He defined the difficult child as one who presented obstacles to the achievement of that internal and external adaptation which constituted the aim of nurture and education. The point of view taken towards him had changed from an ethical to a physical and then to a psychological one. The difficulty had been ascribed to congenital weakness of moral fibre, diseases or defects in various organs, and lack of nervous stability, but these things never filled the whole picture, and failure of perspective must result from concentrating on them. The modern view was that the trouble was similar to that underlying functional nervous disorders, and that the difficult child was likely to become the neurotic adult. There was a failure in adaptation of the individual as a whole and not a disorder of any one system. The trouble could only be fully understood if psychological conceptions were brought to the aid of physical and chemical conceptions. The symptoms displayed by the difficult child were due to a fault in his reaction as an individual. Delinquency and behaviour anomalies were included as well as nervousness and needed treatment along the same lines.

The Child Guidance Movement was an attempt to cope with the problem along those lines. It employed a team of workers, including a psychiatrist, psychologist, and social worker, for it was essential to know much about the child, his mental and physical make-up, his home- and school-life, and the people he met in both environments. In some cases the external agencies must be modified. Team-work of this kind was always somewhat repugnant to the clinically minded physician, even when the team was welded together by the method of the conference. There was also a fear lest the social worker tail should wag the psychiatric dog, but all who had had experience of the social worker's aid would realise that this risk was well worth taking.

The Point of View of the Pædiatrist.

Dr. HECTOR CAMERON described the difficult child as a problem in management, physical culture, and metabolic instability, subject to a vicious circle of conduct and metabolic disorder. His low fat tolerance had long been recognised; great emotional excitement or physical exertion and states of infection caused exhaustion of the slender glycogen resources of the body, or glycopenia, in which condition metabolism of fat was incompletely carried out and intermediate products appeared. In this state vasomotor pallor, amyotonia, yawning, furring of the tongue, nausea, instability of temperature curve, low muscle tone, fainting, and indefinite aches and pains were the rule. Often vomiting dominated the picture; sometimes it was absent or only occasional. In between attacks the child was full of nervous energy, often squinting or stammering, pale, troublesome, incontinent of urine, a bad sleeper, and restless. The hepatic and muscular glycogen played an important part in determining the sugar content of the blood. Opposition, irritability, apprehension, terror, loss of confidence, and loss of the power to concentrate were characteristic mental states both of the nervous child and of insulin hypoglycæmia. The metabolic disorder often expressed itself in a nervous exacerbation. An excitement, a fright, a great intake of fat or an illness might each produce a deterioration in nervous control, showing itself as a failure of concentration culminating in a confusional state; increased opposition and irritability; night terrors, enuresis, or a bout of vomiting. An attack on the metabolic

SECTION OF OTOLOGY.

AT a meeting held on Dec. 6th the chair was taken by Mr. W. M. MOLLISON, the President, and a paper on

Radiological Diagnosis of Mastoid Disease

was read by Dr. ELSIE MANN. She described the technique adopted in examining the mastoid, and said she now used two lateral views as a routine; the prone position, although it had the advantage of showing the two mastoids on one plate, had not proved sufficiently useful to be made a standard practice. The exposure should be as short as possible when the patient was a child, and it was better to gain the child's confidence than to frighten him by using a clamp. A successful plate from a child under three was obtained more by luck than good management, and occasionally an older child would prove refractory to all persuasion, and would not keep still. Interpretation was not always easy. The mastoids were usually symmetrical but might be cellular on one side and acellular on the other. When they were cellular on both sides the cells were usually symmetrical, which was a useful thing to remember when trying to decide whether a space were an enlarged cell or an area of absorption. Superficial œdema, eczema of the meatus, and furunculosis might all cause blurring of bony detail, but in the absence of these conditions the radiologist could diagnose mastoiditis and give help which, though not infallible, was very useful.

Dr. GRAHAM HODGSON showed slides illustrating the

Diagnostic Value of X Rays of the Temporal Bone.

In one-third of the cases of otosclerosis, he said, X rays would reveal a loss of definition of the basal turn of the cochlea. In another third nothing abnormal could be seen, and in the remaining third there was some lack of definition which the radiologist could not distinguish with certainty from a normal variation. In some advanced cases the changes—which might be described as the difference between a raw grain of rice and the same grain boiled—could also be detected in the capsule of the posterior labyrinth. The extent of the changes did not seem to have much bearing on the symptoms, which perhaps depended more on the distribution than on the extent of the changes. Radiology could be of use in otosclerosis, however, in following the result of treatment and selecting the cases most likely to yield to it. In tumours and fractures the X ray was of definite value, as Dr. Hodgson's slides illustrated, and might detect a fistula in the external canal. Showing slides of mastoids, Dr. Hodgson suggested that a child might be kept momentarily quiet if the radiologist made more noise than it was making itself.

Mr. T. B. LAYTON spoke on the

Value of Radiography in Symptomless Mastoiditis.

He said there was no symptom of inflammation of diploetic tissue of the mastoid bone. All symptoms were evidence either of extension or of absorption of toxins or organisms. Radiology would detect the cases in which there were no symptoms. Any case of otitis media might actually be a mastoiditis, and if it did not quickly get well might be maintained by infection from the mastoid end quite as often as from the nasopharyngeal end. If it did not recover in three or four weeks the mastoid should be considered, and if there was any doubt the mastoid should be dealt with before the nasopharynx, or the case might become incurable by small operation. Caries was followed by sclerosis; radiography should in the future reveal the stage at which sclerosis began, probably two or three months after the onset of otitis media. Early operation gave perfect results without radical operation; after the onset of sclerosis there was less chance of getting the patient quite well. Clearing up the nasopharynx had given most unsatisfactory results in very many cases of running ears. Radiography would segregate the cases of symptomless mastoiditis, and show whether in otitis media the mastoid became inflamed and whether or not it would get well with the otitis.

Mr. T. H. JUST read a paper on the

Diagnosis of Acoustic Tumours.

Rare as these were, he said, every otologist must see them, because some patients complained at first of deafness, tinnitus, and giddiness. From the welter of sometimes contradictory findings he selected as outstanding symptoms: deafness, headache, falling or lurching, failing vision, giddiness, sensory disturbances—usually of the fifth nerve—vomiting, diplopia, paresis, and tinnitus. Cases of endothelioma and cholesteatoma of the meninges showed practically the same symptoms, due to pressure in the posterior fossa. The signs were connected with (1) the eye; (2) the cranial nerves; (3) the cerebellum; and (4) the eighth nerve—i.e., (1) disturbance of vision up to complete blindness; papillœdema; contraction of the visual fields, particularly to colour; spontaneous nystagmus, and diminished or absent corneal reflex; the nystagmus had been present in all of his 33 cases; (2) diminution in sensation or power in the area of the fifth nerve; (3) falling or unsteadiness, and weakness or loss of power in the limbs; (4) middle-ear deafness and loss of function in the vestibular nerve. The simplest test for the cochlear nerve was by means of a heavy and middle fork and a noise box. To be certain of a small diminution of bone conduction was not always a scientific possibility. Mr. Just had ceased to use the rotation test, as all patients showed spontaneous nystagmus and many were spontaneously giddy. The galvanic test was rather uncertain and he preferred the cold caloric test, which produced marked giddiness, errors in pass pointing, and marked and wide nystagmus if the vestibular nerve were working at all. Only the bad ear was syringed.

Dr. W. T. GARDINER read a paper on the same subject, dealing with Edinburgh cases. His findings coincided with those of Mr. Just. Deafness was usually the first symptom. Giddiness, absence of spontaneous pointing error, and spontaneous nystagmus had been the next most common, and the nystagmus was the most useful diagnostic symptom. The cold caloric test was valuable, and had been positive in all the ten cases who had permitted it. Mr. Gardiner thought, however, that the sound ear should be syringed as well as the other. The diplopia was due to the sixth nerve only. Loss of taste and sense of smell had been recorded in a few cases. The radiogram had given great help in two cases, showing enlargement of the internal meatus. Acoustic tumours should be suspected in cases of absolute deafness and loss of vestibular function associated with spontaneous nystagmus in all directions without Rombergism or spontaneous pointing error.

Cases.

Mr. C. GILL-CAREY showed a case of objective tinnitus in which a crackling sound, not exactly synchronising with the pulse, could be heard a foot away.—Mr. O. POPPER declared that this condition was due to rhythmic contraction of the tensor tympani; he himself could produce it voluntarily.—Sir JAMES DUNDAS-GRANT, Mr. L. GRAHAM BROWN, Mr. W. S. ADAMS, and Mr. GILL-CAREY commented on the case and quoted similar ones.—Dr. D. A. IMRIE showed a case of tumour of the nervus acousticus demonstrated by radiography. The difficulties encountered by the radiologist, he said, were the depth of the petrous portion and the impossibility of producing symmetrical views of two sides when the beam was passed along the internal canals. The tumour had been diagnosed by a stereoscopic transorbital view, as suggested by Conte, of Turin, the beam passing through both orbits. This method gave truly symmetrical views of both petrous bones and should lead to earlier diagnosis of acoustic tumours.—Dr. T. B. JOBSON pointed out that this patient had first been seen in the ophthalmological department, at a stage when it was really too late, and the operation had to lative effects, and tolerance was very slowly established, if at all. The patients relapsed when the drug was discontinued.

Behaviour disorders might occur in three types of dyspituitarism: (1) patients with increased activity of the anterior lobe, and a tendency to gigantism; (2) those with diminished activity of the posterior lobe and the dystrophia adiposo-genitalis syndrome; (3) mixed types. These disturbances were congenital, but formed a suggestive link between the mental and physical aspects of emotion.

Discussion.

Dr. D. W. WINNICOTT said that the scientific approach to the difficult child must come from a study of the child itself, whose unconscious had very great power over his life, and was not always dealt with sufficiently. All the dreadful things seen in the post-encephalitic child were present in the normal child, but controlled by the ego. Any approach which did not include the unconscious of the child was unscientific.

Miss MARY CHADWICK said there seemed to be excellent equipment for diagnosis but little for treatment. Explaining repressed tendencies would not cure anyone. Questioning a child about its emotions would not give much response. Something must be done to release its emotions and phantasies. One German clinic treated the parents when their neurosis was held to lie at the root of the child's trouble.

Dr. N. H. BURKE analysed 30 case-sheets from the Jewish clinic to illustrate methods of treatment. Home had been wrong in 23 cases; the mind in 24; the school in 7; and the bodily health in 14. Home troubles included parental disharmony or neurosis and injudicious handling; or minor difficulties, such as sleeping accommodation. In a few cases tonsils and adenoids had to come out; there were rheumatisms and debilities, a few heart cases, and a case of tuberculous joints. There had been mental dullness in a few cases; two had been defective, and one excessively intelligent. All had had various degrees of anxiety, fear and neurosis. In two cases nothing could be done with the parents, but partial adjustment had been obtained in 24 and good results in 4. Some cases needed a residential or defective school, and removal from impossible homes; others needed holidays from home—partly for diagnosis, and partly to give the mother a rest; some ought to go to better schools; others were benefited by adjustment of sleeping arrangements, admission to scout or girl guide troops, or psychotherapy. The cinema had only once appeared to have any influence.

Dr. J. D. REES said very few people in this country were doing serious analyses of children, and those who had done it in Vienna were giving it up. Doctors doing child guidance must have the analytical point of view or "environmental treatment" would be "woolly."

Dr. MARGARET LOWENFELD said that removal to a more favourable environment might improve the child, but on return he would react to the same difficulty in the same way. The child who could not deal with a difficult parent would fail later in life to deal with a difficult employer. The only method of treatment was to provide a system of play by which children could build their phantasies and slowly come to understand the reasons for their own behaviour. The child would build within itself a world which expressed its need. The emotional difficulties of childhood were associated with biochemical and physical disturbances, particularly of posture. The release given by the phantasy method was correlated with a change in the biochemical and physical picture. The problem could be approached by either path: physical or emotional.

Dr. HART, in reply, emphasised that we could not afford to neglect or be intolerant of any one of the facets of the problem.

Reviews and Notices of Books.

PSYCHOLOGY.

An Introduction to Individual Psychology. By ALICE RAVEN. Cambridge: W. Heffer and Sons, Ltd. 1929. Pp. 145. 3*s.* 6*d.*

THE title of this book, though more or less accurate in describing its thesis, is somewhat misleading in these days, when the term individual psychology has become synonymous with particular views expressed by Dr. Alfred Adler. But that is scarcely the business of the general reader, who can let the adherents themselves defend the pedestal of the idol. The book is written in a clear style, and is illustrated by a pleasant cultural breadth, but its eclecticism is a little dangerous. For example, while endorsing the very partially dynamic psychology of W. McDougall as regards the instincts and their related emotions, the author accepts fully the foundation principles of Freud's psychopathology, the power psychology of Adler, and the type psychology of Jung. Treating each system superficially, and gleaning what she feels to be most useful, she constructs a fairly coherent system of psychology. But careful analysis of her origins will bring out the glaring inconsistencies of this eclectic method. However, the very readable analyses of the plays of Æschylus, and of the character of Meleager in Swinburne's Atalanta, makes amends for he offences against established systems and the lack of logical coherence in her philosophy. Those who are familiar with the schools of thought from which it has been evolved will find this little book an interesting study.

PHYSICAL THERAPEUTIC TECHNIC.

By FRANK BUTLER GRANGER, A.B., M.D., Director of Physiotherapy, United States Army. London: W. B. Saunders Company. 1929. Pp. 417. 30*s.*

On Prescribing Physical Treatment. By MATTHEW B. RAY, D.S.O., M.D. Edin., Physician to the St. Marylebone General Dispensary. London: William Heinemann, Ltd. 1929. Pp. 179. 10*s.* 6*d.*

Dr. Granger's book is intended for the general practitioner who wishes to apply physical treatment only occasionally. It is chiefly devoted to electrical methods, and hydrotherapy and massage are passed over somewhat sketchily. The first part of the book is encumbered with elementary theoretical matter which the physician with any aptitude for the use of electricity will not need, but the last 17 chapters describe in close detail the treatment of various pathological conditions and should be helpful. Two useful features are Dr. F. A. Davis's synopsis of physiotherapeutic methods, a tabular description of the chief devices in use to-day, and the chapter on a hospital department of physical therapy, which suggests a basis for the initial foundation of a physical treatment branch, with lists of personnel and apparatus. The work is copiously illustrated, but would have been improved by a more careful selection of the pictures. It suffers from the common fault of containing a large number both of manufacturers' woodcuts, and of photographs of treatment which do not teach anything in particular.

Dr. M. B. Ray in his smaller book places balneotherapy in the foreground. He deals very little with theory, and arranges his material according to method, giving the indications for each kind of treatment as he describes it. This presentation has the defect that the practitioner who wishes to treat a certain condition must turn up several places in the book and collate the information. In many cases the descriptions have been curtailed to avoid a repetition which would have been useful, and the index is unfortunately not complete enough to support this method of arrangement. Nevertheless, this short text-book of medical hydrology and, to a lesser degree, of electrotherapy and other physical methods, is com-

comprehensive and crisp. Dr. Ray writes incisively and wastes no words, and his intelligent paragraphing, frequent side-headings, and individual page headings make the book easy to read.

SKIN DISEASES.

Grundriss der Arzneimittellehre für die Behandlung von Hautkrankheiten. By Dr. K. FÜRST, Frankfurt a/M. Leipzig: Georg Thieme. 1929. Pp. 144. M.6.

THIS small manual, which deals concisely with the external remedies in common use for the treatment of skin diseases, will be much appreciated by the thoughtful and scientific therapeutist. The author, formerly a pupil of the Herxheimer school at Frankfurt, wisely confines himself to a description of only 28 of what may be called the fundamental therapeutic elements that have withstood the test of 50 and more years of dermatological practice. They are arranged in alphabetical order, from arsenic to zinc, and each substance is considered from the aspects of its medical history, its chemical formula and attributes, its pharmacological actions, its therapeutic indications and modes of applying, and finally its toxic effects (if any) and its contra-indications. This methodical arrangement is conscientiously adhered to throughout, and the result is easily comprehended and memorised.

The work will, however, be found most useful as a book of reference. The classical *formulæ* for arsenic pills, lead plaster, and boric ointment, and the antidotes for cases of poisoning from the use of any of them, could not have been collected with more care or more concisely described. The intending purchaser will do well to note that the book contains no reference to any of the complicated modern remedies which Ehrlich and his school have introduced. There is no mention of salvarsan. There is an appendix of the literature of each medicament, and the index deals not only with these but includes also the diseases for which they are indicated. The work therefore serves both a pharmacological and therapeutic purpose.

MODERN METHODS OF TREATMENT.

Second edition. By LOGAN CLENDENING, M.D., Associate Professor of Medicine of the University of Kansas; Attending Physician, Kansas City General Hospital. London: Henry Kimpton. Pp. 815. 45*s.*

THE efforts being made to rescue the practice of therapeutics from the empirical methods of the past and to establish it on firm physiological and pathological principles are bearing fruit, but we are still much in the transition stage. Authors of text-books on therapeutics have to compromise between a pure exposition of principles on the one hand and a bald and dogmatic statement of methods on the other. Dr. Clendening attacks the problem with a decided modern bias which increases the value of his book as an impartial survey of present-day views on treatment, but is rather a disadvantage if an index of therapeutics for rapid reference is desired. A profound respect for the work of the pioneers and an extensive knowledge of more recent research lead him at times to submerge his own personality in a welter of rival opinions and conflicting theories. The passages in which he gives his own opinions are written in a vigorous and entertaining style, and indicate a wide clinical experience and a sound and conservative judgment.

The book, which deals only with medical treatment and omits all branches of surgery and diseases of the skin, is divided into two parts. The first deals with the methods used in therapeutics, and consists of chapters on drugs, sera and vaccines, gland extracts, dietetics, hydrotherapy, psychotherapy, and miscellaneous procedures. In two short chapters on radiotherapy and massage an attempt is made to describe the elements of technique in these very special subjects. In the chapter dealing with drugs the various remedies are arranged in groups according to their action—a method having certain advantages but apt to be confusing for such widely useful substances as the iodides. Twenty-two pages are devoted to digitalis, but the author holds that in practice "the only sensible way to exhibit digitalis is to return to the method of Withering."

The second part of the book takes the form of an index of treatment and the various diseases are again arranged in groups: diseases of metabolism, diseases of the kidney, and so forth. In both parts of the book a fairly extensive bibliography is provided at the end of each chapter, mainly compiled from American publications. A rather serious fault is the lack of cross references in the text between the two parts of the book. Often mention is made in the second part of methods which are recommended in the first. For instance, in the section on dietetics the Minot-Murphy diet is described in detail; but no reference to this is made in the directions for the treatment of pernicious anæmia, though the method is briefly alluded to and a number of recipes are given. In a volume arranged on this principle a complete system of cross references is very necessary, and its omission is not covered by the excellent index.

Dr. Clendening deserves praise for the admirably compact and lucid way in which he summarises modern work; the first part of his work is enriched by well-chosen quotations from original sources.

ELEMENTARY ANATOMY AND PHYSIOLOGY FOR NURSES.

By P. M. LODGE. London: J. and A. Churchill. 1929. Pp. 82. 3*s.* 6*d.*

THIS little book, based on lectures given at Birmingham to probationers, seems to us to be an exceedingly suitable work for the purpose. It is simply and clearly expressed and not burdened with a mass of wearisome (because misunderstood) detail, like so many of the manuals for nurses. It is calculated to give the probationer—and perhaps her senior colleague—a good and useful idea of the main structures and activities of the body. Its general value is not appreciably lessened by a few slips which can easily be corrected in a future issue.

THOSE TEETH OF YOURS.

By J. MENZIES CAMPBELL, L.D.S., D.D.S., F.R.S.E. London: William Heinemann (Medical Books), Ltd. 1929. Pp. 141. 3*s.* 6*d.*

THIS book is described as a popular guide to the teeth. It well fulfils this description and is an excellent example of a book suitable for the layman. Books on medical subjects intended for a lay audience fall into two categories—the brief, elementary manual couched in simple language which is intended for the personal guidance of those who read it, and the more advanced book suitable for teachers or those of more than average technical knowledge. This book is an example of the last-named type. It covers a wide range and the author supplies more than a practical guide to dental hygiene; he has included an interesting note on the historical side of dentistry. In discussing the treatment of dental disease Mr. Campbell goes into such questions as the different ways of filling teeth, anæsthesia, the various forms of dentures, and the advantages of gold and vulcanite. This is done not with the idea of usurping the province of the dentist but in order to give the reader some idea of the scope of his work. A diligent reader of this book might prove a somewhat captious patient if his professional attendant adopted a procedure not in accordance with Mr. Campbell's views, but on the whole a patient not wholly ignorant of the technical side of dentistry is more likely to coöperate intelligently in any treatment. Mr. Campbell has managed to pack much information into a little over 100 pages. Some of it will be new to those many medical men who have had no special experience in dental work, and they will find it highly profitable to familiarise themselves with the mechanical problems at issue and how they are solved.

THE LANCET.

LONDON: SATURDAY, DECEMBER 14, 1929.

SOMNAMBULISM AS A DEFENCE.

THE trial of MAGGIE ALEXANDER at the Hampshire *Assizes at the end of last month* was noteworthy for the unusual defence of somnambulism as an answer to a charge of murder. There was definite evidence that the accused sometimes walked in her sleep; there was also strong evidence that she had been in a state of acute mental distress and despondency. It is interesting to observe the attitude of the criminal law towards these two conditions. Do both of them amount to legal insanity, or were they possibly alternative defences?

Briefly the story told at the trial amounted to this: the accused had been told by her parents to break off her association with a man with whom she had become infatuated; unless she did so, they said, the home would be broken up, she would have to find a permanent situation, and her little boy would have to go into an institution. After she left home to go to her work next morning, the boy was found lying on the bed with gaping wounds in his throat; a blood-stained razor was discovered in the room. Asked by her mother why she had killed the child, the accused said she thought he would be better off. It was understood that four years ago she was jilted by a young man a few days before the date fixed for her wedding. The crux of the case was the mental state of the accused at the moment when she killed (as the defence did not dispute she did) her child; the observations of Mr. Justice CHARLES on this point will be mentioned later. Important evidence was given by Dr. WATSON, senior medical officer of Brixton Prison. He agreed, in answer to defendant's counsel, that it was possible that the killing occurred in a condition of somnambulism without the woman remembering or knowing anything about it. He had not personally met such a case nor read of one; he would not call it impossible but he would say it was improbable. He had had two long interviews with the accused in the prison and had formed the opinion that she was not insane. From her medical history *he thought she was a somnambulist; he believed her* statement that she had no recollection of committing the act, but this might be due to the suppression in the mind of a distasteful act—a very common feature in such cases. In answer to the judge, Dr. WATSON said that a woman walking in her sleep would not have her mind consciously functioning; although in a medical sense she might not be insane, she would not know the nature and quality of the act she was committing nor would she know that the act was wrong. Mr. Justice CHARLES, a judge of strong common sense and considerable experience in criminal law, left the matter to the jury in the following way. If the woman was so distraught that she did not know what she was doing, he failed to see how she could be guilty. If, on the other hand, she killed her child simply because she was miserable, in a fit of spleen or disappointment, or because she thought the boy was going to be taken away from her, then she did it knowing that she was doing it and must not do it, and in that case the jury must find her guilty. If they accepted the suggestion—and it was rather more than a suggestion—that the accused was a somnambulist, that she committed this act in a state of somnambulism and therefore did not know what she was doing, that she did not appreciate the nature and quality of the act, that she did not know she was doing it at all because of this somnambulistic state from which she unquestionably suffered, then their duty would be to find that she was guilty but insane. The judge added that, if they had any honest doubt whether the killing were done deliberately, intently and consciously, or whether it was done under the influence of somnambulism, then the prisoner was entitled to the benefit of it. *The jury, after a brief* absence from court, returned a verdict of guilty but insane.

The case gives rise to two comments. First, the state of somnambulism is not a state of insanity. A sleep-walker is not insane either in a medical or a popular sense. It is not the act *per se* which the judge and jury must consider, but the state of mind which prompts, and manifests itself in, the act. A sleep-walker is not to be punished for an act done in sleep. It is a difficulty of MAGGIE ALEXANDER's case, so far as the available reports of it go, that we do not know whether the jury thought she killed the boy *while she was awake but in a state of mental* instability, or whether she killed him while in her sleep. The second comment arises over the ridiculous formula "guilty but insane," to which the law still clings though the Atkin Committee on Insanity and Crime condemned it six years ago. "Guilty" connotes criminality; insanity negatives the existence of the criminal mind. A finding of insanity is an acquittal. The legal questions of insanity and crime are complicated enough without perpetuating a form of verdict which is illogical and a fallacy. Is there any hope that in the impending reform of the law of lunacy a brief clause can be inserted to remove this *unnecessary element of confusion?*

◆

INFECTION BY FOMITES.

IN the course of a serious discussion a medical officer of health of considerable standing said he had never been able to trace the origin of a single case of scarlet fever. Although this statement obviously needs qualification as regards secondary cases and return cases, and those occurring in milk-spread epidemics, it may be taken to represent the experience generally of people actively engaged in public health work. *What is true of scarlet fever is true of many* of the cases of other infectious diseases—certainly of those met with in this country. We know that missed cases and carriers are often responsible for spreading infection but informed opinion wavers over the importance of fomites—just as uninformed opinion has always wavered over the probable meaning of this peculiar word. At present it is the fashion not to lay much emphasis on the rôle of infected articles, but it must be confessed that the grounds for disregarding it are not abundant. That fomites *can* spread infectious disease has been proved over and over again; that clothing and especially underclothing and bed linen—*articles which come into the* closest possible contact with the skin—are able to maintain viruses in activity, has been demonstrated by numerous observers. In a classical report published in 1886, Dr. H. F. PARSONS quoted the experience of medical officers in various parts of the country where woollen rags and mixed woollen and cotton rags were used in the manufacture of shoddy, rag-flock, and similar substances. In 1880 Mr. Greenwood, the medical officer of health of Ossett, in Yorkshire, had attributed a case of small-pox to infection from rags which the patient was sorting. Dr. Goldie, medical officer for Leeds, had given similar instances; in Gloucestershire the source of small-pox among women at the shoddy mills at Chalford and Brinscombe in the Stroud Valley was thought to be rags. Medical literature yielded many other descriptions of outbreaks of small-pox among rag-sorters at paper mills in different parts of the country, traced to the use of calico rags, evidently derived from underclothing and bed sheets. The mills making the best writing-papers from white rags were especially affected, and it is noteworthy that rags used for this purpose are cut up by hand. Since then there have been so many instances of small-pox being spread by fomites that belief in this method of spread is now general. The recent Hendon outbreak showed that laundry workers are in danger from infected garments, and we have plenty of evidence that the virus of small-pox can survive for considerable periods.

Reading into Parsons's 1886 report the new knowledge that typhus fever is lice-borne we are fully prepared to believe in his fatal case of typhus contracted by a rag-sorter from rags. Murchison had earlier observed that laundry-women are especially liable to contract this disease without direct communication with the sick, and text-book writers had accepted the view that clothes and bedding may become vehicles for the transmission of typhus. We now know that lice infected with virus of typhus can survive only for a limited period without getting food in the form of blood, and in certain other diseases there are factors which limit the danger of infection. Thus when a serious invasion of this country by cholera was feared about 1890, the Local Government Board made regulations requiring the disinfection of imported rags; but according to present opinion any such danger would be minimised by the facts that the cholera vibrio is readily destroyed by drying and is easily crowded out by saprophytic micro-organisms, so that contamination must be recent to be effective. Typhoid fever, on the other hand, may be contracted by handling clothes of patients which were stained with fæces or urine quite a long time ago. Parsons was further able to record four cases of blood poisoning among agricultural labourers due to the handling of infected waste from rags which were spread on the land as manure, and evidence is available on the spread of scabies by rags.

For many years the Government of South Africa have required that all second-hand clothing and rags should be adequately disinfected before admission into the country, and lately the administrative arrangements have been tightened up. In South Africa there is a considerable trade in second-hand clothes; the natives coming into towns and undertaking industrial occupation resort to such European clothing as can be obtained at a price within their means. Doubtless the medical advisers of the Government have been right to ensure disinfection to avoid any spread of small-pox and other diseases in a semi-civilised community where they would be difficult to control, but recently similar regulations have been enacted in a country where the same conditions do not apply—namely, the Irish Free State. When, a week or two ago, a question was asked in the British Parliament concerning the need for disinfecting imported second-hand clothing, the official reply indicated that the precaution was held unnecessary. This answer seems to be based on the considerations that most of the small-pox present in this country is of the mild type and due to the spread of infection from case to case, that recent outbreaks of small-pox imported from abroad have been attributable to definite cases of the disease, and that of late years no instance of small-pox due to imported infected second-hand clothing has been traced nor has this source given cause for suspicion. In these circumstances it is considered inadvisable to burden importers with the trouble and expense of disinfection.

THE CENTRAL BUREAU OF HOSPITAL INFORMATION.

The origin of the Central Bureau of Hospital Information is of historic interest. It will be remembered that in 1914 a Hospital Economy Committee was set up by the War Office as a check on expenditure in the hastily improvised institutions under the control of persons inexperienced in administration. Remarkable differences in the consumption, especially of two articles, tea and soap, were observed in the various institutions visited; similar observations were made with regard to dressings, drugs, and articles of food, and soon it was possible to demolish the argument which assumes that because hospitals deal with patients whose requirements differ greatly, it is impracticable to establish standards of consumption. The Hospital Economy Committee proved up to the hilt that, without reliable relevant figures, an administrator cannot exercise effective control over his institution, but is at the mercy of his subordinates. Eventually all must bow down to returns which show with remorseless accuracy the expenditure of material or money on the performance of some unit operation, whether that be the supplying of bread to 100 persons for one day or of soap for the cleansing of 1000 articles. The close contact established between the Economy Committee and the voluntary hospitals during the war was in danger of dissolution on the declaration of peace and the gradual demobilisation of the military establishments. It was, therefore, fortunate that the Joint Council of the Order of St. John and the British Red Cross Society provided a bridge, and by the establishment of a Hospital Services Department kept available much that had been learnt during the war. This department at once took up the task of surveying the work and finances to the voluntary provincial hospitals, giving statistical information in a report published each year. The preparation of this provincial report naturally established a certain degree of contact between the individual hospital and a central body, and a good deal of information of a useful administrative character was collected. It was not, however, until a junction was effected between the Joint Council and the British Hospitals Association that the bureau of information could be considered to rest upon a firm foundation. This was provided in 1927, and the Central Bureau of Hospital Information now carries out its work on the authority of the hospitals themselves. This is, of course, a most important point, for in order to be successful it is essential that a centre should enjoy the confidence and the goodwill of the units that surround it. In addition to the publication of its annual report, the Bureau undertakes inquiries on the request of individual hospitals. It depends on the importance of the subject whether an inquiry results in a memorandum issued to all hospitals or is confined to a smaller number. The work of the Bureau is growing each month, and there will shortly be attached to it a hospital library where books and plans may be consulted. In short, the Bureau aims at becoming the intelligence department of the whole hospital system of Great Britain. To this end it is anxious to secure the goodwill and help of all foreign and international associations concerned with hospital administration. We trust that the publicity accorded to its efforts in an international contemporary will achieve this result, for the story of the Bureau is fully told in the last issue of the *World's Health* by Mr. R. H. P. Orde, hon. secretary of the British Hospitals Association.

Annotations.

"Ne quid nimis."

AN UNSOLVED PROBLEM.

AT five years of age one-quarter of the children entering school are in need of medical attention according to the Chief Medical Officer of the Board of Education, who devotes several pages of his annual report[1] to what he calls the problem of the nurture and upbringing of the pre-school child. This problem, we are told, remains unsolved in spite of the 2776 infant welfare centres and an army of health visitors. The Maternity and Child Welfare Act of 1918 has done much for the child under one year, but the arrangements are almost wholly undeveloped for those aged 2 to 5, or what is known as the pre-school group. The result of the lack of provision for this group is to burden the school medical service financially and administratively with the physical and mental defects and impairment of an earlier age, to put the clock back for all the benefit won in the infant welfare centres, and to prejudice both the health and the education of the children as a whole. At present in England and Wales there are 2,000,000 children in this group. A large number, some 165,000, are in attendance at elementary schools where special provision of a limited character may or may not be made for them. Twenty-eight nursery schools are in existence accommodating about 1000 children, and there are 98 day nurseries which admit children from one month upwards. Altogether the special provision for these 2,000,000 children is almost negligible. What is needed now, and urgently needed, is the application of some approved method, an application which can only be effective if it is general or even universal. "If," says Sir George Newman, "we give the child up to five at least as good a chance of physical health as the school child obtains, the result will be sure." And he goes on to say: "It is as certain as the law of cause and effect that whenever and wherever we safeguard early childhood—by wise mothering, by good home conditions, by appropriate child nursing, by child welfare centres, by nursery schools—then and there we get improved physical conditions in childhood."

Wise mothering we are doing our best to obtain through maternity and child welfare services which are also responsible for infant welfare centres. Home conditions are being improved slowly but surely by housing and town-planning schemes. Child nursing has been demonstrated by Dame Janet Campbell in her recent report on infantile mortality to be the *next important step in the child welfare campaign*, only the nursery school lags behind waiting for more forceful encouragement from headquarters. Undoubtedly the extension of nursery school provision will do much to solve the problem of the care of the pre-school child. The nursery school is an evolutionary advance on the day nursery, whose original function of "minding" the children of the mother who went out to work has settled into two divisions: the care of the infant from 1 month and the care of older children from 2 onwards. It is now found that although the child under 2 can be adequately cared for in a day nursery, the child of 2 or over requires more than nursing or "minding." It is out of this idea that the nursery school has evolved. Its function is concentrated on the general nurture of the child physically and mentally from the age of 2 upwards, guiding natural instincts into correct habits and associations, encouraging efforts at reasoning, discrimination, and coördination—in fact, helping the child along the path of self-education and of independence by means of careful and skilled guidance at the hands of teachers specially trained for the work.

Such a system of hygienic and educational care for the pre-school child is naturally simpler to devise for an urban than for a rural area as is indicated in the report, but now that educational provision for rural children from 11 upwards is to be centralised in special areas it ought to be possible to organise in villages and small towns what might be called health and education centres to include the infant welfare centre, the nursery, and the primary school for children up to 11 years of age. As far back as 1908 a consultative committee of the Board of Education issued a report in which they arrived at the conclusion that the best place for children whose home conditions were unsatisfactory was the nursery school. Referring to this report Sir George Newman says: "In our own day we have at least comprehended the problem." Alas, it is a far cry now to 1908, and very many, indeed millions of 5-year-old children, healthy and diseased, have passed the portals of the elementary schools since then. The problem remains unsolved. It is still, where 2,000,000 children are concerned, one of the most important and urgent of public medical problems. We understand that 15 new nursery schools have been sanctioned, which brings the number up to 43. Forty-three schools, each accommodating 100–200 children, is but a drop in the ocean.

A SURVEY OF EPIDEMIC ENCEPHALITIS.

THE Commission organised and financed by Dr. William John Matheson of New York for the study of epidemic encephalitis has issued the first instalment of its report.[1] The Commission has considered the first essential to be a complete survey of the whole subject as it is known to-day. Such a survey of a disease, which though recent in appearance has become world-wide in its spread, is in itself no light undertaking, and it is evident that the Commission has set about its task with breadth of outlook and a characteristic thoroughness. Dr. Josephine B. Neal, in addition to obtaining all the information available from contemporary literature, has made an extended tour of this country and of those parts of Europe in which the earlier outbreaks of the disease were observed, interviewing personally those who have had large experience of the disease. The general summary of ætiology presents in clear and concise language the various stages through which the pathological investigations of different schools have passed during these 10 years. Complete success, it is evident, has not yet been achieved, but it must not be forgotten that during the last few years there has been an increasing difficulty in obtaining material for investigation from acute cases.

The long chapter on epidemiology, with its vast amount of statistical information, will, we think, prove to be the most useful section of the survey. It comes as rather a surprise to find that the total number of cases known to have occurred in England and Wales exceeds those known to have occurred in any other country in the world by a very large margin of 5000. The feeling cannot be repressed that this may be the result of notification rather than of incidence. The résumé of the various methods of treatment tried in different countries at different times reveals the meagre therapeutic importance what has yet been achieved and gives point to intention of the Commission to study for itself treatment of 400 patients over a period of two with adequate controls. The bibliography contains something like 5000 references—more than one paper per day for 10 years—an output which is the measure of the interest which the disease has excited wherever it has appeared. For collecting and codifying this information in such a pleasant and convenient format the English-speaking world owes a debt to the Matheson Commission.

OVARIAN GRAFTS.

THE study of organ transplantation has opened up a wide field of surgical research, but the results so far obtained have been disappointing from a therapeutic point of view. For some considerable time now attempts have been made to transplant the sex glands, especially the ovaries, for there are a number of clinical conditions in which this form of treatment would appear to be indicated. Opinion is more or less unanimous that heterografting, transplantation from one individual to another of a different species, is a failure. G. Schoene, who published a monograph on this question in 1912, concluded that this was to some extent due to too great divergencies in the metabolism of the two species. No real advance has been made in recent years, and it may be concluded that heterotransplantation has not justified its use in human surgery. The therapeutic future of transplantation so far as the ovary is concerned would seem to lie in the homograft—that is, transplantation from one individual to another of the same species. Up to the present, however, experiments in animals have been attended with greater success than those in human beings. I. Kross[1] in 1925 performed transplantation of immature rat ovaries into sexually mature castrated rats, observing the results for periods up to 9½ months. These grafts survived in the castrated animals far longer than in noncastrated controls, and Kross attributed his success to the use of immature ovaries in which the potentialities of growth were high. In the human subject homotransplantation has been carried out in several series of cases, notably those reported by Lesnoi, Magnani, Perezzi, Schultze, and Schreiner,[2] but with varying results. V. Pettinari, in a recent thesis (Paris 1928), reviewed the present position and in addition reported results of a number of grafts on his own cases. In his opinion, only occasional results can be expected from homografts, though he thinks that the method is worthy of a trial in certain cases of infantilism with hypoplasia of the genitalia and other cases of this kind in which ordinary therapeutic measures have failed. He lays great stress on the individuals being of the same blood grouping and in endocrine equilibrium. The operation may apparently be carried out without much surgical risk, but its results are not very encouraging. With regard to auto-transplantation—that is, removal of the ovary to some other part of the body of the same individual—there is almost general agreement as to its field of usefulness in young women of sexual maturity in whom adnexal disease has necessitated bilateral oöphorectomy. The symptoms of the artificial climacteric can thereby be prevented or delayed, and, if the uterus is retained, menstruation generally becomes re-established and continues regularly for a few years. A large number of successfully treated cases have been described by Unterberger, Cramer, Blair Bell, Sippel,[3] and, recently, by C. C. Norris and C. A. Behney.[4] The latter consider that the life of the auto-transplanted ovary is probably not more than two or three years and in this they are in agreement with the majority. In their group of cases most of the grafts, which were made into the rectus muscle, took and the operation was practically without mortality. The grafts occasionally became tender for a day or two each month, but rarely gave rise to serious trouble.

THE TREATMENT OF SYPHILIS.

MANY discussions on the treatment of syphilis have taken place in the United States recently and it is clear that the questions which still exercise the minds of practitioners are (1) what constitutes a complete cure, and (2) what methods are available for detecting latent disease in the absence of definite clinical signs. Unfortunately for the solution of these problems, as W. E. Coutts[1] has recently pointed out our evaluation of remedies is based mainly on the results obtained in experimental rabbit syphilis, on the rapidity of healing of a lesion, and on favourable changes in blood reactions and clinical symptoms, whereas the final test of efficiency of any antisyphilitic agent must be gauged by the ultimate fate of patients—years after the cessation of treatment—as well as upon records furnished by postmortem examination. It is regrettable, in view of this undoubted fact, that the death certificate of a syphilitic person seldom gives any indication of his infection. Dr. Coutts anticipates no dramatic advance in syphilotherapy until the life-cycle of the infecting agent has been elucidated, until problems such as the existence of spirochætes with particular dermotropic or neurotropic affinities have definitely been solved, or until laboratory tests have become even more sensitive and reliable. He may be too pessimistic but it must be admitted that at present no assurance of cure can be given merely on a series of negative serological tests. In fact the exact position of the Wassermann reaction and the various precipitation tests as an indication of cure is still a constant source of argument between the clinician and the laboratory worker. The reliability of the Wassermann test has been keenly criticised, but the original test and its modifications have, nevertheless, withstood attack for 25 years, and the Wassermann reaction remains to-day one of the most valuable laboratory procedures known to medicine. Those of its modifications which have been recommended in the green books published by the Medical Research Council have passed a severe specificity trial organised by the League of Nations in serological laboratories of repute. As between the Wassermann reaction and the newer precipitation tests, Kolmer,[2] who has had an extensive experience of both the clinical and the serological aspects of syphilis, holds that where possible a complement-fixation test as well as a precipitation test should be done; when one test only is feasible, he prefers a complement-fixation test. Believing, as he does, that the strength of a laboratory serological test is proportional to the degree of spirochætal activity, it follows that in his view clinical symptoms depend more on where the activity is occurring than on the amount of activity. According to this theory a few organisms may produce symptoms of syphilis with insufficient reaction for a positive serological test or, on the other hand, a number of organisms large enough to determine a pronounced positive reaction may cause no immediate symptoms. Kolmer urges the clinician not to ignore positive reactions when clinical signs are absent, but rather to suspect negative ones where such signs are present. With regard to negative reactions, Belding[3] expresses the generally accepted opinion that the syphilitic antibody shows no intensification as the result of a provocative injection of an arsenical preparation. From the aspect of treatment it is fortunate that positive serum reactions usually precede clinical signs of relapsing syphilis; hence the value of periodic

tests, for they give a warning that further treatment should be given before any symptoms or signs of tissue destruction, which may be irreparable, have appeared. Hazen[4] and others insist, moreover, that no clinical examination is complete without an observation of the heart and great vessels with the fluorescent screen. There is evidence that involvement of the nervous system occurs early in the disease—a clear indication that the cerebro-spinal fluid should be examined as a routine at the end of any course of treatment and again on the occurrence of the slightest clinical sign. The protean nature of syphilitic lesions indicates that the manifestations probably depend more on the soil on which the infection falls than on variations in virulence or species of the invading spirochæte. Of recent years there has been a tendency to standardise the treatment of syphilis to the neglect of consideration of the individual. So much has been written in medical literature of the merits of this or that particular remedy, of the superiority of arsenic to bismuth and vice versa, that doctors tend to adopt one preparation for routine use, forgetting that one agent may succeed where another fails. The effective treatment of syphilis requires both experience and resource as well as a determination to neglect no remedy which may be the most suitable for a particular patient. A selection from among modern chemotherapeutic preparations has made it possible not only to disperse with ease the obvious signs of primary and secondary syphilis, but also in most patients to give a good prognosis as regards complete cure. The same prospect cannot be held out in the tertiary affections, but even here progress has been made on unexpected lines. The control afforded by laboratory tests in syphilis has already raised the standard of effective treatment far higher than it is in certain other chronic diseases. It rests now with the clinician to keep a close watch on the future progress of cases with anomalous Wassermann reactions and to trace the early records of those whose death from cardiovascular or other forms of late syphilis testifies to defects in the scheme of treatment to which they were subjected.

THE EVACUATION OF WOUNDED BY AIR.

THE theoretical considerations involved in evacuating sick and wounded by aeroplane in war-time have recently been considered both in this country and in the United States. Practical experience has been gradually accumulating since the war, and has been summarised by General Fritz Bauer, of the Swedish Army Medical Service.[5] He says that there were no organised attempts to use aeroplanes for military medical purposes in the late war, but that by 1925 the French in Morocco and Syria had actually evacuated nearly 3000 cases by air. In October, 1921, six aeroplanes carried 18 seriously wounded men in 35 minutes a distance which by ordinary transport would have taken three days. In Iraq we followed suit, and after various trials of unsatisfactory types of aeroplanes in March, 1924, the Vernont Victoria, which carries 24 sitting or 14 lying, was adopted as a standard type, and air evacuation came to be the normal method employed. It may be said that in countries such as Morocco and Iraq this method has not proved more dangerous or costly than other modern transport, and it has an excellent effect on morale, because it saves lives and reduces suffering. The great development of flying in the United States has led Captain R. K. Simpson[6] to explore the possibilities of the organisation of air transport for the wounded on a really big scale on the outbreak of war. He states that more than a hundred firms are at present engaged on aeroplane manufacture, and points out that while civilian aeroplanes are not suitable for fighting purposes, and civilian pilots would need a considerable period of training to enable them to take the field in war, both aeroplanes and pilots would be immediately available for ambulance purposes. They would operate entirely behind the lines, and so would not run risks from enemy action, and their work would only be interfered with by dense fog. The actual types and equipment of aeroplanes most suitable for ambulance work have lately been discussed by Group-Captain H. V. Wells.[7] Machines of the small 2-seater type have the advantage of needing only a small landing and taking-off space, but they are mostly incapable of taking a stretcher case owing to the cross bracing wires of the fuselage. A hoop system, however, will dispense with cross wires, and we have such a machine in the Fairey III. F. Wells suggests that evacuation by air finds its greatest value in tropical wars.

DIET AND STERILITY.

FERTILITY, both in the animal and vegetable kingdoms, is naturally associated in our minds with an abundance of good nourishment. Among mankind fasting has been practised from time immemorial as an aid to chaste living. The relation between fertility and abundance of food is not, however, by any means a simple problem, and we think at once of the pronounced tendency of our own poorer classes to produce large families in spite of their having a decidedly limited amount of money to spend on food. There is a considerable body of evidence pointing to some relation between the state of nutrition and the degree of fertility. Dr. Donald Macomber,[8] who has made a special point of investigating possible dietetic errors as the cause of sterility in women, has recently collected some of this evidence. Animal experiments have shown clearly that the quality of food eaten may exert a profound influence on fertility, and in the rat a specific accessory factor named vitamin E has been proved essential for normal reproduction. It is possible also that the quantity of food eaten may be of importance. An experiment in undernutrition carried out in the United States during the Great War may have some bearing on the problem. A squad of 12 men belonging to a training school were submitted for a period of four months to a general dietary restriction so that they lost 12 per cent. of their weight. It was noted during the course of the experiment that without exception they ceased to manifest the usual involuntary phenomena of sexual vigour, although they felt fit and were able to carry out all their regular work and exercise. It has been reported frequently that during times of famine the menstruation of women may cease. It therefore seems possible that at the present time, when fashion decrees that women shall be perpetually undernourished, there may be cases of sterility directly attributable to the state of malnutrition. An analysis of the diets of 200 women seeking advice on account of sterility showed that their consumption of protein was 10 per cent., and of total energy value 18 per cent. below the normal standard. These figures by themselves prove nothing, but at least they suggest the desirability of including an inquiry into the dietary habits of those who are seeking a remedy for sterility. There is no definite evidence at present that deficiency of vitamin E determines the occurrence of sterility in women, although it is worthy of note that the diets of the 200 women mentioned above were in many cases found to be deficient in fat-soluble vitamins. Forty of these women became pregnant after receiving advice on how to improve their state of nutrition, and, though it cannot be assumed that the result was always due to changes in dietary habits alone, the treatment of sterility in the future may reasonably include attention to both the quantity and quality of the food eaten.

THE FATE OF PREMATURE INFANTS.

THERE is still much uncertainty about the subsequent physical and mental development of the premature or underweight infant. It is agreed that mortality is high in the first few years of life, but views on the health of those who survive are so conflicting that they scarcely help in the prognosis of actual cases. Sigurd Ranke[1] has lately studied the fate of a series of infants weighing less than 2500 g. at birth, and compares his results with those of other investigators including C. Looft[2] and A. Yllpö, who adopted the same birth-weight as a standard of prematurity. Of Ranke's series of 190 children seen at a children's hospital in Malmö from 1915 to 1924, 35 could not be traced, but as many as 82 (53 per cent.) were known to have died. This percentage is almost identical with that found by Yllpö. Further analysis of these figures showed that 78 of the 82 died in the first year, and that after this age the mortality was not greater than that of full-term infants. Of the 73 children who could be traced and re-examined, Ranke found only four (5·5 per cent. of the survivors) who were classed as mentally defective. This gives a figure of 3·4 per cent. of traced cases surviving the first six months, compared with 7·4 per cent. found by Yllpö. Besides the four aments there were nine children in Ranke's series who were somewhat backward. The incidence of mental impairment is considerably lower than that found by some other authors he quotes. The majority of the premature children traced by Looft after 10 years were found to be retarded, while L. Salomonson records a mental deficiency rate of 21 per cent. On the other hand, H. Finkelstein and others found no cases of amentia. A striking difference in the series of Looft and of Ranke lies in the incidence of Little's disease, which was 18 per cent. in the former and nil in the latter. Ranke gives interesting observations on the subsequent measurements of these children; their weights tended to be at or below the average, and the heights at or above the average, corresponding with the observer's impression of "long, lean and slim" children. The principal fact which emerges from these important investigations is that prematurity, though often associated with amentia, is not an actual cause of it. The causes of prematurity itself are obscure and probably numerous, and the subsequent characteristics of the infant will be conditioned by these varying causes rather than by the state of maturity reached at birth.

A NEW KIND OF HISTORY.

"Some day a man will write a new kind of history. Its keynote will be the shaping of human destiny by disease, and, let us hope, the guidance of this destiny by virtue of the control of disease."

WITH these remarks Dr. Allen Krause opened his Hermann M. Biggs Memorial Lecture for 1927; the materials for such a task are obviously considerable, and Dr. Krause himself made no little use of them in the lecture which has now been reprinted as a booklet.[3] Using the social history of the United States as his milieu he sketches the long struggle which has gone on to obtain control of the tuberculosis problem since the early days of the public health movement. Phthisis was uncommon in America at the end of the eighteenth century, but by 1828 it was increasing "with fearful strides." Brought in by the early settlers, Dr. Krause thinks that the disease was quite likely held almost under cover as long as a sparse agricultural economy existed. Even in the developing villages and towns phthisis was probably uncommon, but growing cities began to bring it into notice, and by the time the manufacturing side of the nation had made its presence felt at the beginning of the nineteenth century, tuberculosis had become a national menace. Dr. Krause has some astonishing facts to relate of the industrial revolution in America, but although the scene is laid on the other side of the Atlantic the outlines of the picture seem to be strikingly similar to our own; James Truslow Adams and Josiah Curtis tell much the same tale as Charles Kingsley and Arnold Toynbee. Ill-ventilated factories, crowded dwellings, all the insanitary conditions which were the concomitants of the early days of industrialisation, helped to create a high tuberculosis death-rate. It was an age of enormous industrial expansion and an accelerated impulse towards urbanisation, and according to Dr. Krause, "by 1850 it was plain that mid-century industry was the handmaid of tuberculosis." He then goes on to show how public health machinery is triumphing, slowly but surely. In the early days of the industrial revolution, tuberculosis was an urban malady and an urban problem; the factory system was in process of evolution, and living conditions did not keep pace with them. Now the position is changed. The towns are out-stripping the country and if civic sanitation continues to progress at the present rate, tuberculosis is likely to become a rural rather than an urban problem.

THE INTRADERMAL TEST FOR HYDATID DISEASE.

EIGHTEEN years have elapsed since Casoni described his intradermal test for hydatid disease, and in the intervening period various modifications in its technique and interpretation have been made. The most important development has been an appreciation that the reaction manifests an immediate as well as a delayed phase. Casoni originally injected 0·5 c.cm. of hydatid fluid intradermally and noted the marked erythema of the skin, the infiltration and the puffy swelling of the subcutaneous tissues which appeared some hours later in hydatid cases. This phase is now known as the delayed reaction. Magath in 1921, using a technique similar to the Pirquet test, observed rapid wheal formation and cutaneous erythema following the application of hydatid fluid to the scratched skin in three people harbouring hydatid cysts, and in the following year Ithurrat and Calcagno reported a similar type of response occurring within a few minutes of the intradermal injection of a similar antigen. Sixty-three of their series of 65 patients suffering from hydatid gave an immediate response, and only 4 out of 127 cases subjected to the test failed to correspond with the operative findings. Later in Australia Kellaway, Dew, and Williams studied both phases of the reaction at the Walter and Eliza Hall Research Institute and came to regard the immediate reaction as of great diagnostic value. Immediate wheal formation, however, was noted in the absence of demonstrable hydatid infestation in cases showing jaundice, urticaria, and generalised skin diseases. This year two additional papers have originated from the same Institute, the first being a critical analysis by K. D. Fairley[1] of the results of the test obtained over a period of five years. Exacting criteria of diagnosis were enforced, all doubtful cases being rejected from the series. In hydatid patients tested before their first operation 82·9 per cent. showed the immediate reaction and 40·4 per cent. the delayed response. The anatomical location of the cyst was found to exert little or no effect, but its pathological condition definitely influenced the reaction, since 92·0 per cent. of cases with ruptured or suppurating cysts yielded positive results compared with 77 per cent. in which these complications were absent. On the other hand, 35 out of 87 cases (40·2 per cent.) which gave an immediate wheal failed to show any evidence of hydatids on detailed investigation, and the justifiable conclusion was reached that no surgeon should operate solely on the basis of an immediate reaction. No evidence of hydatid was found in 96·8 per cent. of hospital patients in whom wheal formation was absent and a negative reaction came to be regarded as highly important, though not infallible, evidence in excluding echinococcosis. In Fairley's opinion this constituted the chief clinical value of the test. During the post-operative period immediate reactions were recorded in 90·2 per cent. of patients. Recent rupture of the cyst with consequent temporary desensitisation was sometimes found to be responsible for negative findings. When no other cysts were present the reaction often persisted for years, but its continued absence in any patient showing a positive result before operation was regarded as evidence of cure.

[1] Fairley, K. D.: Med. Jour. of Australia, 1929, i., 472.

The second paper, written conjointly by K. D. Fairley, N. H. Fairley, and F. E. Williams[2] was the outcome of an inquiry into the causation of immediate reactions in patients showing no other evidence of echinococcosis. More exacting standards and controls for the test are recommended with the object of diminishing or abolishing the growing list of pseudo-reactions reported by numerous observers. Accurate measurements of the immediate wheal and of the area of infiltration in the delayed reaction are shown to be essential. It is pointed out that in the past the results have been classified as "positive" or "negative" largely on the impressions of what constituted a reaction or a failure to react, and as these conceptions varied with individual observers no accurate comparison of results is possible. Guisti and Hugg first reported the presence of pharmacologically active substances in samples of hydatid fluid, and it is now shown that such fluids may occasionally give rise to either direct or indirect types of reaction in normal individuals. In consequence it is urged that fluids be tested on a series of normal individuals in order to exclude pharmacologically active substances as well as standardised for antigenic potency on those harbouring hydatid cysts.

To perform the test 0·25 c.cm. of standardised hydatid fluid is injected into the dermal layer of the skin covering the outer surface of the arm, a similar injection of normal saline solution (0·9 per cent.) serving as a control a few centimetres away. Care is taken to ascertain that this area has not been previously tested. If so, another site must be selected since local sensitisation was proved to result in a normal person from the repeated injection of hydatid fluid into an area of skin ringed with silver nitrate. In recording results wheals the size of a shilling (diameter 2·4 cm.) are regarded as positive, those not exceeding sixpence (2·0 cm.) as negative, and those of intermediary dimensions as of doubtful significance. In the latter case the test is repeated. Outrunners resembling pseudopodia are taken into account in making measurements. When the control injection of saline produces a wheal exceeding 2·0 cm. in diameter, the patient is rejected as an unsuitable subject for the test, and the same applies if there is a triple response to the stroke test (Lewis). A wheal even of the dimensions mentioned, however, was not found to be pathognomonic of echinococcosis. Certain other fallacies were shown to exist, and in any case presenting a positive reaction further investigations are advised. Filtered sheep serum (0·25 c.cm.) is injected intradermally in order to exclude sensitiveness to sheep serum proteins, for the data presented clearly demonstrate that hydatid fluid from ovine sources contains sufficient host protein to produce positive reactions in patients not infested with hydatids, but sensitive to sheep serum. Finally, the group reactions attending concomitant helminthic infestation receive consideration. Both immediate and delayed reactions were observed in non-hydatid cases harbouring other tapeworms such as *Tænia saginata*, and for this reason a search for intestinal helminths may be indicated. In nematode infestations less conclusive evidence of group reaction was presented.

The new facts elicited by these important investigations clearly indicate that the intradermal test affords no short cut to diagnosis. For many years it has been appreciated that a specific antigen-antibody reaction underlies the various biological tests for echinococcosis. In the intradermal test, unfortunately, an additional vascular mechanism is involved. Increased permeability of the capillaries with fluid transudate underlies wheal formation, and according to Lewis this in turn is dependent on the liberation of "H substance" during the intracellular union of antigen and antibody. Be this as it may, the vascular factor introduces its own peculiar fallacies, the elimination of which calls for both skill and judgmention the part of the practitioner employing the test. Serological reactions, like the complement-fixation and precipitin tests, are conducted in vitro and do not suffer these limitations; of necessity they must remain the most reliable of the biological aids to diagnosis in those countries where hydatid is endemic.

CLEAN AIR.

THE National Smoke Abatement Society has produced a new journal called *Clean Air*. The first issue, dated Autumn, 1929, is sent forth with good wishes from many eminent people, and contains a number of articles on the purification of the atmosphere in our cities. Smoke was long regarded as the inevitable accompaniment of industry, and the possibility of freeing the air from it was at first the fad of a few. The idea has, however, taken firm hold and may very soon become the normal expectation of us all. It has been demonstrated over and over again in industry that the most hygienic method is the most economical, and cleansing of the atmosphere obeys this law, for smoke is simply wasted fuel. There are three principal lines along which to proceed with smoke prevention: gas, electricity, and smokeless fuels like anthracite. *Clean Air* contains an article on the use and development of gas in industry, giving examples of the innumerable directions in which gas can be economically used in various trades. The director of a research institute in America has estimated that the potential market for industrial gas is at present only 2 per cent. saturated. Another article deals with the uses and development of electricity in industry and stresses its very wide range of application, its precise and positive control, the exceptional uniformity of temperature which it yields, and the reduction to a minimum of labour requirements. It must be admitted, however, that the private consumer is the chief offender against the purity of the atmosphere; regulations have already gone far towards abolishing the cloud of smoke that used to belch forth from factory chimneys, but every small house contributes its little wisp to the fog that lies over London. The annual review of domestic heating given in the new journal suggests that those who long for the comfortable sight of an open fire burning in the grate should have their wish—more or less—by burning either anthracite or high quality gas coke in their grates. The low-temperature carbonisation fuels have saved the open grate from the condemnation with which it was threatened by the reformer, and though it must be admitted that such fuel still remains rather more expensive than coal, it reduces dirt and labour in the house as well as smoke outside it. Much experimental work requires to be done on these combustibles, and there is also scope for improving the general temperature of British houses by central heating or by insulation, so that the amount of fuel burned in the open grate is reduced. There is a very great deal to be said for the abolition of smoke, and practically nothing except prejudice or sentiment (and the price of smokeless fuels for those who want the open grate) to be said against it. We hope that the new journal will receive the support for which it asks and will be able to carry the campaign for clean air into the homes and factories of the whole country.

---

[2] Fairley, K. D., Fairley, N. H., and Williams, F. E.: Ibid., 1929, ii., 320.

WE regret to announce the death of Sir Sidney Alexander on Dec. 9th, at the age of 66. From 1910 to 1920 he was Mayor of Faversham, where he practised for many years before taking up consulting work in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Vice-Admiral Arthur Gaskell, C.B., O.B.E., Medical Director of the Royal Navy following precedent, has accepted an extension of his appointment for one year from June, 1930, when he will have completed the ordinary term of three years, having succeeded Sir Joseph Chambers, K.C.B., C.M.G., in 1927. Surg. Vice-Admiral Gaskell, who is 58 years of age, joined the Navy in 1893. He was made C.B. for his services with the Royal Naval Division at the Dardanelles where he was A.D.M.S. Afterwards he was in charge of the hospital ship *Soudan* and later head of the R.N. Hospital at Simonstown.

Surg. Comdrs. A. R. Fisher and T. R. L. Jones are placed on the Retd. List at their own request, with the rank of Surg. Capt.

Surg. Lt.-Comdr. F. G. Hunt to be Surg. Comdr.

The following appointments are notified: Surg. Comdrs. E. Moxon-Browne to *Malaya*; G. L. Ritchie to *Greenwich*; and C. M. R. Thatcher to *London*. Surg.-Lts. J. J. Mason to *Egmont*, and J. W. L. Crosfill to *Concord*.

ROYAL ARMY MEDICAL CORPS.

Lt. H. McNeill relinquishes his tempy. commn.

ARMY DENTAL CORPS.

Maj. F. W. Shilton retires on account of ill-health receiving a gratuity.

TERRITORIAL ARMY.

Maj. A. P. Draper, R.A.M.C., vacates the appt. of Divl. Adjt., 52nd (Lowland) Div., T.A.

Lt. G. Williams to be Capt.

Supernumerary for service with O.T.C.—Lt. G. P. Crowden to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. W. T. Gardiner, from Active List, to be Maj.

Capt. W. G. Saunders, from Active List, to be Capt.

Lt. R. L. Turner, from Active List, to be Lt.

INDIAN MEDICAL SERVICE.

Lt. D. P. Lambert to be Capt.

The undermentioned officers relinquish their temp. commns.: Capt. Rama Shanker Varma, and Lts. Bonbehari Bhattacharji and Mazhar Hussain Shah.

COLONIAL MEDICAL SERVICES.

The following new appointments have been made by the Secretary of State for the Colonies:—Dr. H. G. Harvey, Medical Superintendent, King Edward VII. Memorial Hospital, Bermuda; Dr. W. B. Sutherland, Medical Officer, Malayan Medical Service, Federated Malay States; Dr. E. Holmes, Medical Officer, Iraq; Major J. W. C. Stubbs, Inspector of Medical Services, Iraq Army; Captain G. A. C. Gordon, Medical Officer of Health, Nigeria; Dr. H. G. Pritchard, Medical Officer, Nyasaland; and Dr. G. Q. Chance, Medical Officer, Malayan Medical Service, Straits Settlements. Dr. G. R. Baxter has been appointed Medical Officer of Health, and Dr. W. R. Little, Medical Officer, on the West African Medical Staff.

ROYAL SEA BATHING HOSPITAL, MARGATE.—The 138th annual report of this hospital states that the average daily number of occupied beds was 301, and the average cost per occupied bed was £127 6s. 11*d.*, as against £134 13*s.* 7*d.* in 1927. Portions of the building which are built of red brick are being so much affected by the salt-laden atmosphere that the bricks are crumbling and in some cases completely decayed. Heavy expenditure will be needed to check the degeneration.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

LVI.

INTERPRETATION OF RADIOGRAMS OF THE ALIMENTARY TRACT.

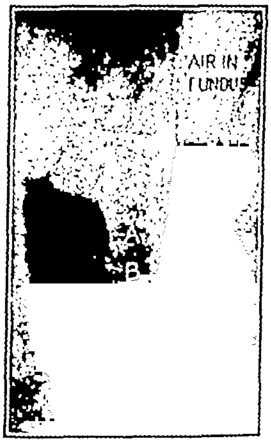
PART III.*—THE DUODENUM.

RADIOLOGISTS talk of the first part of the duodenum as "the cap." It looks and behaves quite differently from the rest of the duodenum. Functionally, apparently, it is different, for it fills up with opaque food into a triangular, cocked-hat shaped shadow, poised on top of the pylorus, usually pointing towards the gall-bladder; whereas the food passes rapidly through the second and third parts and is divided up by the muscular action of its walls, so that no definitely outlined shadow is seen (Fig. 17). In stout patients the cap is sometimes turned backwards and lies almost directly behind the stomach. This disposition greatly increases the difficulties of palpation and also of obtaining films, for it necessitates an oblique or even a transverse illumination.

Duodenal Ulcer.

The duodenal cap usually fills satisfactorily, at any rate if we are patient and wait. But if there is irritation it is sometimes extremely difficult to get the cap outlined. With patience and the assistance of manipulation it is usually possible to hold some opaque food in the cap and to manipulate it sufficiently to demonstrate that the outline is not persistently deformed. Ulceration of the duodenum is almost confined to the first part (90 per cent. or more), and whenever there is ulceration there is *persistent* deformity of the cap shadow (Figs. 18 and 19). This deformity is largely due to spasm, and the resultant picture varies widely according to the site of the ulcer and the degree of spasm. Every attempt should be made to demonstrate the actual crater of the ulcer. This is not by any means always possible; yet, apart from the demonstration of the crater, I do not think that we are justified in making an absolutely positive diagnosis. With a deformity that is persistently the same, the probabilities are very high that it is due to the presence of an ulcer, but it might be caused by adhesions, and, personally, I reserve the definite diagnosis for the cases in which the ulcer crater is detected. Every observation on the duodenum and also on the stomach, whether positive or negative,

FIG. 17.



Normal duodenal cap (A). The stomach is of the long type and the cap points vertically. Its upper limit is on the level of the crest of the ilium—i.e., the duodenal attachments have allowed it to descend to compensate for the "gastroptosis." Note the large quantity of air in the stomach. Probably a nervous type of female subject who is inclined to air-swallowing and consequent eructation. Note also the food passing through the second and third parts of the duodenum. In this and subsequent figures B = pylorus.

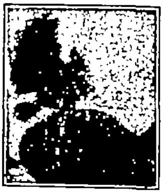
---

[*] Parts I. and II., on the Œsophagus and the Stomach respectively, appeared in THE LANCET of Nov. 30th and Dec. 7th. The Intestines will be dealt with in subsequent issues.

should be confirmed when the patient comes up for examination on the second day.

Beyond the duodenal cap the opaque food is quickly broken up into fine division. Sometimes there is accumulation in the loop of the duodenum—duodenal ileus. This may or may not be pathological, due to some kinking or drag at the duodeno-jejunal flexure, or other cause of obstruction, but unless it is well marked it is wise to regard it as of no pathological significance. As often as not we do not find it when we re-examine, particularly if the circumstances are more normal than at the first examination. Rapid emptying of the stomach often gives rise to such an appearance. Certainly a slight degree of duodenal ileus may be disregarded as a guide to surgical interference.

FIG. 18.



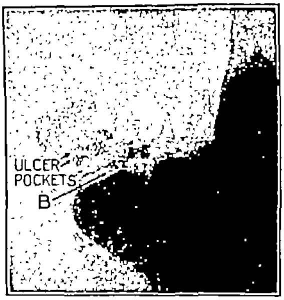
Deformity of the duodenal cap—a typical type of deformity.

New growths of the duodenum are extremely rare—an interesting fact considering the extraordinary prevalence of ulceration. There is certainly no tendency of duodenal ulcer to become malignant. Whether the very similar peptic ulcer of the stomach is as liable to malignancy as was formerly supposed seems to be open to question. X ray observations are all against such a sequence except in very rare cases.

Diverticula.

Diverticula of the duodenum are comparatively common and they are liable to give rise to symptoms that are indistinguishable from those of duodenal ulcer. The pocket of the diverticulum, which is usually about the size of the end of a finger and arising about the junction of the first and second part, is more readily identified on the screen than on the X ray film. Diverticula may occur in other parts of the duodenum (Fig. 20) and also in the small intestine, but they are not so common and are probably less often associated with symptoms. A condition of the first and second part of the duodenum which may give rise to symptoms of duodenal ulcer and to appearances that are rather similar to those of a diverticulum is caused by a dropping over and twisting of the junction of the first and second parts, an appearance that is not readily appreciated on the screen and not always recognised as a possibility on the operating table.

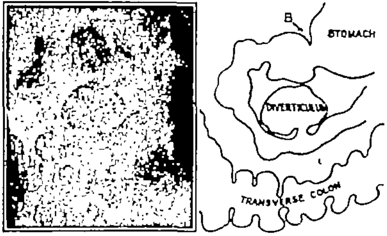
FIG. 19.



Deformity of the duodenum showing the pockets of two ulcers near the apex of the cap.

Adhesions about the gall-bladder are common, and many of them give rise to deformities of the duodenum which are almost, if not quite, indistinguishable from those caused by ulcer. Palpation of the food in the duodenum and the detection of undue fixation is the only way in which one can attempt to arrive at a reasonably accurate diagnosis.

FIG. 20.



Large diverticulum of the third part of the duodenum—an unusual site. Patient recumbent and stomach only partially filled. Normally the food passes rapidly through the duodenum. In this instance the radiologist by his manipulation has dammed the third part and forced food out of the stomach in order to obtain this radiographic effect.

SOME OBSERVATIONS ON SCANDINAVIAN SURGERY.

BY T. HOLMES SELLORS, B.M. OXF.,
G. H. HUNT TRAVELLING SCHOLAR, UNIVERSITY OF OXFORD; SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

II.

VASCULAR SURGERY.

Arterial Embolism.—The clinical and operative study of arterial embolism was greatly advanced by a paper from Prof. Einar Key, of Stockholm, in 1922. This year he has published a further report in which the results of 213 cases have been collected. This includes 17 cases of his own. The removal of emboli has become a standard surgical procedure, and the diagnosis is based on the general condition of the patient—i.e., possible existence of heart disease, *&c.*; and the site of the initial pain, lividity, and loss of pulse below this region give an accurate localisation of the embolus. The operation is usually performed almost exactly over the site, and the time factor is of great moment on account of thrombosis behind the embolus. The majority of these cases originate in heart lesions, but arterial disease may also play some part. The operation of embolectomy should be performed as soon as possible after diagnosis, so as to check the obliteration of collateral circulation by back-spread of thrombosis. Also there is the risk of malnutrition with subsequent ulceration and secondary thrombosis at the site of the embolus, which is most commonly at a bifurcation of two vessels.

The affected artery is exposed, pulsation is absent, and the rubber-like clot can be felt blocking the lumen. Soft clamps are applied beyond the limits of the clot and the intervening artery is incised. The clot is gently removed, and release of the clamps alternately will demonstrate freedom of the blood stream. Sutures of very fine vaseline silk are used to repair the incision. There has been no record of stenosis or aneurysm which can be attributed to the sutures. The prognosis ultimately is not satisfactory in cases with an underlying heart lesion, though a very large number may be said to be cured as regards their embolism. The figures from Prof. Key's paper show that, if the operation is performed under ten hours, 51 per cent. of the cases give good results. Over ten hours a good result is only obtained in about 23 per cent. of the cases. The frequency of embolism is, roughly, the femoral, common iliac, popliteal, bifurcation of aorta, brachial and axillary arteries. On the whole, embolism in the arm gives the best results, since the collaterals are freer, and even if secondary thrombosis occurs, the interval of freedom resulting from operation may be sufficient to allow the establishment of an efficient circulation.

Results from aorta are, generally speaking, bad, whereas embolism of the leg arteries gives fairly good results under ten hours. Naturally the state of the vessel itself is a big factor in the prognosis, but age is not necessarily a contra-indication to the operation, which can, in the majority of cases, be performed under local anæsthesia.

Venous Thrombosis.—Thrombosis of the femoral and iliac veins as a post-operative complication is common in Scandinavia as compared with England. The reason of this is not clear, since all commonly recognised causes have been countered as far as possible. It is said that the incidence in the north of Sweden is not as great as in the south, where the type of individual is heavier in build. There is certainly a relative tendency to the thrombotic condition in big, fat people, who have been submitted to an incision in the anterior abdominal wall, but no amount of breathing exercises, massage, or movements of the lower limbs seems to have much effect in diminishing the frequency of this condition. Prof. Nyström, of Upsala, has made some preliminary observations on the blood-platelet count, and by daily estimation is frequently able to predict, but not prevent, the onset of thrombosis.

Pulmonary Embolectomy.—From the frequency of venous thrombosis it may be gathered that pulmonary embolism, too, is not rare. To meet this dramatic emergency a modification of Trendelenburg's original operation is being practised. To date 20 failures have been reported, as against seven or eight complete successes, but it is interesting to note that there had been no complete success reported up to 1924. The time factor between the actual embolism and removal of the clot imperatively demands emergency measures. The surgeon may not be at hand, and consequently, in the majority of Scandinavian clinics, the first and second assistants have been trained to perform the operation if occasion arises. Where possible, at the onset of an embolism, the patient is hurried to the operating theatre, where sterilised instruments are kept constantly in readiness. The operation itself is not started until it is absolutely certain that the heart will stop in one or two minutes, or has already stopped. Anæsthesia is unnecessary; a vertical incision over the second to fifth costal cartilages is made, and by division of the cartilages the pericardium and pleura are exposed. The pleura is pushed aside, and the upper part of the pericardium incised. A big clamp is passed through the transverse sinus around the aorta and pulmonary artery controlling these vessels, and the base of the pulmonary artery itself is then opened and endeavours are made to extract the clot. Sometimes the clot comes free with gentle application of forceps; at other times a sucker may have to be used. Adrenalin is injected into the base of the aorta so as to reach the coronary circulation, and the control clamp is freed while the incision in the pulmonary artery is held. If the heart starts beating the hole in the pulmonary artery is sutured, the tissues are anæsthetised, and the original incision repaired. I saw Prof. Nyström's second successful case two or three weeks after the operation, and she was apparently making a satisfactory recovery. It is certainly a field of surgery which has considerable possibilities, since the proportion of successes, even allowing for unreported failures, is very encouraging, the more so when it is realised that the cases were not operated on until the heart had ceased to beat. A paper containing details of the operation as well as a full and lucid account of arterial embolism has been published this year by Prof. Einar Key in *Ergebnisse der Chirurgie*, March 22nd, 1929.

RADIOLOGICAL CONGRESS.

LONDON, DEC. 4TH–6TH, 1929.

THE annual meeting of the British Institute of Radiology incorporated with the Rontgen Society was held in the Central Hall, Westminster, from Dec. 4th to 6th. In the course of the meeting the tenth Mackenzie Davidson Memorial Lecture was delivered by Prof. GOSTA FORSSELL, in charge of Radiumhemmet, Stockholm, on the Radiotherapy of Malignant Tumours in Sweden[1]; and the twelfth Silvanus Thompson Memorial Lecture by Prof. A. S. EDDINGTON, F.R.S., on X Rays in the Stars. A number of technical papers were read, among them one by Dr. FFRANGCON ROBERTS, which appears in full on another page, and several discussions took place on debatable questions of the moment.

Dr. L. A. ROWDEN being in the chair, Dr. G. B. BATTEN opened a discussion on the

Requirements of Clinicians from Radiologists and Vice Versa.

He said that "radiologist" had come to mean a doctor who used X rays for diagnosis or treatment, while "radiographer" meant an unqualified person who used X rays. The requirements of clinicians from radiologists should be exactly the same as their requirements from all other specialists: such aid as would help them to diagnose and treat their patients in the best possible way. In many cases a team was necessary. The clinician most of all required really good films with a careful, well-considered report. The radiologist required from the clinician everything that any other specialist would require to help him to elucidate the problem for correct diagnosis. The clinician must take the radiologist into his confidence and state in what directions help was needed. There were very rare cases where a patient should be sent without any information; but the number so sent in the patient's real interests was very small. The radiologist should treat the clinician in a truly professional and consultative way, and in difficult cases should try to arrange a personal discussion. He ought to have beds of his own. His relations with his patient should be strictly ethical and as wise and reticent as possible, and he should never give away the clinician. The unsatisfactory clinicians met in actual practice could be divided into (1) those who regarded radiology as a joke—these could be allowed to die out; (2) those who regarded it as unimportant and radiologists as opponents rather than helpers—these were diminishing; (3) those who belittled radiologists and withheld knowledge about the patient; (4) those who wanted to interpret the radiograms themselves; (5) those who expected a non-medical radiographer to interpret X rays; (6) those who wanted the films interpreted as pictures only, without any opinion about the condition of the patient; (7) those who left too much to the radiologist and ignored the clinical aspect of their cases. Radiologists were of two kinds—pure radiologists and practitioners taking radiology as their specialty. It took a population of 50,000 in a town to maintain a pure radiologist. The relation of the general practitioner radiologist with his clinical colleagues was less simple than that of the pure radiologist, and he must be particularly ethical in his conduct. The radiologist must use all the knowledge he had, apart from the

---

X ray showings. The clinician could not properly dictate treatment to the specialist unless he was himself a skilled electrotherapist. The radiologist must be right, and to be right he needed experience, good films, careful technique, and good apparatus.

Dr. D. D. MALPAS said that he parried patients' questions by explaining that he had not got a finished story until he had seen the last film.

Dr. A. J. ILES said he told patients that only a bad judge would condemn the prisoner before he had all the evidence. Radiologists were entitled to loyalty which they did not always get from clinicians.

Dr. S. MELVILLE said he had suffered in the past from the difficulties Dr. Batten had described, but had noticed a great improvement of recent years in the attitude of clinicians. The fault lay nowadays, he felt, with the radiologist, who sometimes foolishly encroached on the province of the clinician and offered indifferent work. He must offer really good work and refrain from dogmatising unless certain.

Dr. GRACE BATTEN related some of the extraordinary requests and inadequate requisitions she had received from clinicians. All these people triumphed over or blamed the radiologist for not making a correct diagnosis.

Dr. JOHN MUIR said that the only way to get peace in this world was to suffer fools gladly, and urged a conciliatory attitude towards clinicians. If the practitioner with his living to make could save his face by blaming the radiologist it was but human to do so. The radiologist should never be afraid to say he did not know.

Dr. FFRANGCON ROBERTS agreed with Dr. Muir and had no complaint to make of his hospital colleagues. The panel practitioner must be credited with doing his best under difficult circumstances. What to tell the patient constituted a most difficult problem, which depended largely on the kind of patient and the kind of doctor. It was no use beating about the bush with intelligent patients. Sometimes a patient moved into a new district from which a new doctor would write or wire for the films of an earlier examination; this was quite wrong, and the new doctor had no right to anything but a copy of the report.

Dr. MALPAS agreed that radiologists often made trouble for themselves and that a more conciliatory manner would be better.

Dr. F. I. JUPE was pleased to think that the *mariage de convenance* between clinician and radiologist was being changed to a love match, and that both parties were coming to look on the patient as their common child.

Dr. ILES spoke of the difficulty of deciding to whom the film by right belonged.

Dr. MILES asked to what extent clinicians should be allowed to see the film. He thought the radiologist's report should be enough, except when a surgeon or dentist had to operate as a result of the report.

Dr. G. HARDMAN said the radiologist ought to give the report to the new doctor on request. He thought that in the main radiologists received great courtesy from their colleagues.

Dr. A. MACGREGOR thought the clinician often insisted on a definite statement when the radiologist was unprepared to make one.

The CHAIRMAN thought it was a question of give and take; when a radiologist disregarded the clinical aspect of his cases he was rapidly degenerating into a radiographer. He must go into the history and make an examination. He (Dr. Rowden) never let films go out of his possession; if he did they never came back. The film was the property of the person who took it, but the patient had a perfect right to hear the interpretation.

Dr. BATTEN, briefly replying, said that the films belonged to the radiologist who had ordered them to be taken or to the hospital, but the doctor had a right to see them and the patient had a right to know the report.

Aspects of Radiation Therapy.

Prof. S. RUSS spoke of intensity relations, pointing out that greater intensities produced more violent reactions. Radiation of any kind released electrons from the medium and might or might not produce clinical changes. The liberation of electrons was a disturbing factor, though a perfectly normal process in the human body, which spontaneously liberated about a million ions a minute. The rate of release need not be very great in order to produce appreciable effects—something of the order of one electron per cell per second.

Mr. GEOFFREY KEYNES spoke of the radiological treatment of carcinoma of the breast. Radiology in the past had been confined to four classes of patients—those who refused operation; those treated prophylactically after operation; those treated for recurrences after operation; and the hopelessly inoperable. Comparison between radiology and surgery could only be based on operable cases. Surgery at St. Bartholomew's had not been satisfactory, and the successful eradication of local recurrences by radium had led to the treatment of primary cases. Great success had followed in a series of 145 cases, all of which had been carefully documented. Good results had been obtained in 45 out of 67 patients up to the end of 1928 and half of them were free from demonstrable signs of disease. Of 26 inoperable cases a good result was recorded in 12, and six of them were apparently cured. It was unlikely, though possible, that X rays would have been equally successful with so little damage. In the early case it was possible to promise almost with certainty that in five months after a single radium treatment the breast would be apparently normal. X rays had a part to play in supplementing radium treatment in the few cases where it had proved inadequate.

The Relative Value of X Rays and Radium.

Dr. N. S. FINZI dealt with the relative value of radium and X ray therapy in malignant disease. Both were valuable, and it was curious how seldom patients took a radiological as well as a surgical opinion. During 20 years' of experience he had seen improvement follow each increase in voltage and filtration of X rays, and the limit of this improvement had by no means been reached. For some cases radium was more valuable, for some X rays, and for others both. Radiologists should be fully acquainted with both agents. The importance of radical X ray treatment was not adequately appreciated; the results fully justified the courage required on the part of radiologist and patient. Many surgeons were just learning to apply radium; it was to be expected that they would have many failures. The radium bomb had many of the advantages of X ray treatment, but the rays were more penetrating and probably more efficient physically and biologically. The greater homogeneity obtained with X rays must be balanced against the greater effectiveness of radium gamma rays. In very radio-sensitive growths X rays were the treatment of choice every time, even in the skull. For very small growths, tending to remain localised, radium was preferable. For very radio-resistive cases radium was to be selected if surgery or diathermy was inapplicable. By increasing the time factor and decreasing the intensity better results could be obtained in many cases. The position of the growth was important. In the mouth and upper air passages the best results had been obtained with X rays alone or a combination of X rays and radium. Seeds in the local growth and a radium needle barrage for the cervical glands had given good early results, but the cases would probably show recurrences. The radium bomb through six points of entry would probably prove eventually to be the ideal application. In growths of the cervix radium for the growth and X rays for the glands were best; after X rays alone there was a tendency to recurrence. In rectal carcinoma radium seemed definitely better than X rays. If the mediastinum were involved in breast cancer X rays might still give good results, and they might do wonders for early cases. With the use of radiations for operable growths a great change had come over the prospects of the patient. Skill varied, and counted for a great deal.

Dr. **Malcolm Donaldson** said that for cancer of the cervix at St. Bartholomew's about 5 mg. of radium element, split up into 20–25 needles, was inserted all round the growth and left for 144 hours. He showed figures from various centres; the survival rate for the needle technique was not quite so good as for other methods. Needles seemed to be unsatisfactory for deeper parts of the growth. He therefore proposed in future to supplement the Stockholm technique with, first, intra-abdominal radium and, secondly, X ray treatment. He reviewed the 34 cases he had treated with intra-abdominal radium, and declared that the method was worth continuing. He now treated carcinoma of the vulva with very small intensities for two or three weeks; the primary results had been astonishing. The time factor was also important in cancer of the body. In non-malignant conditions the only problem that arose was to decide which patients could justifiably have their ovaries destroyed. Larger doses might perhaps reduce the menopausal symptoms.

Dr. J. E. **Lynham** spoke of the association of radium and X rays in the treatment of malignant disease. Radium undoubtedly gave results rapidly in some cases, but the final results of X rays were quite as satisfactory; the two agents were supplementary. Permanent success after radium only followed when the disease was localised, and was comparable with surgical success except that the cases treated by radium were inoperable. When the disease had become generalised even local cure could not be obtained, and when recurrence developed in patients previously doing well it was usually a sign of general activation of disease all over the body. There was no means of telling whether or not the disease had become generalised in any particular case. Extension by the lymphatics could be prevented by prophylactic irradiation by radium barrage, radium pack, or systematic X ray applications. Surgically treated cases should be followed up by periodic X ray or radium treatment to the site of the original tumour and to the related glands. As a matter of physics as well as of clinical experience, X rays and radium tended to approach each other as time went on, and the best results would be attained by combining or alternating them.

Use and Abuse of Radium Needles.

Prof. F. L. **Hopwood** read a paper on behalf of Miss F. E. Smallman and himself, and dealt with the economic aspect of his subject. At St. Bartholomew's it had been found that half a gramme of radium, distributed in 222 needles and eight other containers, could be used for 800 patients in a year. Needles of 1 mg. and 2 mg. radium element content were best for a general hospital, and an average yearly efficiency of use of 50 per cent. or more should be considered satisfactory. Long needles were much more valuable than short ones; there was a marked gain in mechanical strength if 0·6 mm. of platinum were used for the walls instead of 0·5 mm.; and needles used for surface application were less liable to damage than those inserted into malignant growths. Every trivial injury should be taken seriously and the needle set aside for immediate repair. The weakest spot was the eyelet, and a new and stronger type of eyelet had recently been introduced. Leakage from damaged needles was rare if they had been gold-soldered, but was such a nuisance that needles should be periodically tested. If any loss was suspected a visual and electroscopic search should at once be carried out on all refuse and laundry, but containers which had passed through an incinerator might be negative to the electroscopic test owing to melting of the solder seal. During ten years St. Bartholomew's had lost track of three needles, containing 3 mg. of radium.

Dr. **Rowden** thought that the kind of ray which would alter cell activity was the kind of ray that would be absorbed by the cell; the short-wave ray in its passage through the cell generated secondary rays which were absorbed. Superficial growths would disappear very rapidly under soft ray treatment; which ray was to be chosen?

Prof. **Hopwood** replied that the question was not simple. Experimentally the type of damage produced by the two types of radiation were almost indistinguishable. The type of ray chosen must be the *one that got to the required spot, but time and intensity* reactions also came in. The rate of absorption depended on a number of factors.

THE ANNUAL DINNER.

The annual dinner of the Institute was held on Friday, Dec. 6th, at the Trocadero, London, the President of the Society, Mr. C. Thurstan Holland, taking the chair at a large assembly. After the loyal toasts Mr. Cuthbert Andrews proposed the Prosperity of the Institute, in the course of which he detailed regrets at the changes in the management of the Institute, which had occurred since his own retirement from many offices, feelings which, he said, were shared by other recently retired officers. He pointed out that since the affairs of the Institute were no longer under their direction, an unpicturesque sense of order had got into the place, in accordance with which letters were now answered and even filed, financial records were kept in account books, and dark rooms had become dark. He lamented the good old days and left the President to explain the situation. Mr. Thurstan Holland, in reply, said that this, he thought, would be positively his last appearance as a President. The situation in which he found himself had occurred thrice before, twice in connexion with one of the bodies composing the Institute, and once at an International gathering. Now, he said, there was nothing further left for him to do officially, *unless radiological activities should be opened to those* who were translated to the stars, a terrible prospect, which had been held out before them during their conferences by Prof. Eddington. In respect of the meeting just held he was justified, he said, in regarding it as a great success, as the high-class papers that had been read revealed the extending possibilities of radiology. But he pointed out that in regard to the therapeutic relation of radium to cancer, the belief that a cure for cancer had been found was unjustified, though radium was now of such immense assistance, a view that had been expressed by their distinguished guest, Prof. Gösta Forssell, in the Mackenzie Davidson Memorial Lecture.

The toast of the Guests was proposed by Major C. E. S. Phillips, who spoke of the progress of the Institute and of the early British work in radiology, in founding the first society, and issuing the first journal devoted to the subject. Prof. Eddington, in an amusing reply, described himself as a celestial astronomer, and while testifying to the value of X rays to the star doctor, said that the celestial astronomer could not get much further than the terrestrial physician—that is, he could diagnose but must leave the rest to Nature. In illustration of the part that radiological methods might play in astronomy, he said that certain dwarf stars, which formerly were ruddy had become pale, and through radiology it had been shown that this was due to an increase of internal density; and he imagined the case of a famous astronomer who announced to his wife that he had detected a star of unique density and that, to do her honour, had called it after her. Mr. Donald Armour, President of the Medical Society of London, and Dr. G. W. C. Kaye, a late President of the Institute, also replied.

The Health of the President was proposed by Prof. Gösta Forssell, and after a brief reply from Mr. Thurstan Holland, a dramatic skit, described on the programme as a "surprise item," was rendered by the author, whose name did not appear on the programme, and three colleagues.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1928 statistics of four counties :—

Name of county and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Somerset .. (405,250)	14·7	11·9*	0·75	1·66	1·3	2·2	45	18	4·4
Lancashire† .. (1,811,000)	14·6	11·9	0·75	1·36	2·0	1·9	69	29	6·1
Derbyshire‡ .. (624,100)	17·8	10·2	0·72	1·19	1·3	1·6	68	—	4·3
Essex .. .. (1,083,700)	16·2	10·0	0·75	1·39	1·2	1·8	51	23	4·0

* The standardised death-rate is 9·4.
† Population adjusted from 1,809,120 for changes of boundaries during the year.
‡ Population adjusted from 692,400 for changes of boundaries during the year.

Somerset.

Dr. W. G. Savage reports that the county was invaded by small-pox on four occasions and that in three instances there were single cases and in the other three persons in one family affected. The notifications of typhoid fever were higher than usual, 41 cases with 6 deaths. Twenty of them were associated with an outbreak at Weston-super-Mare, the cause of which was not elucidated. There was a welcome decline to 18 cases in the notifications of encephalitis lethargica, but the deaths ascribed to it numbered 9. Measles was more fatal than usual and caused 36 deaths, 29 being in children under 5 years of age. There are ten clinics for venereal diseases, and the figures show an increase, both in new cases and attendances. Seventy-nine per cent. of the new cases attended at county council clinics. Dr. Savage points out that the system of multiple clinics makes it possible for every case to obtain treatment at a reasonable distance from home and facilitates following up. As a result, patients attend until cure is effected much better than formerly. A table illustrates the considerable decline in the tuberculosis mortality during the last 20 years. Thus on the 1928 population 20 years ago there would be over 400 deaths annually, whereas in each of the last three years there have been under 300. The unused buildings at Quantock Sanatorium were again used as a holiday camp for 80 debilitated girls and boys with most satisfactory results. The tuberculosis officer, Dr. L. J. Short, states that the difficulties of exact diagnosis have been increased lately by the appearance of a form of influenzal broncho-pneumonia, which for a long time closely simulates tuberculosis and may go on to a fatal termination.

Infant mortality was lower than ever before, but Dr. Savage points out that 52 per cent. of the infant deaths took place during the first month, an illustration of the importance of prenatal work. The midwives attended 57 per cent. of the births and the medical practitioners 43 per cent., the exact converse of what took place 12 years ago. A table shows that although the maternal mortality-rate has shown considerable fluctuations since 1910, there has been no decided fall. There were two cases of impairment of vision among the 34 cases of ophthalmia neonatorum notified. In one case there was delay to notify; the onset was on Jan. 19th, and on Jan. 27th the case was sent to the Bristol Eye Infirmary. The other was a severe case admitted to Taunton Hospital five days after onset, but the mother refused to stay in hospital until treatment was completed. Antenatal cards are supplied to all the midwives and examinations of urine are made for them in the county laboratory. Leaflets are also supplied to expectant mothers. The scheme for searching out rickets, especially in the rural areas, continues satisfactorily. There were 241 cases brought under treatment and the figures show 14 per cent. cured, 24·6 per cent. practically cured, 42·1 per cent improved, and 19·3 per cent. with no visible improvement or needing transfer to the orthopædic clinic. The scheme has brought out the fact that other abnormalities, which may be confused with rickets, need special attention, and this extension of the scheme has been made possible by the appointment of Dr. Hilda Halliday as assistant medical officer in April, 1928. The orthopædic scheme dealt with 440 deformities, and Dr. Savage reports that a much larger percentage of the cases seek treatment in the early stages of crippling.

As regards pollution of rivers no trouble was experienced during the year from the effluents of milk depôts. There was a decline in house building, new houses numbering 1662, as compared with 2835 in the previous year. Dr. Savage points out, however, that only 750 houses are needed for increase of population and that the 1928 figure of 1662 does something to reduce house shortage and to enable unfit houses to be closed. Under the Rural Workers Act, £1987 was paid towards the renovation of 22 dwellings during 1928. In the matter of meat control the county council have had to draw the attention of the local authorities to the requirements of Section 8 of the regulations as much laxity has arisen with respect to the giving notice of times of slaughtering. In a number of the county areas no meat was condemned at all, and it is not difficult, says Dr. Savage, for diseased animals to be killed and unsound meat to be sold for human consumption. There is some improvement in the working of the Milk and Dairies Order, 1926, but in some districts this work receives very inadequate attention. During the year 40 clean milk demonstrations were given at various farms with an average attendance of 24. There were also four competitions for milkers and another clean milk competition. During the year 273 samples of mixed milk were examined biologically for tubercle, and six, or 2·2 per cent., gave a positive result. During 1926 and 1927 the percentages were 2·2 and 2·18, and Dr. Savage points out that the Somerset percentages compare very favourably with other parts of the country. In addition to the cases mentioned, two reports of tuberculous milk produced in Somerset were received, one from Bristol and the other from London. In the follow-up of these eight tuberculous milk samples—on five farms six cows with udder tuberculosis and one cow with considerable tuberculosis and yielding tuberculous milk were detected and destroyed, while on the other three farms no cow affecting the milk-supply could be traced.

Lancashire.

Dr. J. J. Butterworth's report contains much detailed information with respect to the sanitary needs, activities, and statistics of the 19 boroughs, 81 urban districts, and 19 rural districts which make up the administrative county. Water-supply is a difficult matter in some portions of the county and Dr. Butterworth hopes that the Local Government Act of 1929 may be helpful. A table of samples taken during the year shows that 2 out of 20 samples from public supplies were unsafe or doubtful, while of 34 supplies to single houses, 6 were definitely unfit and 12 of doubtful quality. A great part of the county comes under the jurisdiction of the Mersey and Irwell and Ribble joint committees as regards pollution, and Dr. Butterworth refers to the circular issued by the Ministry in March advising each county and county borough council to consider the advisability of becoming a constituent member of a joint authority for the prevention of river pollution. The new houses erected numbered 6646, to be compared with 10,170 in the previous year. The Rural Workers Act has not been much utilised as only £736 was granted in respect of eight dwellings. Thirteen joint planning committees now function in the Manchester district and five in the remainder of the county. Every urban district with a population exceeding 20,000 was required to prepare a scheme before Jan. 1st, 1929, but the date has now been extended to Jan. 1st, 1934. All the 17 boroughs, and eight of the nine urban districts in the class mentioned, have taken some action in the preparations of schemes.

The complaints of tuberculous milk produced in the county received from outside authorities numbered 329. The county veterinary surgeons in each case visited the farm and examined the cattle but it is not stated what success they had in detecting the offending cow. There are 7841 cow-keepers in the county but only 11 entered for the fifth Clean Milk Competition, and there are only five licensed to produce "Certified" milk. The county analyst, Mr. G. D. Elsdon, returned 95 out of 2771 milk samples, or 3·4 per cent., as adulterated. He further shows that the average composition of all the samples, including those adulterated and appeals to the cow, was 3·74 per cent. of fat and 8·90 per cent. of solids—not fat, and that the experience of the last nine years proves that it is rare for the milk of a herd to fall below the standard of 3·0 per cent. of fat and 8·5 per cent. of solids—not fat. Thus, out of 25,474 samples 4·4 per cent. fell below the fat standard, while 2·9 per cent. fell below the solids—not fat standard. These percentages at first sight appear to be high, but when they are checked by appeals to the cow it is fairly obvious that the majority are sophisticated. Thus, out of 461 appeals to the cow only 112 fell below the fat standard and 35 below the standard for non-fatty solids.

The notifications of encephalitis lethargica have declined steadily since the peak year of 1924, when there were 299 cases and 103 deaths. In 1928 there were 74 notifications and 76 deaths. The death-rate from pulmonary tuberculosis was the lowest ever recorded in the county. The new cases of venereal disease attending the clinics show a considerable increase on preceding years. The new cases of syphilis are about the same as in 1923 but the new cases of gonorrhœa are nearly double. More than half the confinements were attended by midwives and the percentage of stillbirths to live births reported by midwives was 2·76. The damage done by ophthalmia neonatorum was exceptionally high—viz., two cases of total blindness and five of impaired vision. The county council is the local supervising authority for the whole of the administrative county, but for child welfare its area comprises 77 districts in which 10,765 of the 26,390 births in the county were registered. Little has apparently been done in the matter of antenatal clinics. The county council has established two, at Irlam and Litherland, and has made arrangements for the use of the antenatal clinics at Widnes and Chorley, but no particulars are given as to the attendances at these clinics. In addition to this the school nurses, who also act as health visitors, paid visits to 2068 expectant mothers. The county orthopædic scheme has made progress, and provided treatment for 2308 children. Many more authorities have joined and there are now 22 out-centres in addition to the six hospitals included in the scheme.

Derbyshire.

Dr. W. M. Ash's report contains many interesting features. During the year the orthopædic scheme was further developed. Clinics were opened at Bakewell, Chinley, and Shirebrook, making nine in all. The sparsely populated western area is provided for by a motor service and occasional clinics at existing buildings or by visits of the orthopædic staff to the homes. There are 55 beds at Bretby hospital for surgical tuberculosis and eight for non-tuberculous cripples. The new 50-bed block at Bretby will be opened during the present year and the plan of an additional 32-bed block for adult surgical tuberculosis which is in the early stages of erection, is given. The crippled patients treated during the year at Bretby numbered 107; 25 cases of non-tuberculous crippling and the remainder with one or more tuberculous lesions. Of the 43 patients discharged during the year the average duration of stay was 419 days for the tuberculous and 125 for the non-tuberculous. Bretby has been approved by the Board of Education as a special school. Dr. Ash is very emphatic as to the crime of leaving young children at home with an open case of tuberculosis. The Grancher system has not found favour in this country and the alternative is the removal of the advanced case from the home. This is difficult in Derbyshire because accommodation is only provided for this type of case at Chesterfield, and it is essential that institutional accommodation for advanced cases should be so situated that friends and relatives can visit the patient with the minimum of trouble and expense. A beginning has, however, been made by the opening of a six-bedded block for advanced cases at Darley Dale.

A complete system of antenatal clinics has now been established throughout the county under the direction of an obstetrician, Dr. Edith E. Stephens. There are 12 clinics, mostly held twice a month. The inspection of the various sewage works has been made more effective by the appointment, in March, 1928, of an additional sanitary inspector. The effluent samples collected during the year were classified as follows: good 245, satisfactory 230, unsatisfactory 100, and bad 149. Two vendors were fined for the sale of sausages containing boric acid. The notifications of small-pox during the last eight years have numbered 21, 228, 476, 1123, 339, 224, 474, and 009 (with no deaths) in 1928. The County Clean Milk Competition attracted 49 entrants, 14 for the class of previous prize winners, 28 for competitors who have not won prizes, and 7 for retailers in the borough of Chesterfield. The animals slaughtered under the Tuberculosis Order numbered 517, 448 with advanced and 68 with not advanced tuberculosis, and 1 not tuberculous. Of 490 milk samples examined for tubercle 77, or 15·7 per cent., gave a positive result.

The school report shows that three new schools of the "justly famous" Derbyshire type have been completed. Most attractive illustrations are given and a descriptive note by the architect, Mr. G. H. Widdows. The schools are heated by treating the whole of the floors as radiators and they might perhaps be described as garden schools built on open-air lines. A noteworthy departure was the opening of the first of the new clinics at Alfreton, a plan of which is given. This building will be used for the combined purpose of a school clinic and an infant welfare centre, and has been erected in the grounds of the council school. The increased efficiency of the dental service is illustrated by a graph comparing conservative work with extractions. In 1925 extractions bulked much more largely than conservative work, but now the two are on a par. Mr. H. P. Sutcliffe, the senior dentist, makes an interesting communication on the treatment of irregularities of dentition under the conditions found at a school clinic, and illustrates his remarks by striking photographs of casts before and after treatment.

Essex.

Dr. W. A. Bullough says that steady progress has been made with the county tuberculosis scheme. The new sanatorium at Black Notley is nearing completion and improvements carried out at the Harold Court sanatorium have been a great asset. The increasing work of nine tuberculosis care associations has made heavy calls on their funds, which have been supplemented by the county council. Since 1921 the population has increased by about 170,000, largely owing to the rapid growth of Dagenham and other areas near the metropolis. During the last eight years 13,049 houses have been built at Dagenham and a further 1151 houses are contemplated. This rapid growth has created a need for the extension of sewerage, sewage disposal, and water-supply schemes. The advisability of concentrating sewage purification by means of valley sewers at one large efficient plant instead of having several smaller schemes has been brought forward in the case of the Roding and Ingrebourne valleys. The South Essex Waterworks Company, which had to supply a population of 244,850 in 1922, now has to supply a population of 350,000. They are obtaining additional water from the river Stour and providing a 37-mile aqueduct from Langham to Ilford. It is hoped that authorities in the "waterless" part of Essex will take advantage of the facilities provided by this aqueduct. Under the Housing (Rural Workers) Act, 1926, grants during the year amounting to £3015 have been made in respect of 35 cottages. Up to December, 1928, 60 Essex cottages had been reconditioned under this Act.

The county analyst, Dr. Bernard J. Dyer, reports that 103 out of 1604 milk samples were unsatisfactory; 44 showed evidence of added water varying from 4 per cent. to 34 per cent.; 58 were deficient in fat, varying in extent from 5 per cent. to 45 per cent., and five samples contained annatto. Instruction in the production of clean milk has been energetically prosecuted. Essex won the Stapleton Cup in the Inter-County Clean Milk Competition, held by the British Dairy Farmers Association. Routine inspection of cows by veterinary surgeons has made no progress. Of 84 samples of milk examined for tubercle 6, or 7 per cent., gave a positive result. In the follow-up of 11 "outside" complaints of tuberculous milk, four cows at four farms were dealt with under the Order; at five farms there was no evidence of disease, and at two farms the whole of the herds had been sold by public auction.

Much is hoped from the deliberations of the departmental committee which is considering the very strong report made by Mr. J. C. Dawes, Inspector of the Ministry, as to the nuisance caused by the dumping of London's refuse in Essex. Suspicion has been thrown on Brightlingsea oysters for causing typhoid fever in one case and dysentery in another. The Fishmongers Company have stopped the sale of Brightlingsea oysters in London. Mosquito control work goes on satisfactorily at Frinton-on-Sea and Walton-on-Naze. In September the medical officer of health of Chingford reported malaria in a boy of 8 years, who had stayed with his family at Walton. Investigation revealed seven cases of indigenous malaria (three of whom had suffered from malaria some years previously) in houses close to that in which the Chingford family stayed. At the back of the last-named house is an orchard and farm where *Anopheles maculipennis* has been found in both larval and adult stages. It is suggested that one or other of the patients who had formerly suffered had a relapse and infected the mosquitoes, which caused the indigenous cases.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 30TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 108 (last week 279); scarlet fever, 3311; diphtheria, 1807; enteric fever, 55; pneumonia, 1272; puerperal fever, 52; puerperal pyrexia, 100; cerebro-spinal fever, 8; acute poliomyelitis, 11; acute polio-encephalitis, 3; encephalitis lethargica, 14; continued fever, 1; dysentery, 8; ophthalmia neonatorum, 87. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Dec. 3rd–4th was as follows: Small-pox, 308 under treatment, 10 under observation (last week 310 and 8 respectively); scarlet fever, 2813; diphtheria, 2725; enteric fever, 83; measles, 425; whooping-cough, 110; puerperal fever, 32 (plus 18 babies); encephalitis lethargica, 125; poliomyelitis, 7; "other diseases," 12. At St. Margaret's Hospital there were 7 babies (plus 3 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns including London there was 1 death from small-pox, 8 (1) from enteric fever, 20 (7) from measles, 8 (2) from scarlet fever, 22 (3) from whooping-cough, 47 (10) from diphtheria, 81 (15) from diarrhœa and enteritis under two years, and 56 (11) from influenza. The figures in parentheses are those for London itself.

The death provisionally classified to small-pox was assigned to Poplar; it was, we understand, that of a premature baby. The deaths from enteric fever outside London were reported from Manchester and Gateshead. Diarrhœa accounted for 15 deaths at Liverpool, 8 at Salford, and 5 at Birmingham. Wigan reported 6 deaths from measles, Stoke-on-Trent and Manchester each 3. Bradford reported 4 deaths from whooping-cough, Liverpool 3. Liverpool also reported 6 deaths from diphtheria and Hull 4.

The number of stillbirths notified during the week was 253 (corresponding to a rate of 48 per 1000 births), including 30 in London.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Ideal Mental Hospital.

THE General Board of Control for Scotland claims to possess the ideal mental hospital at the Edinburgh District Asylum, Bangour Village. This institution lacks only one equipment, which is represented by the solarium in course of erection at Govan District Asylum. Scotland still retains the old word "asylum" which England has discarded on account of its unfortunate associations. In its original meaning of "refuge" or "a place where you cannot be robbed" no word could better denote the haven needed and often eagerly sought by those mentally disordered, but it has undoubtedly come to suggest to the uninstructed a dreary prison for maniacs where treatment is harsh and even fair play is rare. It is no doubt a matter for argument whether the best procedure is to change the name in order to disarm mistrust or so to insist on the true nature of the institutions thus called that the name loses its associations of horror. Whatever the name, there is no doubt that the modern mental home is approximating rapidly to the ordinary hospital. As the Scottish commissioners remark, "it is now more than twenty years since it was clearly demonstrated that only a negligible number of the mentally affected, whether on admission for the first time or as the result of an exacerbation of a former mental disorder, cannot be treated under the same conditions as obtain in general hospitals." Their idea of the ideal hospital includes every kind of equipment for diagnosis and treatment. If there are 500 beds or more there should, they say, be an X ray apparatus, and smaller hospitals should have access to the radiological installation of some neighbouring institution. To control the radiological department there must be a medical officer with special training and experience, and on this official will also depend the conduct of electrical therapy, hydrotherapy, and light therapy, as well as massage—therapeutic agents which are becoming general in all large mental institutions. The Edinburgh district asylum has, of course, an operating theatre, an occupational therapy department, an energetic laboratory, and an abundant supply of literature through its library. It has recently added to its visiting staff a chiropodist—a specialist who must be almost unique at present. A well-equipped dental room and a visiting dentist are, of course, essential in a good mental hospital, and consultants in each of the special branches should also be available. A constant source of anxiety to the medical superintendent is the insane carrier of dysentery and enteric Before they are detected these patients—usually women—spread the disease far and wide. Scotland has dealt with this problem by providing a special detached hospital large enough to accommodate carriers from the mental hospitals all over the country. This excellent provision is due to the wisdom of the Govan District Board of Control. The hospital has been planned on the most modern and generous lines and provides every comfort for the patients who are so unfortunate as to require segregation for this reason. Scotland was a pioneer in offering a solution of the problem of laboratory work in the smaller institutions. Nearly 20 years ago the Scottish Western Asylums joined together in the foundation of a research institute, with a central laboratory in Glasgow, to undertake the routine examinations and carry out research on behalf of a number of mental hospitals. The nineteenth annual report, just published,[1] shows that this excellent scheme is in financial difficulties but convinced of the importance of carrying on its work. The investigation of intestinal flora and the laboratory work connected with the malarial treatment of general paralysis would be almost impossible for the individual asylums, and the Institute hopes also to be able to initiate research into the problems of mental disease. An important feature of the Edinburgh institution, considered as the "ideal," is the high proportion of voluntary inmates. Nobody interested in the mental health of the nation can rest content until patients are admitted freely on a voluntary basis to every mental hospital in these islands.

A Hospital Waiting-list.

The size of the Edinburgh Royal Infirmary waiting-list has resulted in an agitation for more beds. At a meeting of the League of Subscribers, Sir David Wallace, representing the managers, made an analysis which showed that the waiting-list of 3009 (on Nov. 1st) was somewhat inflated, but with every correction the number of surgical cases requiring admission is still serious.

During the last year the infirmary dealt with 19,800 cases: 4000 medical and 14,200 surgical. The out-departments handled 67,623 cases, an increase of 6638 over the preceding year. The ordinary income was £114,896; the extra-ordinary income, £139,382; total, £254,278. This was far beyond any previous year, largely on account of legacies and donations. The ordinary expenditure was £143,684; the extra-ordinary, £18,612; total, £162,296, leaving a balance with the general fund of £91,982.

Ten years ago, said Sir David, in-patients numbered 4056 medical and 8443 surgical. The total of medical cases was still about the same, but the surgical ones had increased by 6000. The size of the waiting-list was partly due to increasing willingness to go to hospital for operation. Practically every patient now wished to go to hospital. Out of 1668 surgical cases waiting, 738 no longer required treatment, either because they could not be traced or because they had recovered. A considerable number were in special departments, thus in the present list 518 waited admission to the ear and throat department despite its enlargement three years ago. It could be stated, however, that no urgent cases, emergency or other, were refused admission. In the majority of the cases put on the waiting-list a little delay was not deleterious to the patient. But emergency cases were so numerous that waiting cases were often delayed for a "good long time."

The new Radium Institute—the first for Scotland—was to be an integral part of the infirmary; and if the contemplated plans were carried out it would mean an increase of 36 beds. The new Cripples' Hospital at Fairmilehead would also afford some relief, and pressure on voluntary hospital beds would be reduced by coöperation with the new health authorities. He was convinced that real injury, mental or physical, to the waiting patients was much less than might be supposed. The managers were doing everything they could to get patients in at an earlier period.

The meeting thanked Sir David for his address, but felt that something more practical was required from the managers, who should not underestimate the feelings that lay behind the motion. If nothing was done, the subscribers would lose confidence in an institution which they had so generously supported. It was intimated that £21,564 had been gathered from 1410 groups of League subscribers, an increase of £129 over last year. Of this sum, greater Edinburgh was responsible for £15,942; country districts for £5622.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Road Accidents and Hospital Finance.

THE hospitals of Dublin, like those of other cities, have suffered from the increasing burden of gratuitous attendance on the victims of road accidents. This is an aspect of the results of modern road traffic which should not be overlooked in the discussion of compulsory insurance against third-party risks. Mr. A. B. Clery, assistant surgeon to the House of Industry Hospitals, Dublin, discussed the subject in an interesting address delivered last week to the Dublin Rotary Club. He pointed out that the treatment given by the hospitals diminished the liability of those responsible for the accident, and it was unjust that the hospitals should be expected to do this work for nothing. The loss incurred in this way had to be made good from moneys intended for the relief of the sick poor. Even if the injured party were awarded damages to cover hospital expenses, the money did not always reach the hospital. Mr. Clery stated that in our hospitals in Dublin 42 interne cases of road accident had been treated since Jan. 1st, involving an expense of £465, while the receipts on account of these cases was only £82. He estimated that the Dublin hospitals lost annually between £3800 and £4000 by their care of cases of road accident treated in the hospitals, without taking account of the large number treated in the externe departments. As the number of road accidents was increasing enormously the problem of safeguarding funds intended for the relief of the sick poor was becoming more urgent. Speaking on a vote of thanks to Mr. Clery, Mr. Henry Stokes, surgeon to the Meath Hospital, said that the care of the victims of a single 'bus accident which occurred last summer had already cost his hospital £300, for which they would not receive a penny.

An Electrotherapeutic Clinic in Dublin.

The Joint Committee in Ireland of the British Red Cross and the Order of St. John of Jerusalem established in Dublin an electrotherapeutic clinic for ex-Service men. There is no longer a need for it for this class, and the committee has now decided to open it for the use of patients of small means. A circular letter has been issued to the medical profession of Dublin inviting them to make use of the clinic in suitable cases. No patient will be received unless recommended by his own medical attendant, and medical men are requested only to send patients who are unable to pay the usual private fees. The clinic is in charge of a certificated nurse, experienced in such work, and it is equipped to provide massage, remedial exercises, electric treatment, radiant heat, ultra-violet light, and diathermy. It has a useful function to perform.

Mass Effect of Goitre.

At a meeting of the Ulster Medical Society on Nov. 28th Mr. Howard Stevenson, the President, introduced Dr. A. Murray Drennan, the newly appointed professor of pathology in the Queen's University of Belfast, who read a paper on Some Aspects of Goitre: the Mass Effect. Prof. Drennan based his remarks on work done by himself and his former colleagues at the University of Otago, New

Zealand, in which observations of the histological appearances of the thyroid gland in health and disease were correlated with the clinical history, with the gross bulk of the gland, and with estimations of its iodine content. He demonstrated by diagrams and a large number of lantern slides of microscopical sections the various histological appearances of the gland, and observed that the changes considered to be characteristic of the different types of goitre could be found in the post-mortem room in glands of normal size, where there was no history of symptoms. He then proceeded to show the effect of diminished iodine intake, which led to increase in size, but to a lower pressure of iodine, succeeded, if iodine were administered, by a colloid toxic goitre, provided the mass of gland were sufficient. If the gland was in a diffuse secretory stage with increase of its smaller vesicles, the typical appearances of exophthalmic goitre might arise; in this case administration of iodine enabled the gland to revert to a storage state. He emphasised the complexities of the thyroid problem, amongst these being the extraordinary number of secondary changes, such as hæmorrhage, fibrosis, and atrophy which complicated the clinical findings.

In the discussion which followed, Dr. Olsen said that as a co-worker of Marine in America he had followed the work of the Otago school with interest. He expressed the view that the different forms of goitre were not so sharply separated as had been thought; he was of the opinion, however, that true exophthalmic goitre should not be treated surgically, while obvious adenomata should be operated on.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Vasoligature Deemed Assault.

A WEEK or two ago there was a very remarkable trial in Graz, the second university city of Austria. A surgeon of good reputation was accused of causing bodily harm to a large number of men by performing on them an operation which, as the court believed, had the effect of sterilising them permanently. It appeared that a prisoner, when examined before starting a term of hard labour, showed on his scrotum scars from an operation which he explained he had had done with the object of becoming sterile. In his native town, he said, a large number of men had applied to a surgeon named Schmerz for the same purpose, and had obtained the desired result. In the course of the proceedings it was stated that more than 700 men had been operated upon by Dr. Schmerz in the last two years. The court regarded this wholesale sterilisation as a danger to public welfare, and although the accused said that his operation was only a temporary sterilisation and could (so to speak) be undone at any time, and that he always took care to operate only in cases where definite social or medical indications were present, he was found guilty of gross offence. In vain the witnesses and medical experts whom he called gave their evidence for him. In vain it was asserted that the method was perfectly free from any danger in the hands of this excellent surgeon, and that in view of the frequency and danger of abortion vasoligature was desirable where prevention of issue was necessary. Despite these pleas the learned judge found the doctor guilty, and as he could not deal with the offence under any other heading, he turned to an old law of 1858 which applies to injuries inflicted by assault or attack, and sentenced the accused to a fine of 15,000 Austrian shillings (about £150) or two weeks' imprisonment. Naturally this sentence will not be left without appeal. Public opinion has been seriously disturbed, and comments, both professional and lay, are not very complimentary to this way of administering law. It must be added that a certain number of medical men disapprove of Dr. Schmerz's procedure, and hold that the judge's opinion was correct. At any rate, the case will be brought once more before a jury, for otherwise every surgical interference might be regarded in the same light, and every surgeon would run the risk of heavy fines for fulfilling his professional duties.

The Gerson Diet in Tuberculosis.

The treatment of tuberculosis by means of a diet free from common salt continues to be in the foreground of medical discussion. This new treatment, as applied first by Dr. Gerson and later by Prof. Sauerbruch on a large scale,[1] has given excellent results in their hands, but has also been attacked from several quarters. Accordingly a group of eminent Viennese professors was sent to Sauerbruch's clinic at Berlin to investigate the actual conditions of treatment. The commission consisted of Dr. Durig, a physiologist; Dr. Eiselsberg, a well-known surgeon; Dr. W. Neumann and Dr. Löwenstein, specialists in tuberculosis; Dr. Volk, well known for his researches on skin diseases; and Dr. Walzel, also a special surgeon. These men had every opportunity of studying the work in Berlin, and could compare the state of patients before and after treatment by the new diet. Clinical and photographic records were examined, and the commission got a distinct impression that at least in surgical and dermatological cases the diet led to marked improvement. A sine qua non is strict and conscientious adherence to the absolutely salt-free diet—a very trying task both for the patients and the medical and nursing staff. It is not unlikely that some of the bad results obtained at several other centres have been due to neglect of this point. The investigators on their return to Vienna strongly recommended that the method should be tried here, and on this recommendation the Red Cross of Austria has volunteered to place at the disposal of the University of Vienna its tuberculosis sanatorium at Grimmensteinn, 60 miles away, where there is every opportunity for enforcing the necessary diet. Furthermore, at another place much nearer Vienna the same experimental observations will be started. The chief drawback of this useful method is the craving for salt, which soon sets in and somewhat torments the patients. A suitable change in the otherwise fairly uniform diet is therefore of the utmost importance. It may be added here that since Dr. Gerson's first publication of his diet, Dr. Max Jerusalem, a surgeon of the workmen's sickness insurance club, has treated quite a number of patients on these lines, and is satisfied that they represent a real advance in the therapy of tuberculosis of the bones and the joints.

Cutaneous Immunisation.

In view of the difficulty of getting parents to consent to injection of toxin-antitoxin for prevention of diphtheria, Prof. Löwenstein has tried combining the two substances in an ointment which is rubbed into the skin. After prolonged trials by Dr. Poindecker in a children's hospital, the ointment was found to give excellent results in 68 to 70 per cent. of cases, and accordingly it will now be used in all the municipal kindergartens. The parents will be handed a pamphlet with complete explanations, and it is expected that no difficulty will be experienced. The health authorities hope soon to eradicate by these means this dangerous disease at least amongst the youngest children. The ointment is rubbed in over the sternum in intervals of 8 to 14 days.

During the summer term of 1929 the number of medical students who proceeded to the M.D. degree was 126. Of these 63, or exactly half, were of foreign nationality, and it is clear that this high percentage of foreign students is of utmost importance to our University.

Dr. J. Rosmanit, who died recently, was a surgeon and physician of the old type, and though his work was never in the limelight it was none the less important. He was the inventor of the widely used railway first-aid apparatus, and served as the chief staff doctor of the Austrian State railways. During the war he contributed many useful suggestions concerning the methods of transport of the wounded and sick.

"Audi alteram partem."

THE MEDICAL AND DENTAL REGISTERS.

To the Editor of THE LANCET.

SIR,—In order to facilitate the work of those who find it essential to know whether a practitioner is legally qualified or not—such, for instance, as officials of insurance committees, chemists and druggists—the Council are continuing to publish an office edition of the Medical Register. This edition is bound in paper boards and contains all names and addresses as they appear in the official edition but is printed on cheaper paper and without the preliminary matter. The office edition is published at the special rate of 7*s.* 6*d.* post free, but no copies can be issued at this price unless they are ordered and paid for prior to Dec. 31st of the year preceding that of publication. Order forms will be sent on request. The Council also issue each month lists of new registrations and names deleted from the Register. These are issued on a written understanding that the lists are for the personal use of the firm to which they are supplied, that they are not communicated to any other person, and that they are not sent out from the office in order to have stencils made. Every possible care is taken to protect subscribers from the lists being made use of by others. I might add that these lists are for obvious reasons not supplied to any addressing agency; the Council has no business arrangement or agreement of any kind with any addressing agency for supplying to them any official information and it certainly has no exclusive arrangement of this kind.

Similarly the Dental Board of the United Kingdom issue an office edition of the Dentists Register which includes the names of all registered dentists together with a local list. The price of this is 4*s.* post free, provided copies are ordered and paid for prior to Dec. 31st of the year preceding that of publication. Monthly lists of new registrations and deletions are also issued by the Board. I might add that the General Medical Council and the Dental Board are always glad to answer inquiries as to whether practitioners are registered or not. Preferably these should be in writing to prevent misunderstanding but inquiries by telephone are replied to at once.

I am, Sir, yours faithfully,
NORMAN C. KING,
Registrar.

General Council of Medical Education and Registration
of the United Kingdom, 44, Hallam-street,
London, W. 1, Dec. 4th, 1929.

THE CRAFT OF SURGERY.

To the Editor of THE LANCET.

SIR,—Prof. Tonks touches upon a subject which I have repeatedly emphasised in discussions on hospital training. He very rightly points out that the dental branch of surgery is the only one in which any attempt is made to instil craftsmanship in the student, and that this teaching is of great value is well demonstrated in those hospitals where there are combined medical and dental schools. It is common knowledge in such hospitals that when dental surgeons pass into the wards to complete their medical training they usually make good dressers, and not infrequently upon completion of their training secure surgical appointments. That the value of craftsmanship is not sufficiently appreciated by the examining bodies is shown by the recent dental curriculum of the London University degree in dental surgery, where the standard of prosthetic dentistry is lower than that of the L.D.S., whereas the standard of the more academic subjects is considerably higher.

This gradual tendency to exclude the teaching of craft in favour of more theoretical subjects is certainly distressing, and in my opinion a course of craftsmanship should be made compulsory with students intending to take a higher course in surgery. As Prof. Tonks emphasises, the capable surgeon is usually made, not born, and unless an apprenticeship is served in the use of the hands and tools one cannot expect students to attain that dexterity and skill in operating which is so necessary and vital to their success. It is sometimes almost a painful sight to watch a young surgeon using a saw or chisel, being obviously unfamiliar with the tool, and there is no doubt that a little more teaching of the fundamental use of instruments would increase his confidence and skill, to the great help of both himself and his patient.

I am, Sir, yours faithfully,
W. KELSEY FRY, M.R.C.S., L.D.S.

St. Thomas's-street, S.E., Dec. 4th, 1929.

THE POSITION OF PUBLIC VACCINATORS.

To the Editor of THE LANCET.

SIR,—On behalf of the Councils of the Poor-law Medical Officers' Association, and the Public Vaccinators' Association, I am desired to appeal, through your columns, to all public vaccinators and Poor-law medical officers, who are also members of the local authority to which they will be transferred on April 1st next, to communicate with me at once, if they have not already done so, giving such particulars as may be useful in framing representations to the central authority on their behalf.

I am, Sir, yours faithfully,
ALBERT ERNEST COPE, M.D.,
President of the Public Vaccinators' Association;
Secretary of the Poor-law Medical Officers' Association.

Belgrave-road, Westminster, S.W., Dec. 7th, 1929.

CLINICS FOR RHEUMATIC CHILDREN.

To the Editor of THE LANCET.

SIR,—Dr. Burnet's plea for the establishment of special clinics for the supervision of rheumatic children needs no endorsement from me, but I may perhaps be allowed to say that his ideals are by no means as "premature" as he seems to think. There are already about a dozen such clinics at work in the London area, and many more scattered in the big cities of England and Scotland, and at least one in Ireland. I do not attempt to enumerate them lest I should leave out some unknown to me. Only last month did I hear of a new one to be opened shortly at Hull; and so the good work spreads. In many instances these clinics have adopted the plan which I think is best—namely, they are attached to a children's hospital, using its personnel and premises, and having ready access to every in- and out-patient department.

I concur with Dr. Burnet that these clinics should incorporate the word "rheumatism" in their title, and regard this as of great importance to the preventive aspect of the work. In London many of the clinics are called "rheumatism supervisory centres."

I have sometimes been betrayed into passing criticisms on the school medical service, but this rôle I see I can advantageously leave to Dr. Burnet. Perhaps, were its work boomed a little less vigorously, he would see that it does not cover the ground he expects of it. Official inspections at very long intervals are not going to do the work of careful and frequent examinations, and they are quite insufficient to pick out all early cases of rheumatism. There is, I am told, a schedule of disorders on which the school medical officer works, to the detriment of the child who has not the civic sense to ail *à la carte*, and I doubt if we are right in expecting him to come to real grips with the intricacies of clinical medicine. But I cannot in fairness close without testifying to the great value of the special schools for physically defective children, where many heart cases do phenomenally well. For myself I would say that the best régime in the long run for rheumatic children with heart disease is to live at home, attend a school for physical defectives, and be periodically examined at a centre at a children's hospital.

I am, Sir, yours faithfully,
REGINALD MILLER, M.D., F.R.C.P.
Harley-street, W., Dec. 7th, 1929.

To the Editor of THE LANCET.

SIR,—As a comment on Dr. Burnet's letter, I may perhaps be allowed to furnish a short account of our experience in Bristol. It is about six years since our colleagues in the school medical service began to refer to Dr. C. E. K. Herapath and myself selected cases of doubtful or early cardiac disease discovered in the course of their routine medical inspections. These children we saw in our out-patient rooms and then reported as to their fitness to attend school, need for treatment, and so on. Between two and three years ago this plan was stabilised and extended by agreement between the various local authorities concerned on the one hand and certain hospital physicians on the other—a step which was promoted by the Cardiac Subcommittee of the Science Committee of the British Medical Association and assisted by the Medical Research Council—and since that time it has operated smoothly over an area of three counties.

We trust that this work will afford a basis of data broad enough for conclusions as to means of prevention of rheumatic carditis, while at the same time we are convinced that good is already being done in bringing these children under medical care earlier, and over longer periods, than formerly. We think, moreover, that we have gained valuable experience in harmonious coöperation with our colleagues—those of the whole-time services on the one hand, and the family practitioners on the other. It would be foolish to pretend that no difficulties have arisen, but so far it has proved possible, by relying on the goodwill of everyone concerned, to overcome all these.

Valuable work of the same kind is also being done in London, Birmingham, Glasgow, and elsewhere. Those who are interested in tracing the progress of the whole movement will find some account of it in recent annual reports by the chief medical officer to the Board of Education.

I am, Sir, yours faithfully,
CAREY F. COOMBS.
University Centre of Cardiac Research, General Hospital,
Bristol, Dec. 9th, 1929.

THE ACUTE VULVITIS OF LITTLE GIRLS.

IS IT GONORRHŒAL?

To the Editor of THE LANCET.

SIR,—In the contribution by Dr. H. C. Cameron in your issue of Nov. 23rd (p. 1115) several questions are raised which I feel require an answer. Dr. Cameron suggests that acute vulvitis in children may not be caused by the diplococcus found in adult infections. The following analysis, in my view, strongly supports the general belief that the organism in the two conditions is identical.

Among 47 consecutive cases of gonococcal vulvo-vaginitis in children (bacteriologically confirmed) treated at the V.D. clinic of Guy's Hospital, the infection in 20 cases (42·5 per cent.) was found to be present in one or other parent, although in some of the cases the parents denied symptoms. In one case, transferred from a ward where there was an epidemic of vulvo-vaginitis, no evidence of infection could be found in the parents. In 26 cases (54·5 per cent.) the examination of parents was either impossible or bacteriological reports were inconclusive, although clinical examination revealed extremely suspicious evidence. Among these 26 cases four were associated with the epidemic already mentioned.

Whilst presenting these figures I do not for a moment deny the well-known fact that organisms other than the gonococcus—for example, *B. coli*, the streptococcus, *Micrococcus catarrhalis*, &c.—are frequently the cause of vaginal discharge in children and adults. Such cases after thorough investigation are discharged from the V.D. clinic as not venereal.

Dr. Cameron suggests that the epidemic is kept up by the anxiety of those concerned in combating it and dies down only when their activities cease from exhaustion. I maintain that it is arrested by the isolation and treatment of affected cases and the strict enforcement of rules. Since improved preventive regulations have been carried out there has been no spread of gonococcal vulvo-vaginitis in the wards of Guy's Hospital.

The assumption that only local treatment is given by medical officers in charge of V.D. clinics is not justified. The general condition of children suffering from gonococcal vulvo-vaginitis is not ignored in these clinics and measures designed to promote the general health are taken. In these cases the children generally show marked improvement in general condition and when judiciously handled do not show signs of nervous upset.

At the Children's Home, Waddon, where there are 37 beds for venereal disease, marked improvement in general health and gain in weight is the general rule, although local treatment is carried out daily in almost every case. Many cases of apparent recovery, under general and local treatment, are still found to be positive to bacteriological tests, sometimes months after all symptoms have disappeared. Also contacts with no symptoms are frequently found to be infected. These cases I consider to be carriers, comparable to those apparently well after general treatment only. It would be important to know the incidence of untraced infections due to this type of case. As to the question of ophthalmia, does Dr. Cameron consider it a common occurrence in adults? I confess to have seen a case in adult or child only very rarely, excluding, of course, ophthalmia neonatorum.

I consider that gonococcal infection in children is not the trivial condition which Dr. Cameron appears to imply, and that general treatment only is insufficient to effect a cure.

I am, Sir, yours faithfully,
MORNA RAWLINS.
Devonshire-place, W., Dec. 5th, 1929.

SUGAR IN ASTHMA.

To the Editor of THE LANCET.

SIR,—In his interesting article last week (p. 1187) on Asthma in Children Dr. A. A. Osman says that as far as his experience goes "sugar is without value in the treatment of asthma in adults." May I say that only last summer a gentleman, aged 70, whom I have known many years told me that he was recently cured of asthma by eating honey for a short time, especially from the lime tree.

I am, Sir, yours faithfully,
R. HENSLOWE WELLINGTON.
London, Dec. 9th, 1929.

SHEFFIELD HOSPITALS.—According to the 131st annual report of Sheffield Royal Infirmary 6810 in-patients were treated to a conclusion, an increase of 678; they cost £3 4*s*. 1*d*. per week. The pressure upon the out-patient department may be gauged by the fact that 27,856 persons were treated in the casualty department section. A new block is being provided which will contain casualty, massage, dermatological, and dental departments, an accident theatre, pathological, physiological, and biochemical laboratories. Last year marked the completion of 60 years' work of the Jessop Hospital for Women. The average stay of maternity patients was a small fraction in excess of 12 days; the puerperal sepsis patients, on the other hand, remained for an average of 23 days. In the absence of the money needed to provide research laboratories, especially for puerperal sepsis, it was hoped to convert some existing rooms for this purpose.

Obituary.

PHILIP HEDGELAND ROSS.

THE many friends of the late Dr. P. H. Ross who have heard with regret of his passing, will agree with the writer, who knew him nigh on 30 years, that the brief notices of his death announced in the newspapers in England, East Africa, and possibly in New Zealand cannot be deemed sufficient. The good work done by Ross, notably during the years he was in East Africa, whence the writer has but recently returned, deserves to be chronicled.

Ross was born in Christchurch, New Zealand, on July 4th, 1876. He was educated at Christchurch, Otago University, and at St. Bartholomew's Hospital, London. He became qualified in England M.R.C.S. Eng. and L.R.C.P. Lond., 1900; D.P.H. Cambridge, 1902. He held the Certificate of the London School of Tropical Medicine and won the Cragg's Research Prize, 1905. He gained the distinction of being elected Foreign Corresponding Member of the Société de Pathologie Exotique, Paris.

His research work dealt with the transmission of trypanosomiasis by various species of *Glossina* and of African relapsing fever by *Ornithodorus moubata*. Ross and Milne were the first to record human spirochætosis in Uganda. Ross was the first to discover the occurrence of piroplasmosis in monkeys (*Cercopithecus*), he described the parasites accurately, but did not figure them, he gave temperature charts, &c., of the infected monkeys which came from the Kikuyu District, Kenya. [Nuttall (Parasitology, 1908, i., 130), who studied Ross's preparations, gives the name of the species as *Piroplasma pitheci*, P. H. Ross, 1905, finding that its development in the peripheral blood (illustrated) is similar to that of *P. canis*, *P. bovis*, &c.]

His official work related less to research than to practical issues. In 1903 he was appointed to the East African Medical Service, and soon after became Government Bacteriologist to the East Africa and Uganda Protectorates, doing highly efficient work at Nairobi which led to his being made the first Director of Laboratories in East Africa. During the outbreak of plague in Nairobi in 1905 his services were so highly appreciated that he received the personal thanks of the Secretary of State. In March, 1916, he became Honorary Adviser to the Director of Medical Services in East Africa and undertook all the laboratory work for the Military Hospitals in Nairobi. Here he did great service in combating bacterial dysentery, being assisted by Dr. Kauntze; the death-rate due to this disease had been 40 per cent. After much work he prepared a carbolised polyvalent vaccine (from untreated cultures) which caused the death-rate to fall quickly to less than 5 per cent.

He wrote on June 25th, 1917, to his late mother: "We started trying it on Sept. 1st, and the first three months' results were so good that Kauntze suggested trying to inoculate the healthy carriers (of Carrier Corps) to stop them getting dysentery. It meant a fearsome amount of work, as Pillay [his Indian assistant] and I were then alone, and had seven hospitals to work (about a thousand examinations a month) and vaccine lymph to prepare and issue at the rate of 1,800,000 doses per year. But I just managed to keep the carriers supplied, though it was a very close thing. I had cabled the Crown Agents for material essential for making of culture broths, and there was delay in getting it. I borrowed from the vets., got the D.M.G. to send me material from German East Africa, and the Governor to borrow all that the Uganda Government possessed, and was down to the last bottle when a parcel-post arrived with 20 pounds worth. So now I am turning the stuff out by the bucketful and have at last persuaded the medical authorities at Dar-es-Salaam to give it a trial in their hospitals. . . . It [the vaccine] is certainly a good thing for treatment, and I hope will prove equally effective as a prophylactic. When I can get figures from the military they will prove or disprove its utility. I got the doctor of the King's African Rifles to do 7000 inoculations in a camp where they were badly troubled with dysentery, and he had only three cases afterwards, of whom one was found to have escaped inoculation."

Owing to failing health he was invalided out of the East African Service, and in April, 1919, with his wife and son returned to Christchurch, N.Z. He came again to England in June, 1926. He died unexpectedly of pancreatitis on August 6th, 1929, at Sherborne, after but a day's illness. He left a widow and one son, now a student at Corpus Christi College, Cambridge.

The following is a list of Ross's published papers:—

Ross, P. H., and Milne, A. D.: Tick Fever, Brit. Med. Jour., 1904, ii., 1453. Ross: A Note on the Natural Occurrence of Piroplasmosis in the Monkey, Jour. Hygiene, 1905, v., 18–23. Ross and Hodges, A. D. P.: Notes on a Case of Spirillum Fever in Uganda, Brit Med. Jour., 1905, i., 713–15. Ross: Tick Fever, Jour. Trop. Med., 1906, i., 65–69. Report on Experiments to Ascertain the Ability of Tsetse-flies to Convey *Trypanosoma gambiense*, &c., Roy. Soc. Rep. Sleeping Sickness Commission, 1907, viii., 80–85. Article Tick Fever in Allbutt's System of Medicine, 1907, ii., pt. 2., pp. 301–306. Some Experiments with Vaccine prepared according to the Method of Achalme and Marie Phisalix, Bull. Soc. Pathol. Exot., 1911, iv., 283–86. Spirillosis, Nairobi Laboratory Reports, 1911, pp. 6–12. Human Spirochætosis; syn. African Relapsing Fever, Human Tick Fever, Transvaal Med. Jour., 1911–12, vii., 125–29. Poisonous Insects of South Africa, New Zealand Med. Jour., 1912–13, xi., 176–91. A Further Experiment with Vaccine, prepared according to the Method of Achalme-Phisalix, Bull. Soc. Path. Exot., 1913, vi., 144. Ross and Shircore, J. O., Epidemic Cerebro-spinal Meningitis in Nairobi, British East Africa, Trans. Soc. Trop. Med. and Hyg., 1913–14, vii., 83–95. Ross, Gózony, L., and Hindle, E.: Serological Tests. I. On the Persistence of Precipitins in Sera Stored in Vitro. II. On the Reaction obtained with (*a*) Complement-fixation Tests, and (*b*) Precipitin Tests, with the Gut Contents of Blood-sucking Arthropods, Jour. Hygiene, 1914, xiv., 354–59. Ross: Dermatitis due to the Secretion of a Beetle in British East Africa, Jour. Trop. Med. and Hyg., 1916, xix., 202. Ross and Kauntze, W. H.: The Use of Polyvalent Vaccine in Dysentery, THE LANCET, 1917, i., 905. Ross: Some Observations on Malaria and Helminthiasis in Central Kavirondo Reserve adjoining Kisumu, Kenya and East Africa Med. Jour., 1929, v. 367–74.

The published work affords but slight evidence of Ross's industry and efficiency, since most of his time in Africa was occupied in the routine work of preparing vaccines for plague and dysentery on an extensive scale in connexion with epidemics and in dealing with numerous practical problems.

All who knew Philip Ross will recall his genial personality, his never-failing interest in helping others over difficulties, and the devotion he showed to the work in his domain. In East Africa he gave devoted service to mankind.

G. H. F. N.

JOHN SCOTT RIDDELL, M.V.O., O.B.E., M.B., LL.D. ABERD.

MR. Scott Riddell, who died on Dec. 5th at the age of 65, was one of the best-known surgeons of his generation in the north of Scotland. Some years ago he retired from active practice, but his time was very much occupied by public duties. He was General Council Assessor on the Aberdeen University Court, University representative on the City of Aberdeen Territorial Association, and chairman of the Joint (Disablement) Committee of the North of Scotland under the Ministry of Pensions. He also served for some years as chairman of the Managers of the Royal Infirmary. He had the temperament that made these duties a pleasure and, when a man was needed for such a position, his name always sprang to the lips. In his latter years he had to fight against a chronic disablement, but this never affected the liveliness of his interest, the readiness of his activity in public causes, or the quality of his advice in council.

In the real sense a man of action, Riddell's capacity for action was broadly based in sound scholarship both general and professional. After a long apprenticeship in classics he graduated in medicine in 1888, and soon showed a strong disposition to surgery. For seven years he acted as assistant professor of surgery when Sir Alexander Ogston was the professor. To those that began their surgery under Ogston the thoroughness of the discipline implied by those seven years needs no comment, and Riddell profited to the full by the association. He became not merely a good teacher but a skilled diagnostician and operator. He passed on to the staff of the Royal Infirmary and, in due course, became one of the consultant surgeons. His enthusiasm and lucidity in exposition made him a first-class clinical teacher and he developed a very large operative practice. He was a breezy, active, eloquent man and whatever he took up was sure to succeed. He was ready to argue and discuss with forcefulness, but always in good temper. In a word, he was a general favourite wherever he went and the professional men knew that his work was reliable. In his early days, and for many years, he conducted classes in ambulance work. His Manual of Ambulance ran into many editions and became a standard text-book in the North-East. He had the qualities of a leader and took his full share in work outside the profession. He was a member of the Council of the British Red Cross Society (Scottish Branch). He was Red Cross Commissioner for the North-Eastern District of Scotland. He became Major and Commanding Officer of the R.A.M.C. (Volunteers) and later Lieutenant-Colonel. He was Colonel and administrative medical officer of the Highland Division, Territorial Force, from 1908 to 1912. In these posts he was full of energy and stimulus and knew no fatigue. He took a full part in the appropriate surgical work incidental to the war and was made O.B.E.

A colleague writes: "Riddell was a fighter and could take a very strong stand on matters of professional administration. When the movement for the coördination of hospitals began in Aberdeen he nailed his colours to the 'voluntary' mast and showed all the good qualities of a 'die-hard.' In the end he changed his point of view and fell in cordially with the new developments. It was always a pleasure to discuss affairs with him even when he was on the opposite side. There was no sullenness of antagonism and no unreadiness to admit the justice of another standpoint. It was a pleasure to walk and talk with him and to hear his full-blooded and rapid opinions de omnibus rebus; but not least on surgery, which began with him as a passion and so remained. Like his great master, Ogston, he filled his students with enthusiasm, and each of them will with a full heart place a stone on his cairn. He was a native of Aberdeen and an out-and-out Aberdonian, but he had a bright way with him and the absolute self-confidence that marks the good surgeon and the military leader."

Mr. Riddell did a great deal to maintain the high standard of teaching both in the University and in the Royal Infirmary. His long and varied experience gave great weight to his opinions and his eloquent way both in speech and in writing secured a ready audience all over the North-East. The new Medical School and the new Royal Infirmary of Aberdeen owe, indirectly, not a little to Riddell's forceful personality.

THOMAS FINLAYSON DEWAR, C.B., M.D. ABERD., D.Sc. EDIN.

Dr. T. F. Dewar's death on Nov. 27th removes a man of exceptional attainments. A native of Arbroath, in Angus, he graduated before he was old enough to register, and then joined in his father's practice for some 12 years. The Dewar family of practitioners—father and two sons—was very well known in the East of Scotland. To his medical degrees he added the D.Sc. in public health, and when the medical officership of Angus fell vacant he was appointed to fill it. A little later he succeeded Dr. Nasmyth as county medical officer of Fife and Kinross, and it was his work in Fife that first attracted attention to his high quality. He had an instinctive capacity for organisation and administrative work. He kept the public health and the school medical service at a high level and, when in 1910 a second medical inspector was wanted for the Local Government Board of Scotland, Dewar was offered the appointment and accepted it. From that time till his death he was a member of the Civil Service. In this post as an officer of the medical staff he showed the same eager exactness in his work and the same unsleeping devotion to duty. He soon came to know the whole staff personally, and he became their natural consultant in medicine and other affairs.

From early manhood he was an active member of the Fifeshire Yeomanry, and in the South African War he became Surgeon-Captain in the Imperial Yeomanry, receiving the Queen's medal with four clasps. He published a volume "With the Scottish Yeomanry, 1901," and as a result of his South African experience he also produced a volume on "Sanitation of Armies in the Field." When the late war broke out he became an officer in the Territorials and was called up with the First Army. In 1915, he was D.A.D.M.S. of the 51st Division, and from April, 1916, to January, 1917, he was A.D.M.S. of the Northern Army, being mentioned in dispatches four times. He received the C.B. (Military Division) in 1918. For a period he had charge of the troops at Bedford, and his report on the outbreak of measles among the Highland regiments was an excellent piece of work.

When Dewar in 1918 returned to his civil work at the Local Government Board he was placed in charge of the venereal diseases section and the medical work of the poor-law; but his all-round ability led to his being entrusted with many difficult special inquiries. When the Board was superseded by the Scottish Board of Health, Dewar continued on the same general lines of work, but his time was devoted largely to nursing and developing the venereal disease clinics. A member of Lord Salvesen's Committee on maternal mortality, he made this subject also very intimately his own, but for the last few years he had specialised in venereal diseases and the medical service under the poor-law. His special chapter on venereal diseases in one of the annual reports of the Scottish Board of Health was afterwards published as a separate pamphlet and was an exceptionally useful piece of work.

A colleague writes thus of Dr. Dewar's methods: "Whenever he took up a new subject he went straight to the best authorities; he spent time in the laboratories mastering the technique involved and, when consulted, he could be relied upon to give with precision the essence of the latest work. Many years ago he deliberately elaborated a method of recording and filing both information and reports, and unlike most people he not only created the system but kept rigidly to it even at the expense of his health and strength. His system became an objective code of duty, and it is hardly too much to say that every half hour of his day was noted in his diary for three months in advance and the programme was rigidly adhered to. . . . A man of chivalrous nature, he was highly strung, keenly sensitive to every social influence, alert and full of a witty humour, and his graciousness was a proverb with those that knew him intimately. One of his juniors rightly called him 'one of the aristocrats of the profession,' and while he was conscious of his value and his power, he was the most modest of men."

Dr. Dewar was 63 years of age. He was an accomplished writer, and his long series of Medical Vignettes to the *Caledonian Medical Journal* contain some admirable descriptions of war in the field.

JAMES GILLON ROSS, M.B. EDIN.

Dr. J. G. Ross, who died at Whitby on Nov. 20th, was the son of the late Mr. Gilbert Grange Ross of Thurso and was born in Calcutta 50 years ago. He received his early education in Switzerland and Germany, and later at University College School, London, where he distinguished himself as a cricketer. At Edinburgh University he became secretary of the Athletic Club and was notably successful in various forms of sport, especially running and swimming. The Queen's Edinburgh Rifles found in him a keen member, and after graduating as M.B. in 1897 he joined the Volunteer Medical Staff Corps. On leaving Edinburgh he became house surgeon at the Nottingham General Dispensary, and served for two years in Northern Nigeria in the West African Frontier Force. In 1902 he went to Whitby as assistant to the late Dr. John Wilson, and shortly afterwards entered into partnership, which he subsequently shared with the late Dr. W. H. Wilson, Dr. John Wilson's son. When the partnership was dissolved he remained in Whitby, and carried on the practice on his own account for about twenty-three years. At the time of his death he was medical officer of health for the Whitby urban district council, and had the child welfare centre under his care. A man of wide interests, he was always eager to learn of the latest methods for combating disease, and he did excellent work as instructor in ambulance work and first aid. A prominent Freemason and this year's president of the Whitby Rotary Club he was held in high esteem by his fellow townsmen. Dr. Ross saw service in the late war first with a Yorkshire Battalion and later on the staff of the Tigue Hospital at Malta. He married in 1902 Elizabeth, daughter of the Rev. George Dodds, and she survives him with a daughter and two sons, one of whom is a medical student at Leeds. His brother is Dr. Donald Ross of Lochgilphead.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS.

THE FIRST GENERAL MEETING.

THE first general meeting of the Fellows and Members of the British College of Obstetricians and Gynæcologists was held in London on Dec. 3rd and was largely attended. The President, Prof. W. Blair Bell, was in the chair, and in proposing the adoption of the report of council and the balance sheet, pointed out that the College was only incorporated as lately as Sept. 13th last. Consequently the report was brief, and the balance sheet represented for the most part the financial arrangements prior to incorporation. While registration receipts for fellowship and membership and the annual subscriptions might be sufficient to keep the College going as at present conducted, they would be quite inadequate to liquidate the expenses of a College building, or to provide the funds from which a suitable home could be purchased and furnished. The treasurer hoped, therefore, to establish three funds—an endowment fund (not less than £100,000), a house and furnishing fund (£30,000), and a fund to wipe out the liabilities in connexion with the incorporation and pre-incorporation expenses (£1600). Lord Riddell had generously given £1000 for general purposes, and other sums and benefactions had been promised. The President gave a brief sketch of the constitution of the College and of its aims. Incorporation, without the use of the appendage "Limited," was the present legal status of the College, and this gave certain financial advantages in regard to trusts and other matters. The present state was to be regarded as a stage only in progress towards the dignity of a Royal Charter, for the attainment of which the College must prove its worth to the State.

It was proposed to elect as Foundation Fellows of the College practically all of the senior obstetricians and gynæcologists in England, Scotland, Wales, Ireland, and the British Dominions; and as Foundation Members, who would subsequently become eligible for the Fellowship, the less senior obstetricians and gynæcologists. Already a majority of those approached in Great Britain and Ireland had joined; those resident in the British Dominions had not yet been invited. It was intended to elect as fellows and members only those engaged exclusively in obstetrics and gynæcology, though a certain latitude would be allowed, for example, in regard to those engaged in the public health service. The College hoped to discuss with the Royal College of Physicians of London and the Royal College of Surgeons of England the details of the granting of a diploma in obstetrics and gynæcology, for the drafting of the regulations for which a committee of the College had been sitting.

Affairs of State had already claimed their attention. The services of the College would be placed at the disposal of the Government, which intended to take action in regard to maternity problems, and had asked for assistance and advice from the College. On a matter of domestic policy, the President said that the personnel of the College, its council and officers had necessarily been elected by the original preliminary committee; but within the next few months the present officials would voluntarily resign and would offer themselves along with others duly nominated for re-election by vote of fellows and members. If the College was to make good and to justify its existence, it would need the active support, based on real interest in its endeavours, of every obstetrician and gynæcologist.

The President read to the meeting the oath of membership:—

> I solemnly affirm that I will at all times maintain the welfare and dignity of the College, faithfully obeying in the spirit as well as in the letter the Articles and Regulations, and submitting myself to the lawful authority of the Council. Furthermore, I pledge myself in the practice of the Art of Obstetrics and Gynæcology ever to have regard to the honour of the College and to the welfare of the State.

These words, he said, expressed the ideals of loyalty, progress, and service which inspired their organisation.

THE GENERAL HOSPITAL, BIRMINGHAM:

SESQUI-CENTENARY CELEBRATION.

THE General Hospital at Birmingham was founded in the year 1779 by the single-minded effort of a local physician, Dr. John Ash, F.R.S., whose memory was honoured on Dec. 10th at a notable gathering which included a midday celebration in the Cathedral, an afternoon assembly at the Hospital with orations by Prof. K. F. Wenckebach of Vienna and Lord Moynihan of Leeds, and an evening banquet at which more than 450 patrons, friends, and officers of the hospital were present. For the benefit of guests and others the story of the hospital was told in a Retrospect prepared by the senior consulting surgeon, Sir Gilbert Barling, pro-Chancellor of the University, himself unfortunately prevented by ill-health from attending. His story is a lively and worthy record of the growth of a city's care for its sick poor, side by side with the training of students and nurses and the advancement of medical science, towards their ultimate fusion in the scheme soon to be set on foot for a new hospital at Edgbaston, attached to the University, with every facility for teaching and research—the Golden Age of Medicine, as Sir Gilbert happily phrases it.

In his oration to the assembly Prof. Wenckebach discoursed on the use of the fox-glove by the bedside, with a generous recognition of the pioneer work of Dr. William Withering, a contemporary of Ash. Lord Moynihan told the story of surgery through the ages, recalling that Neolithic man suffered from spinal caries and the present-day Birmingham citizen still ran the same risk by refusing to boil his milk.

The Banquet.

At the banquet, which was a model of smooth organisation, the guests were received by the President of the hospital, Alderman A. H. James, J.P. The toast of The City was proposed by Lord Moynihan, who spoke of the medical men who had "made" the city: Lawson Tait with a leonine personality and the heart of a child; Furneaux Jordan, Jordan Lloyd ("almost a magician"), Sampson Gamgee, blessed alike to surgeon and patient for his introduction of dry dressings; Priestley Smith, dexterous and inventive; down to Gilbert Barling and Haslam. The Lord Mayor, Alderman M. L. Lancaster, J.P., in responding, expressed the hope that the voluntary hospitals would keep pace with the growth of the city and praised the work-people whose annual subscriptions now approached £150,000. Sir John Rose Bradford, in proposing The Birmingham General Hospital, spoke with great feeling of the particular place held by voluntary hospitals in the affection of the British people, and of their dependence on the gifts and devoted service of laymen for their success. Birmingham General Hospital had arisen at the *same remarkable period* which saw the foundation of the Royal Infirmary, Edinburgh, and five of the great teaching hospitals of London. The city was happy to have had men capable of appreciating the great purposes that medicine might be made to serve. Alderman James, in reply, admitted a period of suspended animation *in the life of the Hospital in preparation for the big* scheme ahead of them. The fact that more than one in four of the Birmingham population subscribed to the contributory fund was, he said, a lasting monument to the patriotism and vision of the work-people. Councillor Miss Bartleet, J.P., chairman of the board of management, also replied. Dr. Stanley *Barnes, senior physician,* who received an ovation on rising, proposed The Guests, and Prof. Wenckebach in response thanked for the good cheer and the good fellowship which he and all his fellow guests had enjoyed. A word should be added in praise of the admirable acoustic properties of the Grosvenor Room where the banquet was held.

AN OUTSIDE VIEW OF CONTRIBUTORY PENSIONS.

Dr. E. S. Moorhead, chairman of the welfare supervision board of the Winnipeg Health and Public Welfare Service, has recently been in this country studying the contributory pensions scheme, and has presented a report to his Board. He finds that the scheme is exceedingly popular in this country, and that many more people would like to be included within its scope. He draws attention to the fact that the machinery for collecting contributions was already in operation through the National Health Insurance Act. It is as easy to collect 1s. 6*d.* a week as 9*d.*, and to attach two stamps to a card involves little more labour than attaching one. This gave the scheme a great advantage from its inception, and provided a smooth and successful working. The difficulty in the way of extending it to the whole of the country is just this difficulty, Dr. Moorhead thinks, of collecting the contributions. To throw the scheme open on a voluntary basis would be economically unsound, as the healthy young men would be unlikely to seek admission while the middle-aged man suffering from tuberculosis, *heart disease, or other disability would immediately join,* especially if he had a wife and young children dependent on him. It would also be economically impossible to send round public collectors to the small shop-keeper, the small farmer, the country blacksmith, and the poorly paid clergy, all of whom were anxious to be included in some form of contributory pensions scheme. At first Dr. Moorhead was puzzled on hearing that the premium for men was double that for women, seeing that women live longer and are less likely to be killed by industrial accidents or by exposure. It was explained to him, however, that most of a man's insurance really goes to provide pensions for his widow or children. If he dies without leaving either widow or child under the age of 14, his estate is not entitled to recover any sum from the Government. Women, on the other hand, cease contributions when they marry, unless they continue to work—which is estimated to happen once in seven cases. Dr. Moorhead is *impressed with the fact that England gives the* cheapest industrial insurance in the world, and is prepared to expend for the next 35 years or more an immense sum from State funds in order to put the plan on a sound basis. He feels that Manitoba will have to face the problem of a compulsory pensions scheme and that the difficulties, though great, are not likely to prove insuperable. Any scheme which is not contributory would prove, he thinks, an excessive burden on the tax-payer in a very short time.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

BILLS ADVANCED.

IN the House of Lords on Dec. 3rd, the Poor-Law Bill, a consolidation measure, was recommitted in respect of an amendment made by the Joint Committee which considered the Bill. The amendment was agreed to and the Bill was reported with the amendment to the House. On Dec. 4th and 5th the Bill was agreed to on Report and read the third time. On Dec. 4th a Bill providing for the registration of chiropodists was read a first time. The Royal Assent was given by Commission on Dec. 6th to the Widows, Orphans and Old Age Contributory Pensions Act. On Dec. 5th in the House of Commons, Major ELLIOT'S measure The Education (Scotland) Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 4TH.

Night Baking.

Mr. MANDER asked the Home Secretary whether the Government had now decided how to deal with the subject of night baking.—Mr. CLYNES replied: This subject will be dealt with in the Factories Bill.

Sale of Tuberculous Cows.

Dr. HASTINGS asked the Minister of Agriculture whether *his department had issued any regulations to prevent the* sale of a cow, shown by test to be suffering from tuberculosis, for the purpose of producing milk for sale to the public; and, if not, whether he would consider the adoption of some method, such as branding, so that the purchaser might at least know the condition of the animal he is buying.—Mr. BUXTON replied: The Tuberculosis Order of 1925 requires the notification, and provides for the slaughter, of cows shown to be giving tuberculous milk or excreting tubercle bacilli in other ways, and for the compensation of their owners. Reaction to the tuberculin test does not, however, by itself, bring animals within the scope of the Order as that is not sufficient evidence that they are giving tuberculous milk. I do not consider that the branding of reactors is necessary; intending purchasers can protect their herds by only buying cows which have passed the tuberculin test.

THURSDAY, DEC. 5TH.

Ex-Service Men and Rheumatism.

Mr. RAMSBOTHAM asked the Minister of Pensions how many ex-Service men had been granted pensions in respect of rheumatism; how many of these pensioners had died from rheumatism and heart affection; and in how many cases wives had been granted a pension in respect of their husbands' death.—Mr. *F. O.* ROBERTS *replied:* Awards have been made since 1914 in respect of rheumatism to some 84,700 officers and men. The information asked for in the second and third parts of the question is, I regret, not available.

Vaccination and Nervous Diseases.

Mr. GROVES asked the Minister of Health how many of the cases of nervous disease following within a month of vaccination were vaccinated with Government lymph and how many with other lymph; and whether his department had any reason to suppose that complications had attended the use of foreign lymph more frequently than the use of Government lymph.—Mr. GREENWOOD replied: Of the total number of cases of the kind referred to which have been brought to the notice of my department since 1922, 148 were vaccinated with Government lymph and 37 with other lymph. I have no information as to the lymph used in the remaining 8 cases. With regard to the second part of the question, no information is available as to the extent to which lymph, other than Government lymph, is used in this country and no conclusions can, therefore, be drawn as to the comparative likelihood of complications following the use of Government lymph, and lymph supplied from private sources, respectively.

Prevention of Contagious Abortion in Cattle.

Lieut.-Colonel FREMANTLE asked the Minister of Agriculture if his department issued and recommended the use of a live vaccine as the best preventive against contagious abortion in cattle; how long this had been in use; whether it had increased or reduced the incidence of the disease in cattle; and what steps he proposed to take to ensure the adoption of every measure for the reduction of this pest.—Dr. ADDISON (Parliamentary Secretary to the Ministry of *Agriculture) replied: In herds* in which the percentage of infection of contagious abortion is not high, the Ministry recommends that the disease should be controlled by hygienic measures and the agglutination test for the detection of infected animals. In herds in which infection is heavy, the Ministry advises the immunisation of all non-pregnant animals with the live vaccine. This vaccine has been issued from the Ministry's Laboratory since 1912, and the demand for it indicates that it is serving a useful purpose. The disease does not lend itself to legislative control, and therefore my right hon. friend intends to encourage and assist research workers to concentrate on the discovery of better methods of immunising cattle against the disease.

Milk Service in Schools.

Viscount LYMINGTON asked the President of the Board of Education the number of schools having milk clubs, together with the number of school-children receiving milk under the National Milk Publicity Council's scheme for milk service in schools.—Sir CHARLES TREVELYAN replied: I regret that I am unable to give the noble lord the particulars for which he asks, but I understand that partly as a result of the activities of the National Milk Publicity Council there has, in the past few years, been a considerable extension of these arrangements for supplying milk to children in the schools. Among other places, comprehensive arrangements are in operation at Birmingham and Leeds.

District Medical Officers and Health Committees.

Mr. HACKING asked the Minister of Health whether he would take steps to prevent members of town councils who were also district medical officers under boards of guardians allowing their names to be included on the health committees of boroughs for 1930, when such health committees would be the public assistance committees of the boroughs in which these persons acted as district medical officers; and whether such persons would be prevented from taking part in the arrangements for the setting up of public assistance committees when they were actually paid servants of the Ministry of Health.—Mr. GREENWOOD replied: As the law stands, district medical officers under the poor-law who will be transferred to county councils and the councils of county boroughs under the Local Government Act, 1929, will be automatically disqualified from membership of the council or a committee of the council to whom they are transferred. District medical officers are employed and paid by the boards of guardians and not by my department.

Pauper Lunatics.

Major GLYN asked the Minister of Health the total number of pauper lunatics cared for by the poor-law authorities, and at what cost; what was the number accommodated at the expense of the asylum authorities; what was the number maintained at the expense of the boards of guardians; what was the position of the board of control in regard to the care and supervision of these lunatics; and how these figures compared with 1925, 1920, and 1910.—Mr. GREENWOOD replied: Figures are not available in regard to all the points raised by the hon. and gallant Member, but Table A shows the total number of pauper lunatics in the four years mentioned, and indicates where they were maintained, while Table B shows the expenses incurred in connexion with public mental hospitals. The cost of maintenance falls upon boards of guardians, the remaining expenditure upon local authorities under the Lunacy Acts. Board of guardians recover part of the cost of maintenance from friends and relatives of the patient. The powers and duties of the Board of Control in the case of patients on out-door relief are limited to obtaining a return from the poor-law authorities, and, in the case of lunatics in poor-law institutions, to paying periodical visits. As regards patients detained in county and borough mental hospitals, the Board of Control examine the documents upon which they are received and detained, and also consider periodical medical reports. They also visit the institutions and have general supervision over the arrangements for the proper care of the patients.

TABLE A.—*England and Wales; Total Number of Pauper Lunatics on Jan. 1st in each of the Years Specified.*

Where maintained.	1910.			1920.			1925.			1929.		
	M.	F.	Total.	M.	F.	Total.	M.	F.	Total.	M.	F.	Total.

Inspection of Dairy Farms.

Lieut.-Colonel FREMANTLE asked the Minister of Health how many inspectors were employed by his department in inspection of dairy farms; and how many of the inspectors were qualified veterinary surgeons.—Mr. GREENWOOD replied: Two inspectors are employed by my department in the inspection of dairy farms, and neither of them is a qualified veterinary surgeon. I may add that the only farms inspected by officers of my department are those producing Certified and Grade A (tuberculin tested) milk, and that the examination and testing of cattle on these farms are carried out by qualified veterinary surgeons approved by the department.

MONDAY, DEC. 9TH.

Medical and Surgical Treatment of ex-Service Men.

Sir GEORGE BOWYER asked the Minister of Pensions whether he intended to take over all medical and surgical treatment of ex-Service men, providing, where necessary, full-time medical officers for the purpose.—Mr. F. O. ROBERTS replied: My department has authority under the Royal Warrants to provide such treatment only as is not otherwise provided. I could not, therefore, adopt the course suggested by the hon. and gallant Member without duplicating other statutory arrangements for the provision of treatment which are in operation under the National Health Insurance Acts and other enactments.

Maternity Benefit.

Mr. KEDWARD asked the Minister of Health whether he was proposing to make any change in the method of granting maternity benefit; and whether any reduction in the present amount of £2 was being considered.—Miss LAWRENCE

(Parliamentary Secretary to the Ministry of Health) replied: The whole question of the arrangements for maternity benefit under the scheme of National Health Insurance is under consideration, but my right hon. friend is not yet in a position to say what alterations, if any, will be made.

Drinking Water-supply in Villages.

Mr. GRANVILLE asked the Minister of Health if he was prepared to consider area schemes for providing employment in the building of rural cottages and the provision of a system for the supply of drinking water in villages.—Miss LAWRENCE replied: My right hon. friend proposes to give special consideration to the question of rural housing in connexion with forthcoming legislation. As regards rural water-supplies, my right hon. friend will be prepared to consider any schemes, and I may point out that the Government have recently announced special terms of assistance as part of their unemployment proposals.

Indian Army Veterinary Corps.

Major GRAHAM POLE asked the Secretary of State for India how many Indians had been admitted to the commissioned ranks of the Indian Veterinary Corps since that arm of the Indian Army was opened to Indian gentlemen.—Mr. BENN replied: No Indian has yet been commissioned in the Indian Army for employment in the Indian Army Veterinary Corps, but one candidate has been selected and is now under training in this country for that purpose.

TUESDAY, DEC. 10TH.

Training and Employment of Midwives.

Viscountess ASTOR asked the Minister of Health whether it was intended to introduce legislation embodying the scheme outlined in a memorandum of the British Medical Association for a national maternity service for England and Wales, the findings of the Royal Commission on National Health Insurance, and the recommendations of the report of the departmental committee on the training and employment of midwives.—Miss LAWRENCE replied: My right hon. friend is not yet in a position to make a statement on this subject.

Registration of Mental Nurses.

Mr. REMER asked the Minister of Health if his attention had been called to the fact that mental nurses in possession of the Royal Medico-Psychological Association's certificates did not receive admission to the register kept under the Nurses' Registration Act, 1919; and would he issue an order to rectify this position.—Miss LAWRENCE replied: I would refer the hon. Member to the reply given him on Nov. 28th. My right hon. friend is not empowered to issue any order in this matter.

Death after Vaccination.

Mr. FREEMAN asked the Minister of Health whether his attention had been called to the case of Clarence Morris Martin, who died on Nov. 14th, having been vaccinated on Oct. 9th, and that the coroner reported the death was caused by septicæmia following the accidental breaking off of the vaccination scab; had he instituted inquiries into this case, and had he anything further to report.—Mr. GREENWOOD replied: My attention has been called to this case which occurred at Southampton, and inquiries have been made into the matter. The death took place on Nov. 10th, the cause of death certified by the coroner, after an inquest, being as stated in the question. I am satisfied that death was due to accidental infection of the site of the vaccination from some extraneous source, and that no blame attaches to the public vaccinator or to the lymph used.

BRISTOL HOSPITALS.—The 193rd annual report of the Bristol Royal Infirmary (380 beds) shows that last year 8082 patients were admitted to the wards, and that the out-patients numbered 99,310. Of the 1,807 maternity cases 810 were admitted, the others being attended to in their own homes. Of the total births in Bristol 21 per cent. received attention at the infirmary. Very satisfactory results are stated to have attended the work of the cancer research department, and the "Bristol Royal Infirmary lead treatment" has "gone all over the world."—At the Bristol General Hospital there is a new out-patients' department and a new children's ward and operating theatre are being provided. A new ward for the treatment of male accident and other surgical cases has been necessitated by the long waiting-list of surgical cases. The local poor-law hospitals have no vacant beds available for the overflow of surgical cases. The cardiac research centre has been busily engaged. During 1928, £9763 was paid by, or on behalf of, patients, but the adverse balance on ordinary expenditure account exceeded £12,000.

Medical News.

UNIVERSITY OF CAMBRIDGE.—On Dec. 6th the following degrees were conferred:—

M.D.—*W. L. Barnett, K. E. Harris, J. D. M. Stewart, and R. A. Hickling.

B.Chir.—W. E. Mashiter and C. G. Townsend.

* By proxy.

UNIVERSITY OF BRISTOL.—At recent examinations the following candidates were successful:—

M.D.

W. A. Gornall.

FINAL EXAMINATION FOR M.B., CH.B.

Part II.—*J. J. J. Giraldi, J. E. Newton, and N. C. Tanner. The following passed in groups which completed their examination: N. L. Price, N. D. Gerrish, and Mabel F. Porter. *In Group II. only*: R. M. Norman.

* With second-class honours.

Part I., including Forensic Medicine and Toxicology.—J. S. Adamson, T. A. Barnabas, J. E. Brown, H. L. Cleave, J. L. S. Coulter, C. J. N. Davis, F. W. A. Fosbery, L. R. Jordan, J. A. Kersley, R. H. Moore, Elizabeth S. G. Owen, C. N. Royal, and W. A. F. Taylor.

Part I.—L. P. Ashton.

FINAL EXAMINATION FOR L.D.S.

J. D. Galloway.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—On Dec. 2nd the following were admitted Fellows of Faculty: Alfred Mackenzie Clark, Joshua Ferguson, William David Henderson Stevenson, and Rosie Swamikan.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At the Annual Meeting of the College on Dec. 5th Sir Norman Walker was elected President, Dr. Robert A. Fleming was nominated Vice-President, and the following were elected Members of Council for the ensuing year: Dr. G. Lovell Gulland, Dr. John Orr, Dr. William Fordyce, Dr. Edwin Bramwell, and Dr. Fergus Hewat. At the Extraordinary Meeting which followed, Dr. John Orr and Dr. William Fordyce were elected Representatives of the College on the Board of Management of the Royal Infirmary of Edinburgh.

WEST LONDON HOSPITAL.—The annual report states that the 3028 in-patients in 1928 stayed on an average 20·57 days instead of the 21·75 days of the previous year, a shortening which enabled a larger number of patients to be received. They cost £3 8*s.* 7*d.* per week, an increase of 1*s.* 4*d.* There were 275,730 out-patient attendances; each patient cost 8*s.* 10*d.* A new casualty department is being provided at a cost of between £4000 and £5000, and the new department for venereal diseases has cost £14,000. The work of the post-graduate college is still much hampered by lack of adequate accommodation.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The annual dinner of the school was held at the Savoy Hotel, London, on Thursday, Dec. 5th; Mr. Joseph Cunning, senior surgeon to the hospital, was in the chair and presided over a great assembly of those officially connected with the hospital, including students, and a large number of guests.

Lady Emmott proposed Prosperity to the School and Hospital, having taken Lord Byng's place, who was unavoidably absent. The audience, she said, must be experiencing the sentiment aroused when, on arriving at a theatre, they found a notice to say that the principal part was going to be played by a substitute; further, she did not feel qualified to speak, being only a lay-woman, as to the scientific attainments of the students, although she was able to compliment them warmly on the excellence of the entertainments which were given each Christmas. Lady Emmott regretted the difficulties made by the metropolitan teaching hospitals with regard to the admission of women students, although this attitude made the work that was done in the School of Medicine for Women at the Royal Free Hospital more than ever valuable. She concluded by paying tribute to the men members of the medical staff for their hearty coöperation in efforts that were being made, and successfully made, to help women students, while she knew that she was right in saying that the students at the Royal Free Hospital were making a fine response.

Mr. Cunning, in reply, called attention to the zeal and efficiency of past physicians and surgeons attached to the staff, mentioning in particular the manner in which Sir James Berry had secured by his pertinacity the erection of the operating theatres. In reviewing more recent developments he said that a new pathological department was urgently needed and that funds were being raised for that purpose, while the Eastman Dental Clinic had nearly reached completion. He closed by paying a warm tribute to the practical services and generosity of Lord Riddell and Sir Albert Levy.

Dr. Chodak Gregory proposed the toast of the Guests, and said that gratitude was due to Lady Emmott for taking Lord Byng's place and proposing the chief toast of the evening. She reminded the audience that Lady Emmott was both a member of the association of the medical school and a member of the board of management of the hospital, and was therefore well posted in her facts. Enumerating the guests present she selected for special mention Sir Walter Schröder, whose kindness to the young house officers who found themselves in the coroner's court was invariable. Other guests to whom she alluded by name were Dr. Ethel Bentham, a former student of whom the school was proud, as a Member of Parliament; Dr. Catherine Chisholm, representing the Manchester Babies Hospital, who, she said combined the scientific investigation of the infant with the human treatment of the baby; Dr. Deller, the Principal of the University of London, and Mr. Rew, the secretary of the Conjoint Examination Board, whose names had a melancholy association with examinations; Miss Strachey, the Principal of Newnham, whom she congratulated on sending to the Royal Free certain of her own old students; and Lady Rhondda, whose championship of the cause of the working woman was known to all. She associated the toast with the names of Sir Patrick Hastings and Lady Rhondda.

Lady Rhondda, in reply, recalled the history of the school, and made special reference to the Marie Curie Hospital for the treatment of cancer which was staffed from the Royal Free.

The health of Mr. Cunning was proposed by Dr. Elizabeth Bolton, senior surgeon to the Elizabeth Garrett Anderson Hospital, who recalled the debt which the students at the Royal Free owed to the clinical teaching of the chairman, teaching which, she said, was embodied and condensed in a volume known to many generations of students as "little Cunning." Mr. Cunning briefly replied and invited the company to adjourn to the ball-room which promptly became crowded, and remained so until a late hour.

UNIVERSITY OF OXFORD: *G. H. Hunt Scholarship.*—This Scholarship is awarded without examination every second year to a graduate in medicine of the University (of either sex) who has not exceeded five years from the date of passing the final examination for the B.M. degree. Its value is £100, or such smaller sum as two years of the income of the Fund provides. Candidates are required to travel abroad for not less than three months for clinical study or research in medicine. Preference is given to those intending to be surgeons or general practitioners. The next election will be made in April, 1930, and candidates must apply to the Dean of the School of Medicine before Feb. 11th, 1930.

ROYAL SURGICAL AID SOCIETY.—This Society, which was founded in 1862 to supply surgical appliances to the poor, held its annual meeting at the Mansion House last week. The report stated that the total income had been £56,670, and the expenditure exactly £1000 less. During the year 29,262 patients were assisted, and 40,254 surgical appliances supplied at a cost of £16,917.

A CHILDREN'S WELFARE CLINIC.—At the quarterly court of the London Hospital last week Lord Knutsford, the chairman, reported that £3000 had been obtained towards the £4700 required to reconstruct the children's welfare clinic. The present clinic is so overcrowded as to be "a scandal." The Queen has given £250, and Sir Albert Levy has undertaken to contribute £125 a year for 16 years towards the maintenance of the clinic.

INSTRUCTION FOR D.P.H.—A three-months' course of lectures and demonstrations on clinical practice and in hospital administration will be given at the North-Eastern Hospital, St. Ann's-road, Tottenham, London, N., by Dr. F. H. Thomson, the medical superintendent, on Mondays and Wednesdays, at 4.45 P.M., and alternate Saturdays at 11 A.M., from Jan. 6th, 1930. Application should be made to the Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C. 4.

SCOTTISH WOMEN'S WAR HOSPITALS.—At a meeting of the Scottish Women's War Hospitals at the Royal Free Hospital last week the Duchess of York received purse containing £6285 for a scheme to commemorate heroic Scots women. The money will be used to build, equip, and endow a new ward in the maternity wing of the Royal Free Hospital and a maternity centre at Islington to be named after the Duchess. Each bed will be named after a unit of the Scottish Women's Hospitals, which worked in most of the fields of operation during the war, or after a member who gave her life in service. One of them will be dedicated to the memory of the founder of the hospitals, Dr. Elsie Inglis.

HARVEIAN SOCIETY: *Buckston Browne Prize.*—The President and Council of this Society have awarded the biennial Buckston Browne Prize of £100 and medal to Dr. C. Bruce Perry, for an essay on "Chronic Streptococcal Illnesses." Proximo Accessit: Dr. R. Cove-Smith.

BERNHARD BARON TRUST.—The annual distribution of grants from the £500,000 trust created by the late Mr. Bernhard Baron has lately been made. Contributions have been received by about 270 hospitals, orphanages, and kindred institutions, the total being £36,530.

LEEDS HOSPITAL FOR WOMEN.—From next Jan. 1st, four wards will be set apart for paying patients, at a charge of 5 guineas a week. Surgeons' fees will be on a reduced scale. There will be not more than two patients to a ward, and no separate cubicles.

DANGEROUS DRUGS ACT PROSECUTION.—Richard William Starkie, whose name was removed from the Medical Register in 1922, and who was stated by the police to have been at one time a police surgeon, and to have been in prison for administering a noxious drug, was sentenced at Maidenhead on Dec. 2nd to 12 months imprisonment for an offence under the Dangerous Drugs Act. The bench at first made the sentence one of hard labour, but subsequently altered this to imprisonment in the second division.

PITHEAD BATHS AT TWOPENCE A WEEK.—On Dec. 7th at the Grassmoor Collieries, New Chesterfield, the Minister of Mines, Mr. Ben Turner, opened pit-head baths of the most modern type. They have cost £14,000, which is provided by the Miners Central Welfare Committee, and the Grassmoor Colliery Company will supply water, electricity, and gas cost free. There is accommodation for 1200 miners and the cost will be twopence a week which will be deducted from their wages.

HOSPITALS AND MOTOR ACCIDENTS.—In the quarter ending with Sept. 30th last motor accident cases cost the Royal Free Hospital £209, of which only £35 was refunded to the charity.—Between April 1st and Oct. 30th last Sheffield Royal Infirmary and Sheffield Royal Hospital treated between them 470 motor accident cases.

BRADFORD ROYAL INFIRMARY.—The annual report for 1928 mentions that approximately 450 persons die annually in Bradford from cancer. An appeal for £20,000 to provide an adequate supply of radium had been sufficiently well responded to to justify the purchase of 1 gramme, and Dr. Chester-Williams, of the London Radium Institute, was appointed radium specialist.

ROYAL GWENT HOSPITAL.—Last year this hospital at Newport, Mon., had a surplus of income over expenditure of £5700 which was used to discharge the debt on the building extension fund. The income was £31,238, the highest in the history of the hospital. The workmen's fund produced £13,400, an increase in two years of nearly 50 per cent. During the year 2257 patients were admitted; there were 6410 cases in the casualty department, and 20,401 attendances in the venereal department.

HOSPITAL ACCOMMODATION AT HARPENDEN.—The Hertfordshire village of Harpenden is at present served by a nursing centre. Mr. Halley Stewart, a local resident, regards this as inadequate to the growing needs of the neighbourhood and, by way of celebrating his approaching ninety-second birthday, has offered 67 acres of land, his own house, and three cottages for the foundation of a cottage hospital.

EYE, EAR AND THROAT HOSPITAL FOR SHROPSHIRE AND WALES.—Last year this Shrewsbury hospital treated 6840 patients, a large increase, of whom 1351 were in-patients. Diseases of the eye and errors of refraction accounted for 4605 of them, and there were 1070 major operations, 88 of which were for cataract; there were 11 cases of ophthalmia neonatorum. The medical officer's report states that the appointment of an honorary dental surgeon has been of great value both from a diagnostic and a curative aspect.

DAVID LEWIS EPILEPTIC COLONY.—At the annual meeting of the David Lewis Manchester Epileptic Colony at Warford, Alderley Edge, on Dec. 5th, it was stated that the demand for accommodation in the colony continued to increase. Although the majority of the people who took up residence in such a colony did not cease to have fits almost all benefited very greatly. The inmates had peace of mind, the enjoyment of life, and the feeling of being useful, without which they must inevitably deteriorate in happiness, in intelligence, in good conduct, and in health. The group system for epileptics made them feel normal, and instead of depressing them it had the opposite effect.

Medical Diary.

SOCIETIES.

HUNTERIAN SOCIETY.

MONDAY, Dec. 16th.—8.30 P.M., Discussion on The Whitlow and Its Complications, opened by Mr. V. Zachary Cope and Mr. H. W. Carson, preceded at 7.30, by Dinner at Simpson's Restaurant, 2–3, Bird-in-Hand Court, 77, Poultry, Cheapside, E.C.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-street, W.C.

FRIDAY, Dec. 20th—5 P.M., Discussion on The Public Health Service and its Future, introduced by Prof. H. R. Kenwood and Prof. W. W. Jameson.

CHELSEA CLINICAL SOCIETY.

TUESDAY, Dec. 17th.—8.30 P.M., Discussion opened by Dr. G. Murray Levick on Present Position and Possibilities of Physical Treatment, preceded, at 7.30, by Dinner at the Hotel Rembrandt, Thurloe-place, S.W.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Dec. 16th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

TUESDAY, Dec. 17th.—5 P.M., Dr. J. A. Drake: Urticaria.

THURSDAY.—5 P.M., Dr. H. G. Burford: Pathology Demonstration.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Dec. 18th.—4 P.M., Prof. E. L. Collis: Industry in Relation to Personal and Public Health.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Dec. 20th.—4 P.M., Mr. F. W. Watkyn-Thomas: Fractured Skull and the Aural Surgeon.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, Dec. 18th.—4.15 P.M. (in the Royal Infirmary), Mr. James Taylor: Surgical Cases.

Vacancies.

For further information refer to the advertisement columns.

Acton Hospital, Gunnersbury-lane.—Res. M.O. £150.

Barnsley, Beckett Hospital and Dispensary.—H.P. £140.

Barnstaple, North Devon Infirmary.—H.S. At rate of £150.

Birmingham General Hospital.—Two Res. Anæsthetists. Each £120. Also Anæsthetist. £250.

Birmingham, Queen's Hospital.—Res. H.S. to Ophth. and Ear, Nose, and Throat Dept. Res. H.S. to Cas. Dept. Each £70. Also Hon. Phys.

Bradford City.—Asst. School Dentist. £450.

Bristol General Hospital.—Two H.P.'s, two H.S.'s, Res. Obstet. O., H.S. to Special Depts. Each at rate of £60. Also Cas. H.S. At rate of £80.

Burnley, Victoria Hospital.—H.S. At rate of £125.

Bury St. Edmunds, West Suffolk General Hospital.—H.S. £150.

Cairo, Egypt, Giza Memorial Ophthalmic Laboratory.—Pathologist and Bacteriologist. L.E. 1200.

Cardiff, Prince of Wales' Hospital.—Res. Surg. £350.

Carlisle, Cumberland Infirmary.—Pathologist and Bacteriologist. £900.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. At rate of £120 and £100 respectively.

Chester, Wrenbury Hall Tuberculosis Training Colony.—Res. H.P. £250.

Chesterfield and North Derbyshire Royal Hospital.—Cas. H.S. At rate of £200. Also three H.S.'s. At rate of £100–£175.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Laryngologist.

Coventry and Warwickshire Hospital.—Res. H.S. £125.

Dorchester, Dorset Mental Hospital, Herrison.—Jun. Asst. M.O. £300.

Durham County Hospital.—Jun. H.S. At rate of £120.

Edinburgh Royal Infirmary, Ophthalmic Dept.—Sen. Clin. Asst. and Clin. Tutor. £145. Also two Clin. Assts. Each £200.

Exeter, Royal Devon and Exeter Hospital.—Hon. Asst. Phys.

Grove Park Hospital, Lee, S.E.—Jun. Asst. M.O. £500.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Huddersfield Royal Infirmary.—Res. Surg. O. £200.

Hull Royal Infirmary.—Second H.S. At rate of £150. Also Sen. H.P. At rate of £200.

Kidderminster and District General Hospital.—H.S. £150.

Lancashire County Council.—Asst. County M.O., &c. £800.

Leicester Royal Infirmary.—Hon. Phys. and Hon. Surg.

London Hospital, E.—Cardiographic Dept., Paterson Research Scholar. £100.

London University.—Geoffrey Duveen Travelling Studentship. £150.

Manchester Ancoats Hospital.—Asst. Pathologist. £350. Also Med. Reg. and Surg. Reg. Each £100.

Manchester, Baguley Sanatorium.—Sen. Asst. M.O. £500. Also Asst. M.O. £350.

Manchester, County Mental Hospital, Prestwich.—Asst. M.O. £500.

Manchester Royal Infirmary, Roby-street.—Anæsthetist. £25.

Manchester, Salford Royal Hospital.—Res. Surg. O. £200. H.S. At rate of £125. Also H.S. to Aural, Skin, &c., Depts.

Miller General Hospital, Greenwich-road, S.E.—H.P. and H.S. Each at rate of £125.

Newark Hospital and Dispensary.—Res. H.S. At rate of £150.

North Wales, Ruthin Castle.—Jun. Res. Phys. At rate of £200.

Perth Infirmary.—H.P. £75.

Portsmouth, St. Mary's Hospital, &c.—1st Asst. Res. M.O. £350.

Princess Louise Kensington Hospital for Children, N. Kensington. H.S. At rate of £75.

Royal Free Hospital, Gray's Inn-road, W.C.—Sen. and Jun. Clin. Assts.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.

Ryde, Royal Isle of Wight County Hospital.—Res. H.S. £180.

St. John's Hospital, Lewisham, S.E.—Orthopædic Surgeon.

Shrewsbury, Royal Salop Infirmary.—Res. H.S. and Res. H.P. Each at rate of £160.

Singapore General Hospital.—Anæsthetist. £840.

Swansea County Borough.—Asst. M.O. £600.

University College Hospital, Gower-street, W.C.—Hon. 1st Asst. for Ear, Nose and Throat Dept.

Walsall General Hospital.—Cas. H.S. At rate of £120.

Walthamstow Borough Education Committee.—School Dentist. £500.

Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.

Westmorland County Council.—Asst. County M.O. £800.

Wigan Infirmary.—Third H.S. £150.

Wolverhampton, Royal Hospital.—Cas. O. and Res. Anæsthetist. At rate of £125. Also H.S. for Ear, Nose and Throat Dept. At rate of £150.

Wrexham and East Denbighshire War Memorial Hospital.—Hon. Surgeon to Ear, Nose and Throat Dept.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Redruth (Cornwall); Abingdon (Berks); and at Dover (Kent).

The Home Secretary gives notice that there will shortly be a vacancy for a Medical Referee under the Workmen's Compensation Act, 1925, for the Dundee district of the Sheriffdom of Forfar. Applications for the post from duly qualified medical practitioners should be addressed to the Private Secretary, Scottish Office, Whitehall, S.W. 1, and should reach him not later than Dec. 24th, 1929.

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the Districts of the Bristol, Wells and Weston-super-Mare County Courts (Circuit No. 54). Applications from surgeons should reach the Private Secretary, Home Office, Whitehall, S.W., not later than Dec. 31st.

Births, Marriages, and Deaths.

BIRTHS.

GARNHAM.—On Dec. 4th, the wife of Dr. P. C. C. Garnham, of a daughter.

SHIRES.—On Dec. 5th, at Welbeck-street, W., the wife of Dr. Bertram Shires, of a daughter.

MARRIAGES.

DANBY—ARKELL.—On Dec. 7th, at Holy Apostles Church, Cheltenham, Alfred B. Danby, F.R.C.S., of Birmingham, son of Mr. and Mrs. Danby, of Wellington, New Zealand, to Victoria, youngest daughter of the late James Arkell, of Highworth, Wilts, and of Mrs. Arkell, Oak Hill, Charlton Kings, Cheltenham.

READ—GILL.—At Linkinhorn Parish Church, Cornwall, on Saturday, Dec. 7th, by the Rev. G. Rhys, assisted by the Rev. C. C. C. Bosanquet, Charles David Read, M.B., F.R.C.S.E., 1, Park-crescent, London, W.1., to Mabyn Gill, The Old House, Rilla Mill, Callington, Cornwall.

DEATHS.

ATKINSON.—On Dec. 6th, at St. Thomas's Hospital, Walter Alexander Atkinson, M.D., B.S., of Camberwell New-road, S.E., aged 66.

CUMMING.—On Dec. 7th suddenly, George William Hamilton Cumming, M.D., of "Overton," Torquay.

HUTCHISON.—On Dec. 4th, at Cheadle, Cheshire, James Hutchison, M.D., formerly of Norbury, S.W.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE FOUNDER OF THE ROTUNDA.

THE Rotunda Hospital, Dublin, which is appealing for £20,000 to bring its buildings and equipment fully up to date, was founded early in the eighteenth century by a medical man, Dr. Bartholomew Morse, a native of Maryborough in the Queen's County. Morse was born in the year 1712, and after making a special study of obstetrics he settled in Dublin, where his compassion was aroused by the wretched condition of poor women approaching confinement who found themselves without medical aid. Having resolved to do all in his power to have a hospital established in which relief and nursing should be gratuitously supplied, he travelled France, Holland, and other parts of Europe to study hospital systems.

On his return to Dublin he took a house in St. George's-lane (now South Great George's-street), furnished it with 24 beds, and in 1745 opened there the first hospital of the kind ever established, it is said, in the British Dominions. The expenses of the undertaking were defrayed chiefly out of his own purse, supplemented by the proceeds of lotteries, plays, concerts, and oratorios. Dublin was exceedingly musical in those days, and as hospitable as it is in our own generation. Morse induced many foreign vocalists and instrumentalists to come over to Dublin, among them the Italian Castruccio, who, after delighting everyone with his performances which he gave for little or nothing, sank into poverty and died in Dublin, too proud to let anyone know he was in want. So great was the concourse of people at his funeral in St. Mary's Churchyard, Jervis-street, that it is said the parish beadle was crushed to death. When the hospital in George's-lane became too small to accommodate all who sought admission Morse secured a plot of waste ground in Great Britain-street more than four acres in extent, and in August, 1748, began to lay out at a cost of about £20,000 of his own money a garden which should be an attractive place of promenade for the nobility and gentry residing in the neighbourhood. Shrubberies were planted, ornamental walks laid out, pavilions and a coffee-room erected. Fountains, statues, and coloured lamps adorned the walks, and orchestral performances brought in many hundreds of pounds annually. When he had £500 in hand, Morse started the magnificent pile of the Rotunda as we now know it. Up to the end of 1755 he collected £11,004, but this sum, added to the whole of his personal fortune, being insufficient, he petitioned the Irish Parliament for aid and obtained two grants of £6,000 each with a further award of £2000 for himself as a recognition of his exertions in the cause of humanity. On Dec. 8th, 1757, the upper ward of 50 beds was opened by the Duke and Duchess of Bedford, the ceremony being followed by a concert of vocal and instrumental music. From these concerts in the gardens the hospital continued to benefit to the extent of £4000 a year. Morse himself only just lived to see the fruition of his efforts. He fell ill in the winter of 1758 and died in February, 1759, almost without personal estate.

THE DIFFERENTIATION OF THE PROPERTIES OF FOODSTUFFS.

THE various nutritive constituents of food and their biological values, together with chemical tests to identify each, are fully dealt with in a small book[1] recently published from the department of physiology of King's College of Household and Social Science. Methods of analysing foodstuffs in order to isolate their constituents are carefully explained, with full details of the chemical reagents required and the minimum of apparatus, the latter being of such simplicity that it could be procured at the remotest store and set up in any classroom. The chemical changes involved in digestion and the effects induced by cooking foods are illustrated by suitable experiments. Finally, food tables are given and dietary standards are discussed. Teachers of domestic science will find this book of great assistance in preparing practical class demonstrations on the properties of food.

"FISGARD."

To the Editor of THE LANCET.

SIR,—I notice in your Services column in THE LANCET last week an appointment to a ship *Fisgard*. Being curious about this name I consulted many reference books such as biographies, gazetteers, lists of battles, encyclopædias, and so forth without discovering the name mentioned. In the Navy List it appears as *Fisgard* and even in 1864 I see there was a *Fisgard* at Woolwich. I have also just seen a new catalogue of prints which describes an aquatint in colours of the capture of *Immortalité*, Oct. 20th, 1798, by H.M.S. *Fishguard*, Capt. T. B. Martin, on his way to Brest after the attempted invasion of Ireland on Oct. 12th, 1798. But the old Navy List says a medal was issued for the capture of the French frigate *L'Immortalité*, Oct. 20th, 1798, *Fisgard*, Capt. Thomas Byam Martin. I suppose by this it was not "*Fishguard*" but the question remains unsolved. What is the origin of the name? Perhaps one of your erudite readers could supply an answer.

I am, Sir, yours faithfully,

London, Dec. 7th, 1929. ETYMOLOGIST.

THE SCHOOLMASTER AND THE FIRST M.B. EXAMINATION.

AT the annual general meeting of the Incorporated Association of Headmasters, to be held at the Guildhall, London, on Jan. 3rd, Dr. Terry Thomas, headmaster of Leeds Grammar School, will propose:—

(*a*) That the Incorporated Association of Head Masters agrees with the General Medical Council that a boy should have attained the age of 17 before entering himself at a University or a Medical School recognised by one of the licensing bodies.

(*b*) That a pass at the main subject standard in a Higher School Certificate Examination in any of the subjects of the First Professional Medical Examination should be accepted, subject for subject, for the purposes of exemption from such subjects in the latter Examination.

WHITAKER'S ALMANACK.

THE sixty-seventh annual volume of Joseph Whitaker's Almanack still contains the astronomical and other cosmic data which have made it the boon companion of seamen and star-gazers for half a century, but it also contains the current everyday knowledge which makes it (in the immodest but perfectly true words of the editor-in-chief) indispensable to all who speak or read the English language. Civilisation would suffer appreciably if the files of the Almanack were lost in a cataclysm. While it contains classified information about the metropolitan hospitals and other medical information which may be of value to the public, its value to the medical man is as a vade-mecum of general information. The new features of the present issue include the names of the new Ministry and of the Members of the new House of Commons which alone make it worth its price. The Almanack has been published in the first week of December in order to make it available as a Christmas or New Year's gift to friends and kinsmen overseas. The price is 6s. for the complete edition of 928 pages, 3s. for the shorter edition of 608 pages in paper cover.

CHOCOLATES AND COCOA.

Messrs. Cadbury Bros., Ltd., have added to their large range of chocolates several preparations with new and palatable flavours, and these are included in a selection known as "Princess Elizabeth" assortment. These chocolates should prove popular, as they supplement the "King George" and other favourite assortments. Other samples sent to this office of recent invention included the new "Holiday" slab chocolate, and a conserve containing almonds and raisins; the well-known Bournville Cocoa, and a new beverage "Cadbury's Cup Chocolate," which is claimed to possess the virtues of delicacy and flavour associated with French *chocolat*, while it can be made instantly with boiling milk. Special attention has been given by the firm to the appearance and packing of their wares, while all the new productions are up to their high-class standard.

Appointments.

CATCHPOOL, DOROTHY M., M.B., B.S. Lond., has been appointed Medical Officer of Health for Friern Barnet.

MCCURRICH, H. J., M.S., M.B. Lond., Hon. Surgeon to the Hove Hospital.

New Sussex Hospital for Women and Children, Brighton: MANLEY, M. M., M.B., B.S. Lond., House Physician; ROBINSON, M. M. F., M.B., B.Ch., B.A.O. Belf., House Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: D'ALTON, R., L.R.C.P. Irel., L.R.C.S. Irel (Ammanford, Carmarthen); SECCOMBE, C. W., L.R.C.P. Lond., M.R.C.S. (Southall, Middlesex); and ROBERTS, J., M.B., Ch.B. Liverp., F.R.C.S. Eng., Hon. Asst. Laryngologist, Royal Infirmary, Liverpool.

---

[1] Properties of Food. By W. M. Clifford, M.Sc. Lond., Assistant Lecturer and Demonstrator in Physiology, King's College of Household and Social Science; and V. H. Mottram, M.A. Cantab., Head of the Department of Physiology in the College. London: University of London Press. Pp. 128. 2s. 6d.

Huxley Lecture

ON THE

CRYSTAL STRUCTURE OF ORGANIC SUBSTANCE IN ITS RELATION TO MEDICINE.

Delivered at Charing Cross Hospital on Nov. 28th, 1929,

BY SIR WILLIAM BRAGG, K.B.E., D.Sc., F.R.S.,
DIRECTOR OF THE ROYAL INSTITUTION OF GREAT BRITAIN AND OF THE DAVY-FARADAY RESEARCH LABORATORY.

THE choice of a subject for a lecture in honour of Huxley is no light matter. Perhaps the best test that can be applied in order to determine its suitability is to ask whether Huxley himself would have been interested in it. I cannot but think that the opening out of a new means of inquiry into the structure of living substance would have attracted his attention. It is true that we are only at the beginnings of such a movement; but already it is possible to see some features of Nature's designs which hitherto have escaped us, and the future seems to contain most attractive promises. It is my hope that I may succeed during the hour that is allowed me in making plain the prospect of gain to biological science; and in the end to medicine. That which I have to set out is not yet, of course, closely related with medical practice; but in the end it must form a link in the chain which connects the medical care of the body with the elements of which the body is built.

THE NEW X RAY ANALYSIS.

The new X ray analysis deals with matters which have hitherto been beyond our power to examine. Of atoms and molecules as independent individuals in the fluid or gas our knowledge is relatively wide, for it has been the province of chemical and physical science to extend it. With those larger structures which the microscope reveals the needs of biology have forced us to become acquainted; we gather all the knowledge that we can respecting the primary cell and its extensions. But between these two ranges of study is a great gap, where we have hitherto lost sight of the processes of construction. What is there, we may ask, between the individual molecules and those structures which must contain millions of molecules if the eye is to detect them by optical means, which fulfil complicated functions, and which have properties that depend on details of design for ever invisible?

It is here that the X rays put new means of inquiry into our hands. We do not handle them very well as yet; we have to learn to do so. But we have one highly satisfactory source of encouragement. The new science is an exact science; its indications and measurements are not vague and ill-defined in outline; they are arithmetical and precise with a sharpness of definition which we cannot yet use to the full. It is the power of interpreting what is presented to us that lacks development. The ore is rich but we have to find out how to treat it if we are to extract the full value of its contents.

ORDERED ARRANGEMENT OF MOLECULES.

The analysis of structures by X rays rests on two simple facts. The first of these is a most remarkable and widespread tendency in Nature to regularity in the arrangements of molecules. If we did not suspect this before, the X ray analysis has now forced it upon us. The tendency varies in intensity. Although molecules are always drawn together, the agitation of thermal movement may prevent them from settling into position, as, for example, in a molten substance. Or molecules may be surrounded by crowds of other molecules which keep them apart, or even act upon them so as to reduce their mutual attractiveness, as when a substance is in solution. When, however, the tendency is allowed to develop, the molecules pack themselves together according to some regular pattern. Usually the pattern is surprisingly simple; in a very large number of substances two or four or some other small number of molecules are enough to complete the pattern which, repeated through space in all directions, forms the basis of the solid body. Now the solid body is of immense importance. The fluid and gaseous forms of matter have also their importance, and the researches of physics and chemistry have explained to us many of their properties in terms of their composition. But we have known very little of the way in which the properties of the solid depend on its composition; chemistry and physics have been silent on the subject. If solid bodies are always inclined to base their structure on regularity of arrangement during their first formation, and to complete it afterwards when they have the chance, which is indeed the case, it is clear that the regularity must be a powerful factor in the determination of their characters. Such a universal feature of Nature's designs cannot be without purpose and effect. Indeed we are amply familiar with the fact in common practice. The properties of a steel depend greatly on this molecular arrangement; to use a more common phrase, they depend on the state of crystallisation. The so-called "crystal" is nothing more than a body in which this arrangement is carried to such an extent that the result is visible. The metallurgist has long made use of the microscope to study the crystalline condition of his metals and alloys and is fully aware of its fundamental importance. He is now using the X ray methods because they give him much exact information about the crystallisation which he could not obtain before. My hope and expectation is that the biologist will soon be following the same practice; indeed a beginning has already been made.

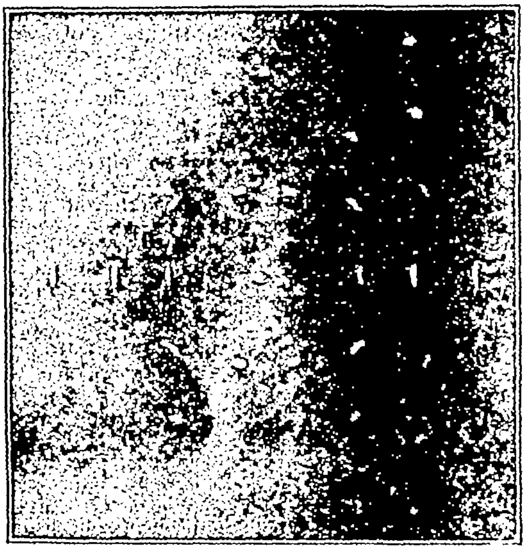
This tendency to arrangement is of universal occurrence. It is the first condition of solid growth. It is quite rare to find that the X rays when applied in the search for it are unsuccessful; and when they fail it is probable that the X ray technique is alone at fault. When molecules begin to group themselves together in many places at the same time, in the same mass of material, and when these nuclei grow into crystals which touch each other, the meeting systems will not generally be in mutual alignment. The body will consist of a multitude of minute invisible crystals irregularly oriented with respect to each other. When these minute crystals consist each of a few molecules only the X rays find it difficult to reveal them. But when a few hundred or even a few score of molecules have joined together in each crystal the task is easy, and the X rays are able, as we shall see, not merely to show the regularity of arrangement which has come about, with various details as to its nature, but also to give a good idea of the size of the aggregates; each of which, it is to be remembered, is invisible even in the microscope. A single crystal weighing as much, say, as a milligramme is at present the ideal body for investigation, but it is not often to be obtained, especially in the case of the constituents of living bodies.

This, then, is our first fact: this universal tendency to arrangement of which we have only lately been able to perceive the extent. It is not merely in the obvious crystal, diamond, or salt, or sugar, or any one of the hundreds of thousands of such examples that arrangement is the basis both of structure and quality, but there is order also in such substances as fats and muscles, hair and wool, cotton and silk, bone and shell. We can already observe even in these bodies cases in which their properties depend on the order of the structure. We infer that the design always has its importance and that it must be studied if we wish to know how the properties of any solid body are related to its composition. The modern study of biochemistry has already made great progress in the establishment of the link between the two sciences from which its name is jointly derived, but the hyphen between the "bio" and the "chemistry" is really a very long one, and this new range of inquiry is part of it.

ORDERED SCATTERING OF RAYS.

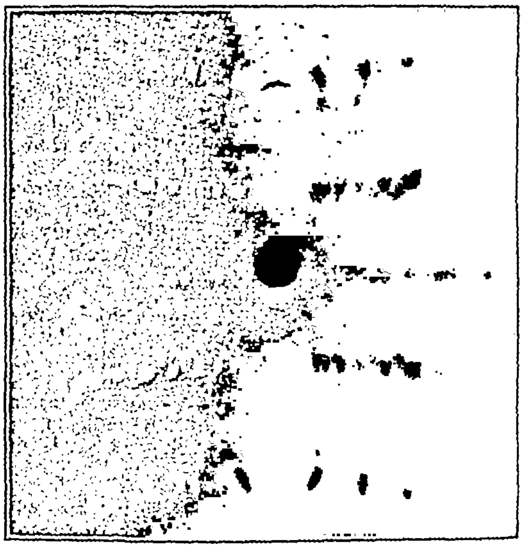
The second fact on which we have to depend is a phenomenon characteristic of radiations such as light or sound. When X rays, which may be described as a wave motion in the ether, pass through a body in which there is regularity of arrangement such as I have been describing, part of the radiation is scattered in a peculiar manner which is characteristic of the arrangement. The scattering does not take place all round; it is sharply confined to a limited number of possible directions. By examining those directions we can determine details of the design. If there is no regularity there is no choice of direction. This is a particular manifestation of the phenomenon of radiation of which I have just spoken. An example or two will serve to make the point clearer.

FIG. 1.



Mannitol.—X ray diagram obtained by Miss T. Marwick using the Laue method. A fine pencil of heterogeneous X rays passes through a small crystal, in this case mannitol, and strikes the photographic plate at the centre of the picture. The regular arrangement of spots is due to the X rays scattered by the crystal according to the principle explained in the text. The design of the crystal is to be deduced from the positions and intensities of the spots. This method of forming the photograph is due to Dr. Laue.

FIG. 2.



Asparagine.—X ray diagram, obtained by W. H. George using the "rotation" method. The X rays are monochromatic, and the crystal is rotated during the exposure. Asparagine is allied to aspartic acid (see the table of wool constituents given later). The network at the back of this diagram is placed there for convenience of interpretation.

We take first a very simple case. We strike a Burmese gong made of a single sheet of metal. It is a beautiful piece of the metal worker's art, and one of its special characteristics is that the sound rings on for a long time because, as a matter of fact, there is very little waste of energy in the material itself. But the characteristic which I would have you note is that you hear it strongly when its broadside is towards you, and only feebly when it is edgeways on. There is a choice of the directions in which the radiation spreads away. The gong is supposed to be struck at one corner, so that it turns rapidly about its cord of suspension, and the rapid alternation of intensity enforces the sound upon the ear. The cause of the choice of direction is the regularity of the timing of the two sources of sound; for there are two sources—namely, the two sides of the gong. Each side is sending out pulses into the air, and, of course, they are in time with each other; when the one is pushing the air away the other is drawing back so that the air follows it. The concentration of the emission of sound in some directions rather than in others is due to this conspiracy of the two emitting surfaces and the regularity of their joint action.

Here there are but two sources of sound and a very simple and rough delimitation of the directions in which the combined effect proceeds. Suppose now we consider a more complicated case. A number of straight lines are drawn parallel to each other, and equally spaced, upon a polished surface. A ray of light falls upon the surface. There is, of course, the ordinary reflection, but in addition feebler beams of light are scattered by the mirror and proceed in certain definite directions. If the lines were ruled anyhow this would not happen. Light would be scattered diffusely; but there would be no chosen direction. The surface of the mirror is now ruled into separate sections, each of which may be considered as a secondary source of light because it scatters part of the main beam, and, because of the regularity of the arrangement, the timing of the various sets of secondary waves is also regular. In the gong there were only two secondary sources which acted together; an optical grating of ordinary pattern contains many thousands. In both cases there is selection of direction, but whereas in the case of the gong the direction of maximum emission was ill-defined, the latter shows very sharply delimited secondary rays. The theory of the phenomenon is well known to the student of physics. There is no need to go into it now; all that has to be observed for our purpose is the fact of the existence of particular directions of radiation when there is regularity of arrangement among the sources of the secondary emission. It will readily be understood that observation of the particular choice of directions supplies information as to the ruling of the lines; in fact, when the lines are spaced widely, the special directions crowd closely in on the principal direction of reflection, and vice versa.

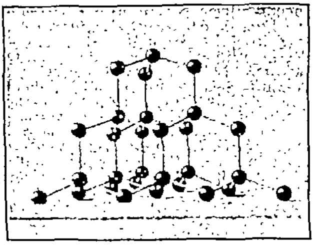
THE X RAY DIAGRAM.

It is now but one step to the X ray case. When the X rays pass through the crystal each electron scatters a minute fraction of the incident radiation; and because the electrons on the average, even after allowing for any periodic or other movements about their main position, show regularities in their arrangement consequent on the regularity of arrangement of the atoms to which they belong, therefore the X rays can be scattered in certain directions only. These directions are related to the arrangement or structure of the crystal, and photographs such as those of Figs. 1 and 2 really contain the full story of the crystal construction. This is the simple basis of the new method of analysis. Up to the present we have made such advances that the simpler patterns can generally be read, though the more difficult often baffle us. But the point to be noted is that the information is there in the photograph, and very precise information at that. The position of every spot has its meaning, and not only the position but also the intensity or magnitude of the spot. It would take far too much of my present allowance of time to show how the interpretation is accomplished; such matters must be left to the text-books of the subject of which many have already been written. I must confine myself mainly to results. One point, however, must be referred to. There is a special reason why this inquiry into the regularity of the crystal is the province of X rays, and not of visible light. The periodicities in the crystal are of the same order of magnitude as the wave-lengths of the X rays—some ten thousand times smaller than the length of light waves. If this were not so the whole business would fail.

APPLICATION TO ROCK STRUCTURE.

It was natural that the first application of the analysis when it appeared some 15 years ago should be made to the simpler and more obvious crystalline structures such as diamond, rocksalt, fluorspar, quartz, and many others. The whole series of the silicates which form the bulk of the earth's crust have lately been analysed, and their curious dependence on oxygen as the fundamental element of their structure has been laid bare. I shall, however, say very little of all these structures, as the substances with which we are now concerned are, broadly speaking, of a different class. The forces which bind the salts together are very patently *electrostatic*. When, *for example, sodium and chlorine* are in juxtaposition each sodium atom loses a negative electron and each chlorine atom gains one. Thus the sodium atoms become electrically positive and the chlorine negative. The rocksalt structure is broadly explained as due to the desire of each negative atom to surround itself with positives and vice versa. This design, which we sometimes call "ionic," is very common in inorganic substances. But in organic substances it is relatively rare.

FIG. 3.

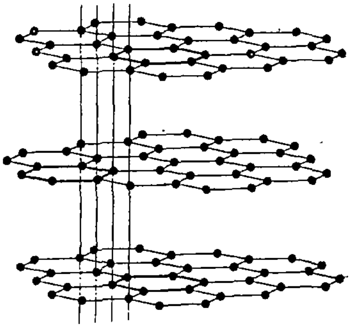


X ray analysis of the structure of diamond; every carbon atom lies at the centre of a tetrahedron at the corners of which lie other carbon atoms.

ORGANIC CRYSTALS.

I will proceed, then, to discuss certain crystals in which the design is more pertinent and typical. I must first take that of the diamond. The X ray analysis shows a very remarkable structure (Fig. 3). Every carbon atom—the diamond, of course, consists of carbon only—is surrounded by four others arranged about it in a tetrahedron, the centre of which it occupies itself. The distance from centre to centre of two neighbouring atoms is 1·54 Angstrom units; a hundred million Angstrom units are equal to one centimetre. The bonds between atom to atom are not the same as in rocksalt; there are here no positives and negatives. The bonds are of a different character altogether, and of far greater strength. When these are the forces that bind the atoms together into groups or molecules the combinations generally offer great resistance to disruption. A diamond may be looked on as one huge molecule of indefinite size and content. Its great hardness is a consequence of its structure. In a substance like naphthalene the ten carbon atoms which it contains are bound together by bonds similar to those found in diamond, and hence arises the stability of the molecule. But in solid naphthalene the molecules are held together by very much weaker bonds of a totally different character, and hence the molecules are easily separated; the substance has a low melting-point.

FIG. 4.



Structure of graphite: carbon atoms linked together in sheets.

Graphite also consists of carbon atoms, but its character is totally different; and we find the explanation when we learn its design. The atoms are now linked together in sheets, as if they lay at the points of wire netting of the ordinary hexagonal pattern (Fig 4). The distance from carbon to carbon is a very little less than in diamond. But the sheets, which are arranged like the leaves of a book, are separated from one another by no less than 3·40 Angstrom units. If we supposed that the carbon atom was a hard sphere having a diameter of one and a half Angstrom units, basing our assumption on the structure of diamond and on the arrangement of the atoms in the separate sheets of graphite, we should be at a loss to know what kept the sheets so far apart. But in fact we have no right to make suppositions of this kind. We do not know what keeps the sheets so far from one another any more than we know what sets the diamond distance at 1·54. We have to accept the fact whether we can give a reason for it or not. But we are not surprised to find that the forces binding sheet to sheet are far less than those that bind atom to atom in the same sheet. One sheet slides over another with the greatest ease; indeed, as we know, graphite is a very excellent lubricant.

In diamond the strong kind of bond holds the carbon atoms together in all three dimensions; in graphite it acts in two dimensions only, a weaker kind keeping the sheets together. We can imagine a third form of structure in which the strong bonds act only in one direction, thus forming strong chains of carbon atoms, while each chain is bound less firmly to other chains. And we find, in fact, that this arrangement is extremely common, especially among the substances that are used in the formation of living bodies.

STRUCTURE OF THE LONG CHAIN MOLECULES.

The simplest known form of such a chain consists of a zigzag of carbon atoms, the two atoms at either end being furnished with three hydrogens and every other with two. The X ray analysis has been applied with great success to these structures, especially by Dr. A. Muller and Dr. G. Shearer at the Royal Institution. It is found that each carbon atom is again at a distance of 1·5 Angstrom units from the next, from which we infer that the strong bond is in action, and that the peculiar zigzag form is such as could be carved out of the diamond. The slanting edges of the model in Fig. 1 show carbon atoms arranged in this zigzag form. The distance between a carbon atom and the next but one is 2·52 units. In fact, there is a strong though not complete likeness between the three structures. This particular form of chain is, of course, known as a paraffin. The regular periodicity of 2·52 Angstrom units along its length and the less perfect periodicity of 1·26 units are the regularities of arrangement which the X ray analysis at once reveals.

The chemist has shown us that these carbon chains are also to be found with many varieties of terminal. If we take away one of the three hydrogen atoms from one end and substitute an oxygen with a hydrogen attached to it we have an alcohol; if we take away the remaining two hydrogens and replace them by a single oxygen we have a "fatty acid." Changes may be made also on the sides of the chains; an oxygen may be attached in place of two hydrogens forming a so-called "ketone," and so forth. There is an immense number of different molecules, some long, some short, fringed and terminated in different ways, but always there is the backbone of the single line of carbon atoms, joined by the strong diamond bond. It is a strange thing that different plant products should have place in their constitutions for chains of characteristic length, as for instance palmitic acid, the fatty acid with 16 carbons, which is found in palm oil, valeric acid with five carbons in valerian root, and so on.

We are now, of course, approaching the range of structures found in living bodies; the long carbon chain is characteristic of all fats and oils.

CELLULOSE.

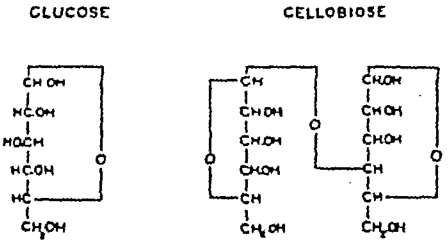
The initial successes of the X ray analysis in giving us the accurate geometry of some organic substances, and in particular the long chain compounds, has led to its tentative application in some difficult cases where an answer would be of great scientific or industrial value. It was natural that an early attempt should be made to investigate the structure of cellulose. The problem was especially difficult because the crystals of cellulose are so minute; the arrangement which X ray analysis depends on for its usefulness is present in the cellulose mass, but the mass consists not of one crystal, but an immense number of small crystals in disordered array. This adds greatly to the difficulties of the X ray technique. Moreover, the chemistry of cellulose had not, when the work began, been perfectly worked out; and it is a great help to the determination of structure if the composition of the molecule is first known. Nevertheless, the persistent attacks on the problem seem now to have attained success, at any rate as regards the more important features of the design. There may be modifications of detail yet to come. This work is largely due to H. Mark and his collaborators, first at the Kaiser Wilhelm Institut in Berlin and recently at the research laboratories of the I.G. Farbenindustrie Aktiengesellschaft at Ludwigshafen.

The solution of the cellulose problem is a step on the way to the more complicated cases of wool, hair, and muscle. Let me therefore sketch very briefly the present position of the cellulose investigations. In this I am following Mark's account, versions of which are to be found in various German journals, scientific and industrial.[1] Other cellulose workers, for example, K. Hess and his collaborators, are not in complete agreement as to the interpretation of the results so far obtained. But my present purpose is rather to show how the research is being pushed forward than to give a critical examination of the various methods of procedure.

GLUCOSE.

Mark assumes the structure of the glucose molecule as suggested by Prof. Haworth of the University of Birmingham. According to the conventions of chemistry it is expressed so:—

FIG. 5.



GLUCOSE CELLOBIOSE

The backbone of the molecule is the chain of six carbon atoms joined together by diamond bonds. The diagram shows a curious linking of the first atom of the chain to the fifth by way of a single oxygen. If we would picture to ourselves the actual arrangement in space of the atoms in the glucose molecule, we must imagine that the major portion of the carbon chain is bent round as to form, with the oxygen, a hexagonal ring. We are quite familiar with carbon chains which are bent round to form rings: the immensely important case is the six-membered ring of benzene. The enormous development of organic chemistry rests largely on the discovery of the benzene structure, and it is an essential portion of the chemical theory that the atoms of the ring are bound together by very strong bonds. It is not surprising, therefore, that X ray analysis of benzene derivatives has found a centre-to-centre distance in the ring which agrees very closely with the corresponding distance in diamond—viz., 1·5 A.U. (Angstrom Units). The centre-to-centre distance in the combination of carbon and oxygen can also be determined from the X ray investigation of various substances, such as calcite, where the oxygens and carbons are strongly tied together. It varies from 1·2 to 1·3. It is important to observe that centre-to-centre distances can be expected to be similar only under similar circumstances. When oxygens lie close together, as in the silicates, but are not tied together by bonds of the strong sort, they behave as comparatively large spheres having a diameter of 2·7 A.U. My son and his colleagues at Manchester have shown that these large oxygen atoms are packed tightly together to form the bulk of the earth's crust, being held together by the relatively smaller atoms of silicon, aluminium, magnesium, and others.

In the glucose ring we should expect the oxygen atom to behave as a smaller atom, as it does in substances where it is equally tightly bound. The glucose ring, according to the diagram of Fig. 6, must have much the same dimensions as the benzene ring.

Two glucose molecules combine, according to Haworth, to form one molecule of cellobiose, in a manner represented by the formula. The join is effected between the first carbon atom of one ring and the fourth of the other. One oxygen and hydrogen pair, a so-called hydroxyl group, on each of these atoms is broken up; two hydrogens and one oxygen are removed, forming a molecule of water, and the remaining oxygen is the link between the two chains.

---

[1] For example, Die Struktur der Zellulose und ihre technische Auswirkung, Melliand Textilberichte, Heidelberg, 1929, Nr. 9; or Über den Bau des Krystallisierten Anteils der Cellulose II., Zeit. Phys. Chem., Abt. B, Bd. 2, Heft 1–2.

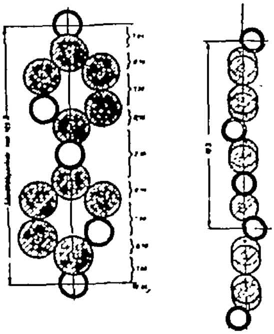
We may represent this by the model shown in Fig. 6 which is due to Mark, the dimensions of the model being in accord with previous X ray work on other substances.

In exactly the same way other glucose molecules may be connected up with the cellulose pair, and in fact a long chain may be formed resembling the simple carbon chain in the existence of strong linkages all along the line, though the links themselves are more complicated. The dimensions of the structure are shown in the diagram; there is a perfect periodicity of 10·3 A.U. along the line, and an imperfect periodicity of half that amount. Any one ring can be made to coincide with its neighbour by moving it 5·15 A.U. along the line and turning it round the line through 180°. There is, in crystallographic language, a screw axis.

This structure, we must remember, is arrived at by combining Haworth's chemical determination with the results of X ray measurements on the diamond and other crystals. The next step is to bring the X ray analysis to bear on the structure itself.

An X ray diagram is not so easily obtained from cellulose as from a substance more simple in its crystallisation, but careful technique has finally given results which are sufficient for the test of the supposed structure. It is found that agreement is excellent. The X ray diagram of a substance built of cellulose—e.g., ramie fibre, shows a perfect periodicity of 10·3 A.U., an imperfect periodicity of half that amount, and a screw axis. There is, therefore, good reason to suppose that the structure of Fig. 6 is actually existent in cellulose.

FIG. 6.



Model of cellobiose.—Shaded circles represent carbon atoms; oxygen atoms are drawn as double rings to show the limits between which their diameters probably lie. This model, due to Mark, shows two glucose rings, stripped of atoms unessential for the purpose of showing the method of combination, and joined together by an oxygen to form the kernel of the cellobiose molecule. Two views of the model are shown. It should be compared with the diagram of Fig. 5.

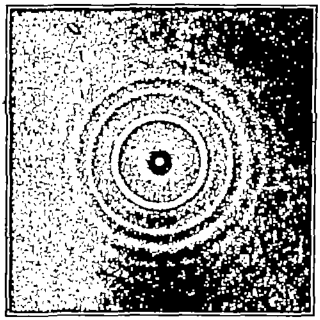
CHAINS TO CRYSTALS.

But the picture is not yet complete. In what way do these long chains combine to form the minute crystals? If we go back to the simple carbon chains we find them arranging themselves side by side, like cornstalks in a field; a sheet is formed in which the long molecules lie transverse to the sheet. The whole crystal is formed of many such layers lying on one another like the leaves of a book, as we found in graphite. Usually a mass of such a substance as stearic acid consists of a multitude of little crystals formed in this same way, the separate crystals lying in disorder with respect to one another. A single crystal, or perhaps one should say a mass of crystals nearly aligned to one another, is not easy to find, but, when found, is of great assistance to analysis. Good single crystals of stearic acid have actually been obtained and examined, so that the structure is well known. The chains of stearic acid are all of the same length and the layering is perfect. I ought to add that it is when we have such combinations of chains into single crystals that the X ray effects are most observable and valuable.

We are led to expect something of the same kind in cellulose, and it is actually found to exist. Cellulose chains do lie side by side in little bundles. The X ray diagrams tell us that there are periodicities not only along the chain but also in the side-by-side arrangement of the chains. The diagram of Fig. 6 shows the design of the structure and the dimensions as given by Mark.

It is possible to go one step further, and to find in the X ray diagram some information as to the size of the bundles in which these regular chains are arranged in regular fashion. This is done with the help of a certain principle of optics. If the spots in the diagram are sharply defined the minute crystals must be big enough to contain thousands of molecules, but when the number is small the spots are diffuse. From the appearance of the spots Mark deduces that there may be twenty to fifty links in each chain and that some dozens of chains go to the making of a bundle. The bundle corresponds to what has been called a "micell." Our picture is now fairly complete. The atoms form the glucose rings; the rings are linked together by strong bonds into a chain; the chains are drawn together side by side by much weaker forces; and a bundle of chains forms a micell.

FIG. 7.



Cystine.—This kind of diagram, due to W. T. Astbury, is typical of a substance consisting of a multitude of very small crystals, not arranged with respect to each other.

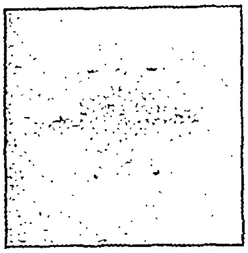
If a fibre is thus composed we should expect that when it is stretched the bundles are brought more or less into line. The X ray diagram shows at once that this is the case. When a fine pencil of X rays is passed through a specimen in which the crystalline bundles lie anyhow, rings are formed upon the photographic plate, as in Fig. 7, but when the fibre is stretched in a direction at right angles to the X ray pencil the direction of stretching must be somehow reflected in the picture, and indeed we find the rings drawing themselves together into spots along their circumferences until finally we obtain a diagram of spots approaching to the effect shown in Fig. 2, which it will be remembered is due to a single crystal.

STRETCHING OF FIBRES.

When a stretching force is gradually applied to a fibre there is, for small forces, a complete recovery as soon as the stress is removed. The small bundles are being pulled into alignment, but not so as to break any attachments. As the force increases some of the attachments are broken, but the bundles now get the benefit of lying more nearly parallel to one another and so of being in better position to exert their sideways attachments; in this way the increasing stress is resisted. But when all has been done that can be done in this way, a still larger stretching force will cause the bundles to slide past one another like threads that have been dipped in some sticky fluid. The substance *flows* and finally breaks.

It is clear that to pull a bundle in two would require the breaking of the strong bonds in the separate chains; if this marked the limit of the strength of the fibre it would, as Mark has pointed out, be many times as strong as steel. And why not? The links between atom and atom in a diamond are usually much more difficult to break than those between the atoms of a metal. A fibre breaks for a different reason—namely, that the side attachments of the chain and bundles are not able to prevent the chains from sliding past one another. It is strange to think that the spinning of a thread, which is designed to place the fibres in such a way that they resist being drawn past each other, is exactly what is done on an exceedingly minute scale in the structure of the fibre itself.

FIG. 8.



X ray diagram of mercerised cellulose.—This diagram, due to R. Andress, is similar in character to that of Fig. 2; it has comparatively few spots because the cellulose material does not present the simple problem of the single crystal. If it is examined carefully it will be observed that many of the spots are drawn out horizontally, but not vertically. The interpretation is that during mercerisation the long chains are pushed away from one another by varying amounts because foreign molecules wedge them apart. The chains themselves are not broken.

It would take too long to describe how on this point of view the effect of wetting alters the strength of a fibre; how the mercerisation of cotton pushes the chains apart without altering their length (see Fig. 8); why it was difficult in the first manufacture of artificial silk to avoid unevenness in gloss and in receptivity to dyes, and many other more or less complete explanations of industrial problems.

Let me now proceed to consider what has been done towards the application of the X ray methods to animal substances. Cellulose occurs in animal as well as vegetable structures, and is found to have the same form in both. Leaving this on one side we come to a vast range of substances which make up the living body, and if the X rays can show anything at all we are obviously in front of a series of very interesting researches.

HAIR AND WOOL.

Just as the X ray examination of cellulose has been pressed forward in order to obtain a better understanding of the properties of cotton and artificial silk, so also, in the interests of the textile industries, it has been applied to the study of hair and wool. The problem is far more difficult because the animal fibres are complicated mixtures of many constituents. Below is a list of the substances obtained from the hydrolysis of wool; I owe it to Mr. W. T. Astbury, of the Textile Research Department of the University of Leeds.

The complexity of this list shows at once why the work with wool is not so far forward as in the case of cellulose. Enough has been done, however, to show that apart from characteristic differences there is a great similarity in the general behaviour and construction of the two.

To begin with we have the well-known fact that the behaviour of the two classes of fibre under stretching forces are very much alike. There is the same reversible effect for small forces, and the same region of irreversible effect for larger forces. The effect of moisture and of heat are in the main parallel. It is true that wool has a greater power of recovery, and that wetting has a peculiar power of facilitating recovery, as if water could act as a lubricator, removing certain frictional effects and allowing the restorative forces to act. But such differences may readily be ascribed to the known differences in composition. If the physical properties of cotton are explicable on the hypothesis of micells composed of long chain molecules, it would be difficult to ascribe the behaviour of wool to some entirely different mechanism.

But apart from this general conclusion, the X ray evidence argues strongly in the same direction. It is possible to obtain X ray photographs with single fibres of hair and wool, and these show the same characteristics as cellulose. There are obviously small bundles of arranged molecules. Sometimes the bundles may show much disorder of arrangement, but in general the stretching of the fibre is accompanied by changes in the photograph which show an increasing alignment. Some of the spots on the photographs become very clear as the tension is increased, and Astbury finds that these indicate a size for the unit of pattern which has also been found in natural silk. This may possibly be due to the fact that two of the amino-acids of the table—viz., alanine and glycine—are found in silk also. The fine X ray photograph of cystine which Mr. Astbury has sent me contains three lines which agree with those found in wool. In general, the X ray photographs show just the same sort of changes where wool is stretched, or wetted, or chemically treated as appear in the cellulose photographs, allowing for the greater complexity of the case. Clearly there is an immense amount of work yet to be done before each of the wool constituents can be examined as to its structure, but there can be no doubt that in general there must be the same kind of arrangement in wool as in cotton. And what is found in wool and hair will surely be found in nerve and muscle.

A COMMON PRINCIPLE.

The suggestion forces itself on the mind that one and the same principle is in constant use by Nature to form living tissues which have strength and resilience, which may also be overstrained and finally broken. The adjustment of the means employed is a very striking feature of the scheme. Along the molecular chain strong bonds, of the same class as those that make the diamond, hold the links together and give the chain comparative permanency; lesser forces bind the chains into ordered bundles or micells and the micells into the general mass. I think we may justly say that we have now in our hands a method of analysis which has not only confirmed previous results in a novel manner but has opened up new ways for the study of living matter.

THE ÆTIOLOGY AND PROPHYLAXIS OF POST-ANÆSTHETIC SICKNESS.*

BY J. ROSS MACKENZIE, M.D. ABERD.,
LECTURER ON ANÆSTHETICS, UNIVERSITY OF ABERDEEN; ANÆSTHETIST, ROYAL HOSPITAL FOR SICK CHILDREN, AND ROYAL INFIRMARY, ABERDEEN.

EVERY anæsthetist must be conscious of the rapid progress which surgery has made in recent years. It is true that anæsthetics made modern surgery possible, but surgical technique to-day has outstripped anæsthetic technique and, it seems to me, threatens to leave our specialty behind.

Some of the delay in post-operative convalescence and a percentage of post-operative mortality might quite properly be assigned to the after-effects of the anæsthetic and its administration, and modern surgeons at home and abroad are turning to local and regional methods of anæsthesia in an endeavour to avoid the evil after-effects of general anæsthesia upon the patient. The clamant demand of surgery is for an anæsthesia which will at least not militate against the post-operative convalescence or recovery of the patient. It is obvious that if the status of the anæsthetist is to be raised and the importance of anæsthetics recognised by the surgical world and the public, then the anæsthetist must accept a larger share of responsibility for the surgical patient both before and after anæsthesia.

Vomiting.

The chief factors involved in the act of vomiting are: (1) violent contraction of the diaphragm and of the muscles of the abdominal wall; (2) violent contraction of the muscular fibres of the stomach with relaxation of the cardiac sphincter; and (3) reversed peristalsis in the small intestine, giving rise to relaxation of the pyloric sphincter and the passage of bile and intestinal contents into the stomach.

The vagus, phrenic, and spinal nerves as well as the sympathetic are intimately concerned in the act of vomiting. In retching the same parts come into play, except that the cardiac sphincter does not relax and there is no violent contraction of the muscular coats of the stomach.[1 2 3] Nausea is the sensation of sickness which precedes the act of vomiting. It is caused by an increased tension in some part of the alimentary tract; if this tension increases to the extent of producing pain, the nausea culminates in vomiting.

Post-anæsthetic sickness and retching occur as the result of irritation of the vomiting centre in the medulla by stimuli from three main sources: (1) the direct action upon the vomiting centre of toxins circulating in the blood stream; (2) the indirect action of reflex stimuli which reach the vomiting centre through afferent nerve-fibres in the stomach, intestine, peritoneum, bronchi, and special senses, and those set up by pathological conditions in the patient; and (3) the influence of the higher brain upon the vomiting centre. This last varies widely in individual cases and is very difficult to estimate, but evidence is accumulating to show that the faculties of emotion, imagination, anxiety, and reason may create such a disturbance during the pre-anæsthetic period as to excite active sickness in the post-anæsthetic period.

Even the mild type of post-anæsthetic sickness is of the highest importance to the patient, the surgeon, and the anæsthetist for the following reasons:—

(a) It is a source of much post-operative discomfort, misery, and distress to a considerable percentage of patients, especially after abdominal operations.

(b) In the mind of the patient it is frequently the most serious objection to any future surgical interference.

(c) It frequently prolongs convalescence and may actually turn the balance against recovery. There is little doubt that vomiting is an important element in the production of post-operative adhesions and hernia. These are usually difficult cases both to the anæsthetist and the surgeon.[4] The peritoneum may have been difficult to close and, as the result of some such effort as vomiting, a piece of omentum bulges through, ultimately forming a ventral hernia or, with further effort, a rupture of the abdominal wound.

(d) It is a familiar sequela of every anæsthetic agent, even gas-and-oxygen, and may follow any method of administration: endotracheal, colonic, spinal, and local infiltration.

(e) It is a standing reproach to anæsthetics and the anæsthetist, and not less to surgery and the surgeon. The subject has not received from any member of the surgical team the attention it deserves, and as a consequence our knowledge of how to recognise, in the individual case, the factors which predispose to post-anæsthetic sickness is very circumscribed, while our treatment is empirical and largely devoted to curative rather than to preventive measures.

In my experience there are four outstanding predisposing factors to post-anæsthetic sickness—namely, the psychic element in the patient, the preoperative preparation, the anæsthetic agent and its administration, and surgical trauma.

The Psychology of the Patient.

The influence of the phenomena of the mind is present throughout the conscious, subconscious, and unconscious state of anæsthesia, and the personal peculiarities of physical and mental organisation known as temperament—in the one case phlegmatic and in the other emotional—dominates, in many patients, the whole pre-anæsthetic, anæsthetic, and post-anæsthetic period.

1. *The Pre-anæsthetic Period.*—It has been stated that "dread of the anæsthetic is the arch-enemy of the anæsthetist,"[5] but much more is it the arch-enemy of the patient. The effect of apprehension, fear, dread, or anxiety regarding the operation or the anæsthetic, and their success or failure, is underestimated. Much will depend upon whether the particular emotion has been expressed or repressed during the pre-anæsthetic stage.[6] If the former, it may be confidently expected that the post-anæsthetic effects will be reduced to a minimum, whereas in the latter they are usually increased to a maximum. The unusual environment of the hospital or nursing home disturbs the patient's mental equanimity in no ordinary degree. This emotional state engenders anorexia, with much diminished carbohydrate consumption. It inhibits the secretory function of the gastro-intestinal tract and its concomitant glands and impairs digestion, assimilation, and motility.

Glycosuria is not uncommon in the pre-anæsthetic period. It may be first detected on the morning of the operation. If the urine contained no sugar on previous examinations it may be taken that the sudden appearance of glycosuria is due to pre-anæsthetic emotional metabolic disturbance. It is held by psychologists and physiologists that the primary cause is an emotional stimulation of the suprarenal glands with an excessive secretion of epinephrine[7 8] which, on the one hand, depresses the gastro-intestinal function and, on the other, excites an abnormal breaking down of liver glycogen with resulting hyperglycæmia and glycosuria.

Pain—acute, continuous, or recurrent—controls in a remarkable degree the psychic element in the surgical patient. It appears to increase the safety and simplicity of general anæsthesia and to modify the after-effects.

This explains why obstetric patients are anæsthetised so easily and recover so well. In the surgical patient anxiety arises partly from fear that the surgeon may commence the operation before they are properly asleep or that they may not wake out of the anæsthetic, and partly from dread of what may be found at the operation or that they may not recover. This mental agony may have continued for several days. In obstetrics and to some degree in emergency surgery the opposite condition prevails. Here the anxiety is to get an anæsthetic to relieve the pain; the patient is confident not only that she will waken but that when she does her pain and trouble will have disappeared.

---

* Being the presidential address to the Scottish Society of Anæsthetists on Oct. 26th, 1920.

2. *The Anæsthetic Period.*—The ordeal to a patient of entering an anæsthetic room and meeting there for the first time the anæsthetist—a person about whom the patient was not consulted, probably never saw before, and whose name conveys nothing—has to be experienced to be understood. From the practical, humane, and economic point of view there can be no doubt that a visit from the anæsthetist on the day preceding the operation, the examination and assurance that all is well for the anæsthetic, a friendly greeting when the patient arrives in the anæsthetic room, and a word of encouragement as he halts on the brink of oblivion do much to create and maintain the anæsthetic equanimity so essential to the well-being of the patient before, during, and after operation.

The sensation of tension in the head or of suffocation or of strangulation which may occur in the early stage of the induction is a very real and dramatic one. It gives actual form to the emotional apprehensions of the pre-anæsthetic stage and creates the mental impression of impending disaster. The climax is reached in the second stage of the induction when acute brain-storms break over the patient. These are expressed in sudden excitement, active resistance, and rigidity followed by depression and exhaustion of the vital medullary centres. Is it surprising that the psychologist is interested to known what the post-anæsthetic effects of these profound impressions are and whether there are any prophylactic measures which might reasonably be taken to protect the patient?

For practical purposes the conscious mind, the sensation of pain, and the cortical reflexes are out of action during surgical anæsthesia. On the other hand, it appears that the subconscious and unconscious mind of a patient under surgical anæsthesia may be abnormally active and alert. I have frequently noted that in the course of even a short anæsthetic, years of personal history, long forgotten or recent, pleasant or otherwise, may be reviewed by the patient, with corresponding consequences in the returning consciousness. The normal control of the spinal reflex by the upper neuron is in abeyance during the early stage of surgical anæsthesia, and the knee-jerk and ankle-clonus are both exaggerated. Ether tremor arises in the same way and all three disappear in deep surgical anæsthesia, to become exaggerated again in the early recovery stage of anæsthesia. In surgical anæsthesia the optic thalamus forms an important subcortical station for the reception of sensory stimuli, especially those of pain and visceral sensation. The shrugging of the shoulder —usually the left—the local muscular rigidity which frequently occurs in exploration of the upper abdomen, and the moaning and sobbing which may accompany exploration of the female pelvis arise from local sensory stimuli which reach the optic thalamus and produce a passive protest against indelicate handling of the abdominal or pelvic contents.

These points have been emphasised to show that processes of nerve excitement and exhaustion, begun in the pre-anæsthetic period, may continue and gain force throughout surgical anæsthesia and cause profound disturbance to convalescence.

3. *The Post-anæsthetic Period.*—Sickness and vomiting often occur in the subconscious stage of the return journey from unconsciousness in anæsthesia. Every anæsthetist is familiar with the clinical picture of approaching sickness upon the table. This subconscious vomiting is probably due either to the awareness by the cortical brain cells of stimuli which reach them from the operation area or to the lesser influence of the anæsthetic on the medullary centres. The patient has no consciousness or memory of this vomiting on the table.

Local infiltration of the operation area with ¼ per cent. or ½ per cent. novocaine appears to protect the patient against stimuli reaching the vomiting centre, even when the ocular reflexes have returned. I have often observed in the process of de-etherisation that patients who have had novocain show clinical signs of approaching sickness much less frequently than those who have had no infiltration analgesia. The more rapidly the patient is de-etherised the more likely is retching or vomiting to occur upon the table and to discontinue thereafter.

Much more frequently vomiting occurs first in the conscious stage of the recovery from anæsthesia and recurs at intervals during 12–24 hours. Children are less liable to post-anæsthetic sickness than adults, and infants less than children. Several factors may account for this. In infants and children the preparation for anæsthesia is much less an interference with Nature, the condition demanding surgical intervention is more often the only pathological process at work, and the psychic disturbance during the pre-anæsthetic period is much less pronounced, since emotion, imagination, and anxiety are immature. Gas-and-oxygen is much more often the anæsthetic of choice, and the duration of the anæsthesia and the surgical trauma are on an average less than in adults. Probably the most important factor is that in infants and children the central nervous system is less specialised, and the higher brain neither receives nor redirects afferent stimuli to the same degree as in adults. Animals rarely suffer from post-anæsthetic sickness, irrespective of the anæsthetic agent or the duration of the anæsthesia (Table I.).

TABLE I.—*Sickness in 500 Cases.*

Preoperative Preparation.

In the preparation of the surgical patient there is a misdirected zeal which dies hard. The nearer the patient can be brought to or allowed to remain in the normal standard of physiological efficiency, the easier and less interrupted will the convalescence be. One of the surest methods of reducing a patient's vitality and resistance to infective processes is to subject him to purgation, enemata, and starvation. It is the proverbial burning of the candle at both ends.*

Purgation.—In recent years our views regarding preoperative aperients have undergone considerable change, but in my estimation they are still drastic and require further modification. If the patient has had a regular daily stool, then the less the normal is disturbed the better, both upon the operation table and during convalescence. There is no objection to a mild aperient such as cascara, compound liquorice, or milk of magnesia 48 hours before operation, but any complete or watery evacuation of the gastro-intestinal tract, such as results from castor oil or sulphate of magnesium, promotes conditions which tend to handicap the patient, the surgeon, and the anæsthetist; more especially if the aperient is given, as so often happens, 12 hours before operation. A drastic aperient given to a patient in the unusual surroundings of the hospital or the nursing home not only disturbs and actually interrupts the rest and sleep so essential to normal physical vitality, but agitates the mind and dissipates the nerve energy which should be conserved for what may be the ordeal of his or her life. It irritates the mucous membrane of the intestinal tract and renders it red and swollen, while the gut may be empty and collapsed or distended with gas, the worst possible conditions for surgical intervention and technique. Further, it depletes the body of essential fluid containing chlorides. It hurries partially digested food along the intestinal tract, producing fermentation, tympanites, abdominal distension, and much discomfort. It produces excessive peristalsis, exhausts the muscular coats of the intestine, and is a fruitful cause of paralytic ileus.

Enemata.—There is no part of the preoperative preparation which more disturbs the psychic balance of the patient than the time-honoured enema, which often seems to be considered the necessary complement to drastic and complete evacuation of the gastro-intestinal tract. By the majority of patients the *enema is anticipated with dread, borne with patience* and courage, and remembered with apprehension. An enema on the morning of the operation not only curtails the patient's rest and sleep but stimulates and exhausts the lower bowel. Apart from rectal cases, it is difficult to follow the rationale of this measure in the routine preparation of surgical cases, *and I am of opinion that except in special cases it is* definitely detrimental to the best interests of the patient.

Has the surgeon any views upon the matter, or has the anæsthetist? If so, why is such an important item in the preoperative preparation of the patient left largely to the discretion of the nursing staff? *My own view*, as an anæsthetist, is that drastic evacuation of the gastro-intestinal tract and irritating enemata not only reduce the surgical patient's physical and nervous vitality and thus delay convalescence, but are potent factors in the causation of post-anæsthetic nausea, vomiting, tympanites, and paralytic ileus.

Starvation.—Any considerable modification of the preoperative diet or nutrition of the patient, such as tends to produce inanition or disturb metabolism, is highly detrimental to post-anæsthetic convalescence. The inanition may arise in several ways. It frequently happens that food has been withheld or that there is no appetite, or that the food is taken and promptly ejected, or that the power of digestion and assimilation is temporarily altered. There is no question about the power of the mind over the processes of digestion and absorption, and even the suggestion of an anæsthetic or of an operation is sufficient in some people to produce anorexia, immotility of the alimentary tract, and defective digestion of its contents.

I am convinced that in many cases too little time is spent by the nursing staff in attempting to coax or persuade the surgical patient to take food. It may not be good manners but it is certainly good policy, for food is the agent which produces normal gastro-intestinal peristalsis; it should be given in abundance and in an easily digested, semi-solid form right up to within a few hours of the time of operation. Carbohydrates have a much greater preoperative and post-operative food value than proteins, and yet the cup of beef-tea or bovril is offered when a teaspoonful of glucose or a cup of weak tea with plenty of sugar would do infinitely more good. The absorption of carbohydrate commences almost as soon as it is taken, and it has been shown that the amount of sugar absorbed per hour is constant for four hours if a sufficient quantity has been given.[10]

One of the conditions which definitely alters the absorption of carbohydrate is starvation. The coefficient of absorption of carbohydrate after 24 hours' starvation was found experimentally to be 0·266 g. per 100 g. of body-weight per hour, whereas after 48 hours' starvation this figure was reduced to 0·178 g. per 100 g. of body-weight per hour.

Any deficiency of carbohydrate in the diet rapidly causes a diminution of the glycogen stored in the liver. It appears that this depletion of the liver glycogen is but a temporary phase and that the glycogen content rapidly increases and remains more or less constant throughout the period of carbohydrate deficiency. The loss of liver glycogen is presumably made good from the storage of glycogen in the muscles and from the *protein of the tissues.* It is at this stage and in this way that the general metabolism of the surgical patient is first disturbed. The complete oxidation of fat depends upon the normal carbohydrate content of the blood and tissues. As a result of the incomplete oxidation of fat, oxybutyric and diacetic acids are produced with acetone as a by-product. Any degree of ketosis is generally recognised as an exciting factor of post-anæsthetic sickness.

Many surgical patients appear to be the potential victims of a vicious circle before they reach the operation table: (1) starvation and purgation producing hypoglycæmia; (2) hypoglycæmia causing incom*plete oxidation of fat*; (3) the products of incomplete oxidation of fat causing ketosis; (4) ketosis possibly causing post-anæsthetic sickness; (5) vomiting producing hypoglycæmia.

The Anæsthetic Agent.

The anæsthetic agent has too long been made the *scapegoat of post-anæsthetic sickness, whereas it is* at most only an isolated factor in the ætiology, and in many cases has no responsibility. There are patients who tend to have post-anæsthetic sickness irrespective of the agent used to produce anæsthesia. They belong to the highly emotional type whose endeavours are concentrated upon concealing their dread and apprehension of *the operation* and the anæsthetic and who volubly express their complete indifference to both. Bitter experience has taught me to regard their repressed emotion with suspicion; in the language of Shakespeare, "methinks the lady doth protest too much." Here is the record of such a patient.

A female, aged 50, was to have perineal repair and hysteropexy done in two stages. Every precaution was taken in her preparation. She indulged in loud laughter, and emphatically asserted that she was pleased to have her anæsthetic and operation. It was an easy gas-and-oxygen anæsthesia with a trace of ether, but she was actively sick for three days. Two weeks later the hysteropexy was done. Increased precautions were taken against a repetition of the sickness and the patient expressed, with much laughter but no tears, that she had neither dread nor fear of the anæsthetic or the operation. Gas-and-oxygen plus ether was given and as on the previous occasion she was very sick for two days. Examination of the urine, vomit, and blood gave no clue to the ætiology, and I was forced to the conclusion that this was a case of repressed emotion irritating the medullary centres and producing post-anæsthetic sickness.

There is another type of patient who suffers post-anæsthetic sickness with local infiltration or regional analgesia but not with a general anæsthetic. This type has a dread of being awake during the operation, and the nerve tissue suffers immeasurably more irritation with local or spinal than with a general anæsthetic (Table II.).

TABLE II.—*Anæsthetic Agents and Method of Administration.*

250 children.	E.	Ethyl chloride+E.	N_2O+O_2 +E. Bag.	N_2O+O_2 +E. Endotracheal.	N_2O+O_2. Bag.
	Open or perhalation.				
No. of cases	25	20	145	30	30
No. sick ..	10	10	15	2	3

250 adults.	E.	Ethyl chloride+E. Perhalation.	N_2O+O_2 +E. Bag.	N_2O+O_2 +E. Endotracheal.	N_2O+O_2. Bag.
No. of cases	50	100	50	40	10
No. sick ..	45	92	23	10	5

In general hospital anæsthetic practice the agents most frequently used are ether (open, perhalation, closed, colonic, or endotracheal), or ethyl chloride and ether, chloroform, gas and oxygen with or without ether, local infiltration of novocain, or spinal analgesia. The largest percentage of post-anæsthetic sickness occurs after some form of ether anæsthesia. There are various ways in which the anæsthetic agent may predispose the patient to sickness, and the particular system through which the vomiting centre is stimulated is largely determined by the susceptibility of the individual. In one case it may be by the direct toxic action of the anæsthetic agent carried by the blood stream to the vomiting centre in the medulla. In another it may be by afferent stimuli which reach the vomiting centre through nerve-endings in the stomach and bronchi or the organs of taste and smell.

Evidence is accumulating that in all cases of general anæsthesia the quantity and quality of the internal secretions of such organs as the suprarenals, the pituitary, the liver, the pancreas, and the thyroid are much disturbed before, during, and after the administration.[11 12] For example, an ether anæsthesia stimulates the suprarenal glands and they secrete an excess of epinephrine which stimulates the breaking down of the glycogen in the liver, resulting in a hyperglycæmia which may overcome the renal threshold and cause glycosuria. In a series of estimations of the blood-sugar before, during, and after ether anæsthesia I found that it gradually rose from the normal level, 0·1 per cent., to 0·2 per cent. and even 0·25 per cent., and remained at this high level throughout the administration. There was no evidence of any reduction of the percentage of blood-sugar during prolonged anæsthesia and it only very slowly came back to normal on cessation of the anæsthetic. It has been demonstrated by experiment on animals that the injection of adrenalin will produce hyperglycæmia and that the hypoglycæmia which arises from the injection of insulin, when the carbohydrate in the blood and tissues is deficient, can be modified or actually counteracted by the administration of adrenalin.

Further, it is claimed that the secretions of the pituitary and thyroid glands play an important part in the metabolism of carbohydrate and that the danger of hypoglycæmia following upon injection of insulin is much diminished if a dose of pituitrin is given along with or immediately following the insulin. This partly explains the benefit to the patient from repeated small doses of pituitrin or adrenalin after an operation. Thus, as the result of ether anæsthesia the suprarenals are stimulated and liver glycogen is broken down in excess, resulting in hyperglycæmia, followed in the post-anæsthetic period by exhaustion of residual epinephrine and depleted body glycogen, with a potential hypoglycæmia and ketosis in each case.

The influence of morphia as a factor in post-anæsthetic sickness depends upon the susceptibility of the individual patient, and my experience in the great majority of cases is that the evil effects of preliminary morphia are far outweighed by the measure of repose, well-being, and indifference with which the patient arrives in the anæsthetic room. The duration and depth of anæsthesia have an important bearing upon post-anæsthetic sickness, and closely allied is the dangerous factor of incipient anoxæmia.

Surgical Trauma.

There are surgeons whose dexterity and gentleness in handling tissues is such that it almost appears of small consequence what anæsthetic agent is used, for their patients are already in a fair way to an easy and rapid convalescence. From the anæsthetist's point of view the surgeon who pushes his fist through a small opening in the peritoneum and sweeps from liver to spleen and forthwith digs into the pelvis, is doing incalculable damage, from which the patient will suffer in the post-anæsthetic period. It is here that the surgeon and anæsthetist, working in complete harmony and with one aim in view—namely, the conservation of every particle of energy, physical and nervous, can perform prolonged and difficult operations with the minimum of evil effects.

Prophylactic Treatment.

At the present moment there is no preventive treatment known that will protect every surgical case against post-anæsthetic sickness. The ætiological factors at work are so diverse that only by the study of the individual case can we hope to make any progress in this important subject.

Let me indicate the lines along which, it appears to me, the anæsthetist ought to work.

1. The surgical patient should come under the preanæsthetic supervision of the anæsthetist at the earliest moment after reaching the hospital or nursing home and should remain under his supervision until the danger of post-anæsthetic sequelæ has passed.

2. Purgation and enemata should only be done by the express instructions of the surgeon and in ordinary cases never within 48 hours of the operation.

3. Starvation should not include more than one meal before operation. It is very important to maintain a high glycogen content of the liver and muscles; to accomplish this not only should food rich in carbohydrate be continued until within a few hours of operation, but it should be given at the earliest possible moment after, in the form of orange juice, sweetened water or tea, or glucose with pancreatin. It is essential that the patient be encouraged in this course.

4. Insulin was hailed as a specific against post-anæsthetic sickness,[13–16] but it was soon realised that insulin in the absence of a sufficiency of carbohydrate was a dangerous agent. It is not easy to be sure of the absorption and oxidation of carbohydrate[17] when given per rectum, and I doubt whether there is any justification for giving insulin in routine cases except in conjunction with intravenous glucose saline.

5. Stomach lavage before and after the anæsthetic is a procedure which in my experience has considerable merit and deserves to be more extensively practised. Normal saline solution with 10–20 per cent. glucose is excellent for the purpose, and a few ounces of the fluid should be left in the stomach after each lavage.

6. Intravenous hypertonic saline solution has been used after critical operations, in many cases with most brilliant results, including the absence of any post-anæsthetic sickness.

7. In order to combat any tendency to acidosis or depletion of the alkaline reserve it has been customary for anæsthetists and surgeons to prescribe alkaline fluids. From recent experimental work by Haldane[18] and Goldblatt[19] it appears that the ingestion of sodium bicarbonate in such amount as is likely to produce any degree of alkalosis is fraught with the danger of causing ketosis. Goldblatt has shown in rats that the ingestion of sodium bicarbonate not only hinders the metabolism of carbohydrates and the deposition of glycogen in the liver and muscles but that it prevents complete oxidation of fat with resulting acetonuria.

8. The anæsthetist ought to make an accurate estimate of the surgical risk involved, both immediate and remote. Such an examination makes the pleasant impression upon the patient that every precaution is being taken for his safety and comfort. It is important that the anæsthetist should conduct himself during his visits with a quiet optimism and thus engender in the patient assurance, equanimity of mind, appetite, and sleep.

9. The anæsthetic should be chosen with due consideration for the patient, the surgeon, and the duration of the operation. The chief point regarding the anæsthetic, after the agent and the method of administration have been decided, is that the minimum which will produce efficient anæsthesia should be used throughout the operation. Anæsthetists tend to forget that the ideal in anæsthesia is not how deep with safety to the patient, but how light with efficiency to the surgeon.

10. Anoxæmia should be carefully avoided throughout the operation by supplying oxygen, and de-etherisation practised by hyperventilation with carbon

dioxide.[20] This procedure corrects and maintains the acid-base balance of the blood and restores tone and peristalsis to the gastro-intestinal tract.

11. The patient should be assured of a restful night before operation by means of veronal or bromidia, and should not on any account be disturbed.

12. Dr. Joseph Blomfield[21] recommends glucose ℥i., aspirin grs. xx., bromide of potassium ʒi., in half a pint of water per rectum as soon as the patient returns to bed, and I have found this very valuable. I have used small doses of pituitrin (0·25 c.cm.)—one dose before leaving the theatre and repeated at intervals of one hour—with what appeared to be considerable success.

In conclusion, I wish to acknowledge the valuable assistance in the examination of blood and gastric contents I have had from Dr. Alexander Lyall.

A CASE OF
TUBERCULOUS POLYSEROSITIS WITH PREDOMINANT PERICARDIAL INVOLVEMENT.

BY L. S. T. BURRELL, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE CHEST, BROMPTON, AND TO THE ROYAL FREE HOSPITAL;
DOROTHY C. HARE, C.B.E., M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL FREE HOSPITAL AND ASSISTANT PHYSICIAN TO THE ELIZABETH GARRETT ANDERSON HOSPITAL;
AND
JOAN M. ROSS, M.D. LOND.,
SENIOR ASSISTANT PATHOLOGIST AND LECTURER IN PATHOLOGY AT THE ROYAL FREE HOSPITAL.

UNDER the generic term "polyserositis" is included a well-defined group of cases with chronic inflammatory thickening of the membranes lining the great serous sacs; often there are recurrent effusions, and the chief symptoms may be those of congestive heart failure. Many of the cases are regarded as "probably tuberculous," but clear proof of their exact nature may be difficult to produce. The following case is an example of polyserositis in a relatively early phase and running a more acute course than usual. It is reported because the tuberculous nature of the infection was established by culture, and the primary focus was discovered post mortem.

A previously healthy woman of 40, admitted for substernal pain, breathlessness, and continuous fever, was found to have a large pericardial effusion from which tubercle bacilli were grown in culture; there followed in succession left and right pleural effusions, ascites, and œdema of the legs. Enlarged supraclavicular glands were present from the outset, the liver became enlarged later, and the spleen was just palpable. An infection of the left quadriceps bursa developed, and from this also tubercle bacilli were grown. The general condition remained remarkably good for many months in spite of continual fever, but it gradually deteriorated, and the patient died two years after the onset from slow congestive heart failure and œdema.

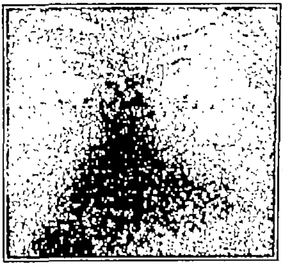
The post-mortem findings were:—

1. Long-standing caseating tuberculosis in one Fallopian tube (symptomless during life).

2. Tuberculous infiltration of the spleen with fibrosis, but little caseation, and infiltration of the same type in the cervical glands.

3. Chronic serositis of the pericardial, pleural, and peritoneal sacs.

FIG. 1.



Radiogram of chest taken on June 7th (patient standing). Transverse enlargement of cardiac shadow; no indication of pericardial effusion.

The early clinical aspect of this case was that of primary pericarditis with massive effusion, and resembled the group of cases published recently by J. A. Clarke, jun., as "clinically primary tuberculous pericarditis"[1]—i.e., cases in which active tuberculous lesions cannot be demonstrated elsewhere. This writer gives an analysis of 11 proved cases already published, and reports two others; he notes the long duration up to 22 months, the insidious onset, the continued fever, and the supervening cardiac failure and œdema with absence of signs of tuberculous disease elsewhere. The diagnosis was established in many of the cases by guinea-pig inoculation of the pericardial fluid, and in only one case were tubercle bacilli demonstrated in films from this source. Miliary tuberculosis was present in six out of nine necropsies, and active pulmonary disease was found only once; caseous mediastinal glands were found three times. The original focus of disease does not appear to have been established in the other cases.

Clinical History.

The patient, aged 40, at the onset of her illness had been in good health until May, 1926. She had been subject to "bilious attacks," and had been treated for minor chronic mastitis for a year or two. There was no history of respiratory trouble, and no personal or family history of tuberculosis. The illness began with a sense of oppression and pain under the lower end of the sternum, with breathlessness and fever. She was admitted to the Elizabeth Garrett Anderson Hospital on June 3rd, 1926, about four weeks after the onset. The symptoms then were substernal pain, pain and tenderness in the epigastrium, and cough of a few days' duration. The temperature was swinging between 100° and 103° F.

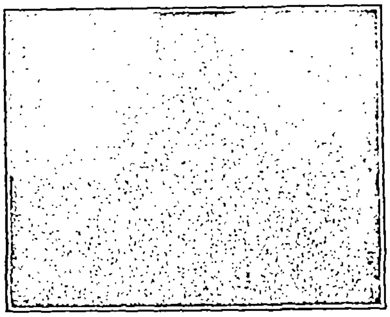
The præcordial dullness was slightly increased, but could not be defined on the left, where it merged into an area of dullness in the axilla; the heart beat and sounds were somewhat obscured, though normal in character. There were no signs of apical disease of the lungs, but there was dullness with weak breath sounds at the base of the left lung in the axilla. The abdomen was not distended, and there was no effusion; there was a tender epigastric swelling, but the liver was not apparently enlarged. There were several moderately enlarged and tender glands above the left clavicle; they were soft and not adherent. X ray examination showed increase in the cardiac shadow transversely, but was not diagnostic of pericardial effusion (Fig. 1).

---

[1] Clarke, J. A., jun.: Amer. Jour. Med. Sci., 1929, clxxvii., 115.

Two weeks later the diagnosis was still in doubt. There was increasing epigastric pain, and rigidity and swelling with persistent fever. The leucocytes were 10,000 to 16,000 per c.mm., with a normal differential count; the Wassermann reaction was negative; the urine was normal; there was some diarrhœa, but the stools were not abnormal; the urinary diastase index was found to be raised to 100 in a 24-hour collection. A diagnosis of pancreatitis was considered and, as the patient was acutely ill, laparotomy was performed on June 14th.

FIG. 2.



Radiogram of chest taken on June 24th (patient sitting). Typical globular shadow of pericardial effusion.

There was no general or localised peritonitis; the pancreas and stomach appeared normal, and the liver was moderately enlarged. The distended pericardial sac was bulging down through the diaphragm, and had displaced the left lobe of the liver downwards and forwards, simulating a tumour in the epigastrium. The appendix was removed, but no disease was detected in the neighbourhood.

On June 24th the pericardial effusion had increased, and the X ray plate now showed a typical globular shadow (Fig. 2). The pericardium was tapped, but only 25 c.cm. of fluid were withdrawn, owing to difficulty in aspiration; the fluid was straw-coloured, and contained a few polymorphonuclear leucocytes and red cells; no organisms were seen. Tubercle bacilli were grown subsequently from the fluid by Dr. Lepper, who thus provided the definite diagnosis.

From July to December, 1926, the patient had open-air treatment with complete rest. There were attacks of breathlessness and one slight hæmoptysis; pleural effusions developed, but did not require tapping, and the abdomen became distended but without ascites. From January to July, 1927, the patient was in Brompton Hospital under Dr. Burrell. The serous effusions became larger, and were repeatedly tapped, and oxygen replacements were given in pleuræ and abdomen. Abdominal discomfort appeared to be relieved a few days after the introduction of oxygen into the peritoneum, and at the same time the temperature fell towards normal and the effusion reappeared more slowly than before.

In July, 1927, the patient was again transferred to the E.G.A. Hospital. The liver at this time was enlarged to the umbilicus, though the spleen was not palpable and there was still much pericardial effusion with attacks of breathlessness and præcordial oppression. Five months' open-air treatment followed, with slight improvement in the general condition at first. An infection of the left subquadriceps bursa developed during this period, however, and the tubercle bacillus was grown from this.

In March, 1928, the patient was definitely deteriorating. In April she was transferred to the Royal Free Hospital. Ultra-violet light treatments appeared to improve the condition for two weeks, when relapse occurred and treatment was stopped. On two occasions during these last months the pericardium was tapped in the axilla; 200 c.cm. of blood-stained fluid were removed, the first time with relief of symptoms, and the second time 600 c.cm. were removed but without relief. The pleuræ were tapped almost weekly, and amounts from 600 to 1000 c.cm. were removed. General œdema increased, and death occurred on June 2nd, 1928, after 25 months' illness.

Fever was continuous for the whole period; the temperature was never normal for more than two or three days at a time until about ten weeks before death, when the reaction failed. The symptoms and fever were rather more acute in the first six to nine months than during the middle period of the illness; the appetite and general nutrition were well maintained, and the general resistance of the patient seemed so remarkably good that until the last six months recovery seemed possible.

Summary of Pathological Examinations during Life.

Pericardial Effusion.—The tubercle bacillus was obtained in culture when examined in June, 1926, and in January, 1927, it was demonstrated in films.

Pus from Bursa.—Tubercle bacillus grown in culture.

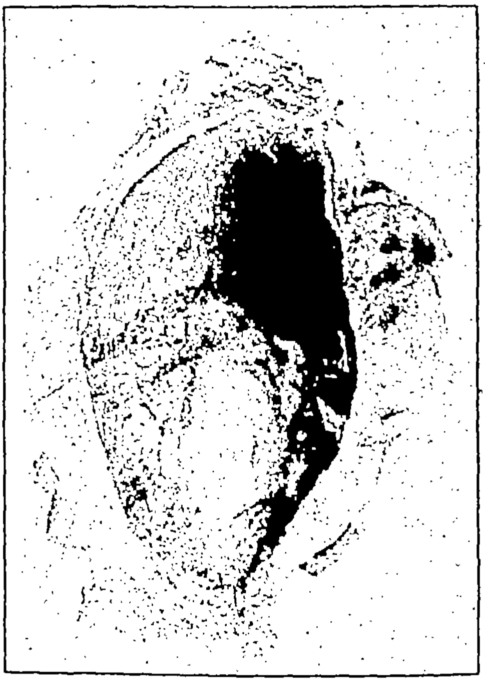
Pleural fluids, peritoneal fluids, and *sputum* were examined on several occasions, but the tubercle bacillus was not found.

Post-mortem Report.

Pericardium and Heart (Fig. 3).—The pericardial cavity is enormously dilated, and contains about a pint of clear fluid with flakes of fibrin. The visceral pericardium is generally thickened and fibrotic, and the parietal layer is a quarter of a centimetre thick. There are masses of fibrin adherent to the visceral pericardium over the left ventricle and in the posterior part of the sac. Microscopically there is extreme fibrosis of the parietal pericardium with a few foci of lymphocytes and plasma cells; in one or two areas giant-cell systems are present.

Pleural Cavities and Lungs.—Both cavities contain from one and a half to two pints of straw-coloured fluid. There is no thickening of the pleura except some light adhesions over the apex of the left upper lobe, which is partially collapsed; the lower lobe is completely collapsed. The right lung is congested but contains air. At each apex there is a single, very small, puckered scar. There is no active tuberculous disease.

FIG. 3.



Pericardium and heart.

Peritoneal Cavity.—There are dense adhesions in the upper part binding the organs together; in the lower part there is a little clear fluid with few adhesions. The peritoneum is slightly thickened.

The liver is much enlarged; there are dense adhesions over the surface, and it is bound to the neighbouring structures. The capsule is thickened. The cut section is firm and the lobular pattern clear; the centres of the lobules are congested, and the outer portion pale. Microscopically there is a slight irregular increase in fibrous tissue, chiefly periportal. In the centres of the lobules are widely dilated capillaries, and the peripheral cells contain fat vacuoles. There is no evidence of tuberculosis.

The spleen (Fig. 4) is very slightly enlarged, 11 cm. in length, rounded and firm with a thickened capsule. The cut surface is smooth, and shows the congested pulp with whitish, somewhat transparent-looking areas diffusely scattered throughout the organ. The smaller areas are fairly discrete, but the larger ones tend to become confluent and have no sharply defined margin. Only a few of these larger areas (1 cm. in diameter) show a yellowish opaque centre. Microscopically the pulp contains a large percentage of red corpuscles and a few lymphocytes; there is a diffuse increase of fibrous tissue, and the Malpighian bodies are very small. Throughout the whole spleen are areas which in some cases present typical giant-cell systems, and in others consist of necrotic, cellular debris and large pale-staining cells with pyknotic nuclei. Increase of fibrous tissue is considerable around these areas. No tubercle bacilli can be demonstrated in the sections.

Lymphatic Glands.—The mediastinal and supraclavicular glands are enlarged and fibrous. There is no caseation, but microscopically there are many typical giant-cell systems with considerable peripheral fibrosis.

The kidneys and suprarenals show no evidence of tuberculous infection.

The Fallopian Tubes.—The right tube is distended with caseous pus, and lies in the midst of dense inseparable pelvic adhesions. This is the only focus of caseating tuberculous inflammation in the body.

The left *subquadriceps bursa* is fibrosed.

Discussion.

The oldest tuberculous lesion discovered was the caseating focus in the Fallopian tube; the lungs were free from infection. In spite of the long history (two years), and the slow but widespread lymphatic spread of the bacilli from this focus to the serous sacs, the spleen, and the mediastinal and cervical lymph glands no other lesion was found which showed naked-eye caseation, although bacilli were actually grown from the fluid of the pericardial sac and quadriceps bursa many months before death. The absence of tissue necrosis and the marked degree of productive and protective fibrosis found in the spleen, the lymph-glands, and the thickened serosa were in strong contrast with the progressive caseation usually associated with widespread tuberculosis, where the symptoms and mode of death are due to the specific infection and toxæmia. In this case the symptoms and signs of congestive cardiac failure were prominent, and the effects of the widespread infection and of toxæmia relatively slight.

It seems reasonable therefore to suppose, on the clinical, pathological, and histological evidence afforded by this case, that chronic tuberculosis of the great serous sacs progressing to the production of "polyserositis," is a condition associated with a high degree of immunity to the infection, and that in more chronic cases than ours the infective element is slowly submerged as the clinical picture becomes one of mechanical obstruction to the heart and circulation.

Clinical and Laboratory Notes.

BREAD OR TOAST FOR DIABETICS?

BY R. D. LAWRENCE, M.D. ABERD.,
M.R.C.P. LOND.,
CHEMICAL PATHOLOGIST, KING'S COLLEGE HOSPITAL.

THE question whether bread or toast is better tolerated by diabetics does not seem to be definitely settled. Theoretically it might be expected that, weight for weight, toast would be worse, because it contains more carbohydrate than bread in the proportion of 70 per cent. to 50 per cent., water being driven off in the process of toasting and the carbohydrate concentrated. There is also no evidence that any chemical change from starch to dextrin involved in toasting makes the carbohydrate of toast more slowly absorbed or capable of producing less glucose on digestion. However, some recent observations by Payne[1] suggested that toast, in the form of rusks, was better tolerated than bread. As most diabetics prefer to have any bread allowed in the form of toast (the taste of dextrin being usually considered more appetising than starch), it has seemed worth while to decide the question by the following experiments.

The effect on the blood and urine sugar of 2 or 3 oz. of bread was observed in two people with mild diabetes, and on subsequent days the effect of the same weight of bread, off the same loaf, toasted hard. It will be noticed that such toasting reduced the weight of the bread to nearly half. Tea and a little butter was given along with the bread or toast, to make the conditions of the experiment as normal as possible. The meal was given fasting in the morning.

Remarks on the Experiments.

The blood-sugar concentration before and after the meal is shown in the Table as mg. per 100 c.cm. The degree of glycosuria corresponded closely and is not reported.

Time in hours :—		0	½	1	1½	2	3
Case 1 (aged 16).	Bread 3 oz. ..	99	213	221	199	165	—
	Toast 1½ oz. ..	95	216	243	181	163	—
Case 2 (aged 60).	Bread 3 oz. ..	143	—	250	—	191	153
	Toast 1⅝ oz. .	123	193	310	—	150	103
	Bread 3 oz. ..	114	170	200	—	104	82
	Toast 1⅝ oz. .	100	181	260	—	186	130

It will be noticed that there is no constant difference in the blood-sugar curve produced by bread and its toast equivalent. In Case 2, where four experiments were carried out, there is considerable difference in the degree of hyperglycæmia, sometimes in favour of bread and sometimes of toast. The high fasting blood-sugar in the first experiment was certainly caused by an admitted excess of diet for the previous few days, which no doubt influenced unfavourably the whole level of the curve. With this exception, the curves tend to show a more rapid absorption and higher hyperglycæmia after toast than bread. But it is felt that any differences observed are within the range of error in such experiments and may be caused by slight natural variations in rate of digestion, absorption, and conditions of the carbohydrate stores and tolerance. Again, as the blood estimations were not carried out at very close intervals, the highest point of the curve may have been obtained in one experiment and missed in another.

The conclusion may be drawn that no appreciable difference can be observed in the diabetic with amounts of bread and starch which contain equal amounts of carbohydrate.

Summary.

The hyperglycæmic effect of bread has been compared with that of an equal amount of bread thoroughly toasted and no appreciable difference has been observed in two mild cases of diabetes. One may reasonably infer that, weight for weight, toast is worse tolerated than bread because it contains more carbohydrate.

EFFECT OF ULTRA-VIOLET RADIATION ON THE INCIDENCE OF TAR CANCER IN MICE.

BY ALICE C. KOHN-SPEYER, M.A. OXF.,
WORKING IN THE DEPARTMENT OF EXPERIMENTAL PATHOLOGY, LISTER INSTITUTE.

IN THE LANCET last year (1928, ii., 1070) Dr. G. M. Findlay reported that "when mice are tarred and exposed to ultra-violet light at the same time the period necessary for the induction of cancer is shorter than when either tar or ultra-violet light alone is employed." In the hope of obtaining tar cancers rapidly for treatment it was thought expedient to use Findlay's method. The results (which for some unascertained reason differ from Findlay's) are reported below.

Methods.—All the mice were tarred twice weekly with a gasworks tar kindly supplied by Dr. E. L. Kennaway.

---

[1] Payne, W. W.: THE LANCET, 1927, ii., 1336.

(1) A batch of 20 mice were tarred twice weekly and also irradiated daily by means of a mercury-vapour lamp of the same make as that used by Findlay (Hewittic Co.'s Ulviare Y.2 burner, at 18 inches distance). Each irradiation lasted at first two minutes, but the time was gradually increased to five minutes, and was after eight weeks maintained at that dose. Fig. 1 shows the periods at which warts appeared in the 14 mice which survived long enough.

FIG. 1.

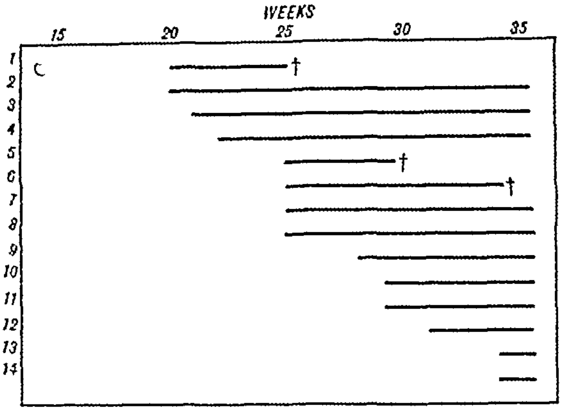


Chart showing the results of tarring mice and exposing them to ultra-violet radiation (old lamp). In this, as in Figs. 2 and 3, the black lines begin on the date at which warts appeared, and the cross indicates death.

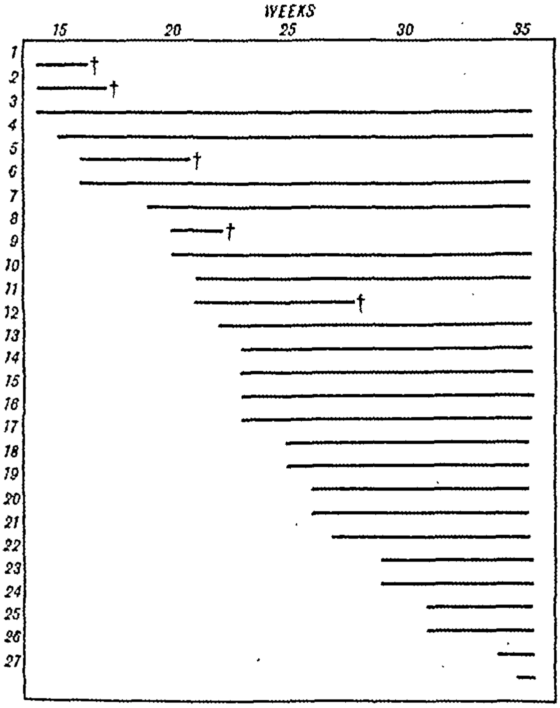
(2) As controls for the above a number of mice were tarred in the ordinary way without exposure to ultra-violet radiation. Fig. 2 shows the time of wart formation in 27 of these which survived until warts appeared. These controls indicate that the tars used by Findlay and by myself were about equally potent.

FIG. 2.



Control series of mice, tarred only.

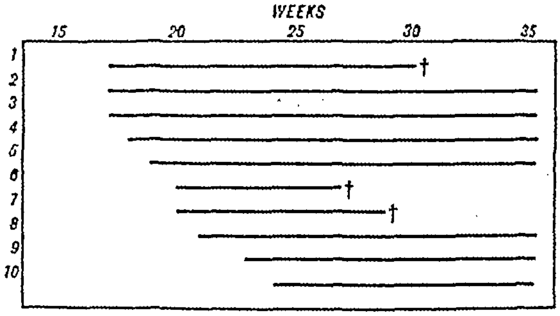
(3) Since there was no acceleration of wart formation in the tarred and irradiated animals, a second series of mice were similarly tarred and irradiated, but with a different (new) lamp of the same make. Fig. 3 shows the result of this experiment.

(4) A further series of 28 mice were given similar doses of ultra-violet light only (without tarring); 10 of these were radiated for eight months and 18 for six months; no warts have appeared in the 15 survivors up to now—i.e., a month after the radiations were stopped.

(5) Eight rats were tarred and irradiated as above for six months. One of these showed persistent dermatitis, but none of them developed warts.

It is evident from the figures that the ultra-violet light did not shorten the time necessary for wart production in the above experiments. While Findlay got ulceration of the skin with two to three minutes' exposure daily, in my experiments no ulceration occurred even when the exposure was increased up to five minutes. In the radiated mice the hair grew more rapidly over the epilated and treated area than in the controls; they were therefore re-epilated with sodium sulphide in the fourth and seventh weeks; later, since sodium sulphide alone sometimes causes ulceration, the treated area was epilated with forceps. In the third experiment epilation with forceps was employed from the start. The reason for employing a new lamp in this experiment was that the lamp used in the first instance was old and might therefore have been deficient in short ultra-violet rays. It will be seen that, although warts appeared slightly more quickly in the mice on Fig. 3 than in those on Fig. 1, in neither was the wart formation more rapid than in the controls (Fig. 2) which were tarred but received no ultra-violet radiation.

FIG. 3.



Results of tarring, together with ultra-violet radiation (new lamp).

It is difficult to decide why these results differ so markedly from Dr. Findlay's. It seems possible that his epilations and radiations may have produced more skin injury than mine, and that the acceleration noted by him was due either to this or to some other as yet undetermined cause. It does not appear to have been due to ultra-violet radiation alone.

Conclusion.—Under the conditions of the experiment irradiating mice with ultra-violet light as an adjunct to tarring was not found to produce warts more quickly than tarring alone.

I wish to thank Dr. Thomas Lumsden for help and criticism, and the British Empire Cancer Campaign for a grant.

NORTH STAFFORDSHIRE HOSPITALS.—The Bishop of Lichfield recently dedicated seven endowed beds in the Henry J. Johnson Ward of the North Staffordshire Royal Infirmary. The trustees of the will of the late Miss Dora Twyford have just allocated to the Infirmary a sum of £50,000, in addition to £13,000 already assigned to it from the same source.—The Orthopædic Hospital of the North Staffordshire Cripples Aid Society is to be enlarged at a cost of £18,000 to £20,000. The new buildings, which will comprise a new out-patients' department, an operating theatre, an X ray department, and additional accommodation for the staff, are said to be regarded by the Ministry of Health as "a model for orthopædic hospitals." A canteen will be provided for the use of out-patients and those accompanying them. Eighty per cent. of the patients in and out, are cured. In-patients cost £2 9s. per week.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society on Dec. 9th with Mr. DONALD ARMOUR, the President, in the chair, a discussion on

HEAD INJURIES

was opened by Mr. WILFRED TROTTER. This branch of surgery, he said, was encrusted with tradition embodying doctrines of which some were still useful and living while many had outlived their vitality but were unable to die. If it was possible for abdominal surgery already to be encumbered by superseded ideas, it was natural to find that the old and slowly developed surgery of head injuries showed the same tendency in a much more marked degree. In fact it might be said that one of the chief needs of this branch to-day was a resolute overhauling of its inheritance of ideas.

Knowledge of head injuries had developed in three stages which were distinct enough to be usefully recognised. The first was a period of slow progress extending up to but not far into the last third of the nineteenth century. This might be called the early period; it passed into the middle period, which comprised a space of some 30 years or so from the 'seventies of the last century and was chiefly characterised by the entry of the experimental physiologist into the subject. Finally, the last 20 or 30 years might be regarded as a third period whose essential feature had been the harmonising of experimental and clinical knowledge and a resulting tendency to simplification.

The characteristic of the *early period* was that the subject was completely dominated by fractures of the skull. Fracture came to be looked upon as the essential event in head injury—cerebral manifestations being mere complications—and this conception persisted long after it had ceased to be useful and had become misleading. It survived to-day, though no doubt in diminishing strength, among medical men, and in the lay and especially the legal mind it persisted with indestructible vitality. In fact, the presence of a fracture made it probable, though not certain, that considerable distortion of the skull had occurred, and therefore gave a rough measure of the violence to which the brain had been exposed. But the absence of a fracture was no evidence that the skull had not been considerably distorted and the brain seriously damaged. The term "concussion of the brain" perpetuated the view that the familiar instantaneous traumatic paralysis it described was due to the brain having been shaken about inside the skull and having sustained some mysterious though happily transient detriment thereby. The evidence now available showed that the doctrine conveyed by this word was not correct, and that the state in question was due to the momentary and general anæmia of the brain which accompanied a general distortion of the skull.

In the *second period* the help of the experimental physiologist had transformed the surgery of head injuries from a largely empirical art into something approaching an applied science. They showed that circulatory disturbance was the chief mechanism by which cerebral symptoms were produced, and taught what symptoms were produced and how they were produced by a progressive lesion compressing the brain. Yet it must be admitted that their work had not resulted in as much progress on the clinical side as it had seemed to promise. The exposition of the new doctrines was apt to seem to the clinician abstruse and remote from practical reality; and the subject was so much dominated by the theory of the localised compressing lesion that the surgery of head injuries had inherited from this middle period a fallacious clinical impression that head injuries were largely a matter for urgent operations which could and should be undertaken in a considerable proportion of cases with reasonable expectations of success. Expositions of theory which had come down from the experimental school contained the principles necessary to a practical grasp of traumatic cerebral lesions; yet they did not always reduce the confused and multitudinous events of clinical experience into order and significance.

The Typical Traumatic Lesion.

In the *modern period* surgeons had been chiefly concerned with contusion, the typical traumatic lesion of the brain. Recognition of the importance of distortion of the skull had made it clear that besides direct and polar (or contrecoup) bruising to which the brain was liable under violence, the whole organ was subject to stresses and deformations which must expose its whole surface and substance to damage. Probably widespread bruising was always present after any injury at all severe, and though not in itself seriously destructive, it gained very rapidly in gravity according to the extent to which the parts of the brain in the posterior fossa of the skull were involved. Contusion here was perhaps the commonest cause of death and the commonest cause of ultimate failure in apparently successful operations for hæmorrhage. In every case of severe injury all the clinical manifestations were sketched on a background of contusion phenomena of all grades of definition. While contusion was so largely responsible for the gravity of head injuries it had in comparison with gross hæmorrhage one very favourable character—viz., that it could scarcely give rise to pressures beyond the order of the venous pressure. It could not therefore produce gross capillary anæmia and the accompanying paralytic states. Thus it rarely called for urgent operations and in so far as it was amenable to treatment at all could, and should, always be dealt with by milder measures—at any rate in the early phases. The remedies arranged roughly in the order of increasing severity of symptoms to which they were applicable were: rest, posture, hypertonic derivation (oral, rectal, or intravenous), lumbar puncture, and decompressive operation. None should be neglected and each was capable of giving brilliant results.

During the late war a large group of clinical phenomena, previously assigned to the uninviting chaos of "traumatic neurasthenia," had been found to be due to definite organic brain injury in the nature of minor and unresolved contusions of the brain substance. As soon as their true pathology was known, their symptoms were found to be well defined, the three characteristic elements being headache, giddiness, and minor mental changes. This clinical picture was a very common result of head injury of any grade. The unresolved contusion showed itself as an indefinitely persisting but variable elevation of the intracranial pressure, and its symptoms had that close dependence upon the state of the venous pressure which experimental studies had proved must be present in such circumstances.

The Clinical Picture.

Dr. C. P. SYMONDS said that Mr. Trotter had done more than anyone else to illuminate this subject. The picture which Mr. Trotter had drawn of cerebral contusion had enabled others to recognise what was a very clean-cut clinical syndrome. The lawyer was always looking for objective evidence, and what he liked to be able to show was a radiogram of a fracture of the skull. It was necessary to teach the lawyers not only that severe cerebral injury could occur without fracture of the skull, but that the symptoms of such cerebral injury were quite well defined. The symptoms of cerebral contusion were easily recognisable by those who took a careful history; for a long time they had gone by the ill-used name of "traumatic neurasthenia"—a name which usually concealed all that it was intended to cover. The difficulty of diagnosis rested largely on the absence of physical signs in these patients, so the symptoms had to be critically analysed. They usually presented themselves under three headings—headache, giddiness, and symptoms of minor mental disorder. The mental symptoms were often difficult to evaluate because of the complicating factor of the "compensation neurosis" which was often added to the organic cerebral symptoms. Headache and giddiness were, therefore, symptoms of great importance. A point about the headache of cerebral contusion which he found it difficult to understand was the latent interval which was common between the accident and the onset of disabling headache; this interval might be of days' or even weeks' duration, and it was something not likely to be invented by a malingerer. The patient described it in terms of pain rather than discomfort. A man with neurosis might complain of agonising headache, but he would say it was a numbness or pressure rather than a splitting or throbbing pain; and it was more continuous. The headache of contusion, on the other hand, was intermittent, or if it was continuous it showed remarkable exacerbations, likely to be associated with increase of intracranial pressure—e.g., in stooping or straining at stool. The giddiness of which contusion cases complained was a transient affair—a momentary sense of loss of equilibrium—which bore a definite relation to posture; thus it might come on when resuming the erect posture after lacing the boots; or after quickly turning his head to see if the way was clear the patient might become incapable of crossing the street. These symptoms together formed a very characteristic picture of a bruised brain. The value of the mental symptoms was harder to assess, though critical analysis of them would often allow distinction from those of a neurosis. The neurotic patient might complain of inability to concentrate, and of excessive mental fatigue, though he might still manifest surprising agility in debate. In true cerebral disease there was a slowing of thought, a defective memory, a true mental fatigue.

The long interval between the injury and the development of symptoms was no doubt often due to the fact that so long as the patient rested he was free from symptoms, but this was not always so. Histological research, especially in the laboratories of Otaka and Penfield, had shown that minor injury to the brain might result in very slow changes in the neuroglia—changes which in themselves led to vascular displacement and possibly to vascular congestion.

Radiography of the Skull.

Mr. H. K. GRAHAM HODGSON demonstrated a series of films illustrating the radiographic appearance of the skull after fracture. In radiographing the skull, one threw complicated shadows on the plate, and unless standard views were used, in which the skull bore a definite angle relationship to the film, the picture was hard to interpret. Such measurements as the nose-chin, or nose-chin-forehead, were fallacious, owing to the varying sizes of noses, and of projection of chin and forehead. Therefore in cranial radiography it was essential to take a definite line, such as the outer canthus of the eye to the external auditory meatus, and make it bear a definite angle to the film. Further, if only one or two anteroposterior radiograms and a lateral one were taken, many fractures of the skull would be missed; so it was necessary to search by means of 7 or 8 standard views. At the suggestion of Messrs. Kodak, he had tried superimposing two films, and this showed the nasal bones, cartilages, and soft parts outlined, and also the alteration in the contour of the nose. Another important view of the nasal bones was taken with the film underneath the nose, looking straight down through the vertex of the skull.

Dr. GEORGE VILVANDRÉ said that at the London Hospital it was the routine practice to take stereoscopic views of skulls about which any question arose. He thought that the lateral view and the anteroposterior view were of only limited value, and that no really useful knowledge could be gained with X rays unless stereoscopic views were taken. Looking at a picture of a cranial fracture was liable to lead to excessive concentration on actual bony damage and to comparative neglect of the injury to the brain. Thus the heads of two schoolboys collided in a game of football, and one of them got a depressed fracture of the frontal bone. From the appearance of the fractured bone it was judged that an operation would be necessary, but nothing operative was done, and the boy made a good recovery. Sometimes a radiogram might give a misleading impression and sometimes the patient was so ill that radiography was for the moment out of the question.

Contusion Headaches.

Dr. GEORGE RIDDOCH said that like Dr. Symonds he was puzzled by the nature of headaches coming on after cerebral contusion. As had been pointed out, the brain might be injured without a fracture and consciousness might be lost as a result of concussion. But contusion headaches might follow head injury where consciousness had never been lost. This class of case presented great difficulty, especially in the absence of physical signs, even in the presence of severe contusion headaches. Though P investigations might do something to eluc origin of headaches developing after a lo period the question was not yet answe There were changes in the brain, but Dr. thought there might also be external ch the meninges, comparable to the chronic a itis or meningitis serosa circumscripta s found after spinal injuries. He urged the ance of keeping head injury cases in be than was customary. Though this was in a general hospital an attempt should be improve on the usual few days' rest before the was shunted off to an infirmary. This i he thought, would eliminate some of the mild In the attempt to reduce intracranial pre had found it very beneficial to keep the propped up in bed and give hypertonic sal rectum and magnesium sulphate twice a day. patient should be asked to retain the rectal in for a quarter of an hour. For severe cases h recently tried replacing some cerebro-spinal with air; in a proportion this had allayed headache, perhaps by altering the condition arachnoid in the region of the superficial contu and by re-establishing the cerebro-spinal fluid circ tion. The decompression operations successfu practised in the late war had not proved so successf he thought, for the more general injuries of ci life. Their failure was especially marked if th patient was demoralised and neurasthenic befo operation. In such people the last condition wa often worse than the first.

Sir JAMES DUNDAS-GRANT recalled to the meeting a statement by Erichsen in connexion with "railway spine"—namely, that in contusion and concussion of the spine, after the more acute symptoms had passed off, great relief was afforded by small doses of perchloride of mercury. The speaker had seen many cases with definite vertigo without apparent injury to the internal ear in which this drug gave gratifying results. The reason was clearer now it had been found that slow and more or less inflammatory degenerations took place in the neuroglia.

Mr. TROTTER, in a brief reply, confessed he was unable to answer the one question which Dr. Symonds had put to him. It concerned one of the most mysterious problems in cerebral pathology; that a patient might enjoy apparently normal health for a definite period, and then develop disabling symptoms from an injury which must be considered to have been present all the time. He had been particularly interested to hear of the cases of depressed fracture which had recovered without operation. He had long felt that the ancient doctrine that (except in the very young) any fracture must be operated upon, was wrong. The reason for the view had been the risk of epilepsy. He now believed that the risk of epilepsy from a simple depressed fracture was no greater than the risk of epilepsy from an operation involving incision of the dura mater.

HUNTERIAN SOCIETY.

At a meeting of this Society on Dec. 16th Dr. **Ernest Young**, the President, took the chair, and a discussion on

Whitlow and its Complications

was opened by Mr. **Zachary Cope**. He deplored, he said, the tendency in the medical profession to instruct students minutely in the diagnosis and treatment of such rare conditions as pituitary tumour, while omitting any detailed information on common and important affections such as whitlow. The average student was woefully ignorant on this subject and the text-books allowed it the most casual and scanty description. In a recently published American text-book, "Nelson's Loose-Leaf Living Surgery," there were 100 pages devoted to this condition, while an important English text-book allowed it only 15½ lines.

The word "whitlow" was derived from the word "whitflaw," meaning a "rent" or "tear," and not (as he had been at first inclined to suppose) "from white flow," or flow of pus. And, in fact, the infection nearly always did enter through an abrasion, though occasionally it might be blood-borne; further, it was specially liable to occur when the patient was run down. The simplest form of whitlow was the subcuticular variety. This type, which was annoying but not dangerous, was caused by an invasion of the subcuticular tissue by the organism, usually either a streptococcus or a staphylococcus. The streptococcus was the commoner causative organism in these cases, and the more troublesome, often giving rise to the condition of paronychia or perionychia. The successful treatment depended entirely on thorough drainage; the overlying cuticle must be removed and if the infection had extended under the nail this must also be cut away as far as was necessary. It was useless to leave even a small area of infection covered by nail, as the finger would not heal unless the whole septic area had adequate drainage. In the second, or subcutaneous, form of whitlow the condition was much more serious because the infection was in a prison, bounded posteriorly by the bone and anteriorly by the dense skin, while at the base of the phalanx it was on dangerous ground owing to the propinquity of the tendon sheath. This form of whitlow was rightly described as a "felon," and Mr. Cope proposed to show what routes the felon, or rather the microbe, might follow in making its escape.

In the first place it might make use of the blood stream. This he likened to invasion of territory by means of aeroplanes; it could not be stopped and was usually fatal. Secondly, the infection might follow the lymphatics. This corresponded to a state of affairs in which the invading army had captured the railways. It was slower than a blood stream infection, and the lymphatic nodes represented stations, or points at which the invasion could be held up. The third method was invasion by cellular contiguity; the army was entering by the country roads, often rough ones. This method was slow unless the army struck an arterial road, which was represented by the tendon sheath.

Treatment.

The first principle to be followed in the treatment of whitlows was anatomical diagnosis. It should always be remembered that tension was the cause of pain, and that tenderness on pressure gave the site of tension. In the palmar space, he added, the pain might not be marked because the space was larger and therefore the tension less than elsewhere. In diagnosing the site of the pus, swelling, tenderness, position, and movement of fingers should all be taken into consideration. It was a bad policy, though followed by most general practitioners, to incise over the maximum swelling. An anatomical diagnosis should be made first, and the best incision employed for the condition found. Infection of the tendon sheath of the ring finger led to bulging in the palm, of those of the middle and index fingers to bulging of the thenar eminence. The pain in a distended palm becomes less as the tissues become sodden and the nerves poisoned by the toxins of the pus.

Preventive measures were important. These should consist of early treatment of abrasions with iodine, all horny skin being first shaved away from the region of the cut. A dressing should always be used, and a strapping dressing was essential if it was to keep in place. In the United States the percentage of whitlows in factories had been enormously reduced by these simple measures. When incision was necessary it was important for the surgeon to see what he was doing, and to give himself plenty of time to see. For this reason the incision should always be made under a general anæsthetic or gas, not under a local anæsthetic such as ethyl chloride. A tourniquet was extremely valuable as it gave one a dry field and enabled one to see the pus. Drainage tubes should never be put into the palm; a gauze wick or a piece of rubber tissue was enough. Finally, the drainage must at all costs be adequate. In making incisions it must be remembered that finger incisions should be at the side, not in the mid-line. A circular flap was sometimes used but the speaker did not think this was necessary. If the palmar space was infected the incision should run the whole length of the hypothenar eminence, and a slight incision should always be made above the wrist on the ulnar side. An incision over the thenar eminence should always stop half an inch above the wrist to avoid damage to the deep palmar arch or its branches. After-treatment should consist of moist or dry dressings and baths. Active movements should be begun as soon as the inflammation had subsided. Radiant heat and ultra-violet light were valuable, and passive hyperæmia could be used, but only after incision.

Septic hands, Mr. Cope concluded, caused more loss of working time than acute appendicitis, and to anyone of discrimination appendicitis was preferable.

A Branch of Major Surgery.

Mr. **Herbert Carson** said that the surgery of the hand was major surgery which had been too long masquerading as minor. It was relegated to junior members of hospital staffs who had had no adequate preparation. In reality the subject was simple once the anatomy of the part was thoroughly mastered, and if the case was seen early. As a rule, patients came late with the whole hand swollen, which greatly increased the difficulties of diagnosis. As far as prophylaxis went all factories should be supplied with a casualty room and a competent nurse. Unfortunately, many cases occurred in sempstresses and scrubbers, who did not work in factories.

The four types of whitlow were: pulp infections with or without paronychia, tenosynovitis, invasion of the fascial planes, and lymphangitis, in which the general condition was serious and the local signs comparatively slight. The danger in pulp involvement was necrosis of the terminal phalanx owing to interference with the blood-supply by the swelling. In tenosynovitis sloughing of the tendon was to be feared, and the same result might occur in the third type. In the case of lymphangitis there was danger of death without local loss. In the case of the two earlier conditions treatment should be by immediate and adequate incision. In the case of abscess between the fascial planes there was time for thorough examination and exact diagnosis. When lymphangitis was present no operation must be performed until absolutely necessary, for premature operation might do more harm than good. Mr. Carson advised all surgeons interested in this subject to read Kanavel's book, which, though arranged in a confusing manner, realised is that it galvanises existing hospital dispensary work in eye diseases." India has a population of 320 millions, and eye disease is only one of the many important medical problems which confront the authorities. It is obvious that only a government agency, or one working closely with the government, could deal with the problem as a whole, and that all existing medical agencies might have their place in any comprehensive scheme. The question that arises is what is the standard of their treatment? Is it not capable of improvement? It must be admitted that the teaching in ophthalmology during the ordinary medical curriculum in India, as in other countries, has in the past been decidedly scanty, and the efforts now being made to remedy the deficiency cannot affect men who have already qualified. Those who work in outlying dispensaries are apt to fall into a routine application of favourite remedies, not necessarily the most efficient. In the ordinary post-graduate classes as a rule not much attention is given to eye work; if an examination for promotion to a higher grade follows the course, as used to be the case in India, matters of detail, so essential to successful treatment, tend to take a secondary place. A well-thought-out short "refresher" course in the treatment of trachoma, of a week's duration, given by an expert at a big hospital in a suitable centre, would do much good.

Such was the practice in Vienna before the war. The course here included lectures and demonstrations of suitable cases, and daily attendance in the trachoma clinic, where the usual operations on the lids were taught to practitioners working in trachoma districts, who went back to their work keen to carry out what they had learnt. There is an inevitable tendency in districts where trachoma is common to get bored with the treatment and to devote more time and energy to (say) operations on cataract, which give more dramatic results. It should not be forgotten, however, that inefficient treatment, or the failure to do a lid operation at the proper time, may result in a trachoma patient losing the whole or part of his sight and being a burden to himself and the community for perhaps 50 years; whereas the expectation of life of a senile cataract case is only a fraction of that period. If it were possible to send out a keen man, well trained in ophthalmology, who would camp for a short period near each outlying dispensary, who would see the patients with the sub-assistant surgeon in charge, offering him suggestions and advice, and generally helping him with the treatment of his eye cases, it would tend to raise the standard of his treatment. And this could be done without casting any slur on the present workers in India. The teaching in ophthalmology in Austria before the war was as good as, if not better than, any in Europe, yet they found it useful to adopt a system of "refresher" classes.

THE HARBEN LECTURES AND VITAMIN B.

By some curious twist of taste or habit, very few people generally go to the Royal Institute of Public Health in Russell-square to listen to the annual Harben Lectures. It is a pity that this should be so, for learned and distinguished lecturers commonly have personality as well as something to say and they will say it all the better under the stimulus of a good audience. We hope at any rate that plenty of people who did not hear the series lately given by Prof. R. A. Peters of Oxford on the "Coördinative Biochemistry of the Cell and Tissues" will read his discourses which are in course of publication in the *Journal of State Medicine*; they tell us a good deal and, which is better, suggest much more. Prof. Peters begins by pointing out that descriptive biochemistry has developed into dynamical biochemistry. At first it was necessary to isolate and identify the various chemical substances in live animals and plants and there is still evidently much to be done in that line. But just as biological theory has arisen on the descriptive foundation of the early naturalists, and zoologists now want to know how animals live as well as what animals there are, so biochemists are becoming more and more concerned with how live matter works on the basis of the substances which have been identified.

Life consists of a continued and orderly stream of reactions; there is nothing chaotic about it and Prof. Peters addresses himself to the imagination of some structural system on which this fundamental characteristic might depend. It is obviously not enough to appeal, as many have done, to the colloidal condition of the substance of cells; a colloid mush might reach any limits of incoördinate behaviour. He points out that some units of living matter are so small that the ordinary statistical physico-chemical laws can hardly apply. An organism which is just visible (0·25 μ) occupies about the same volume as 555 million molecules of water and by our ordinary conceptions will contain only one hydrogen ion at pH 7·0; filter passers, with perhaps one-hundredth the bulk, will be still more remote from the common circumstances of chemical reactions. The perceptible histological structure of a cell fails altogether to provide a framework on which the due sequence of its activities might be arranged. Prof. Peters suggests that it is now legitimate to imagine a molecular framework. It is known that molecules at surfaces are orientated in a regular fashion; the molecules of palmitic acid, for instance, spread in the thinnest possible film on water, are like sausages tightly packed together with the methyl group always towards the air. The interior of a cell may have an elaborate molecular structure made up on this kind of plan and ultimately based on the surfaces of the proteid constituents which form a sort of central mosaic from which chains of other molecules radiate in an orderly way. The activities of this structure are controlled in the main by changes of reaction and consequent changes in absorption, and in this way, the lecturer urged, it was possible to picture the dynamic chains of chemical reactions taking place, controlled inside the cell not by the ordinary laws of mass action but by "the exigencies of the matrix;" he did not, however, explain whether by this he meant the needs of the proteid basis in a teleological sense or the inevitable results of its constitution. Such disciplined speculation needs no defence, and from it Prof. Peters turned to the hard experimental facts about vitamin B to which he and his collaborators at Oxford have devoted so much attention. The simple fact that there was something in rice polishings and yeast which prevented and cured beri-beri has developed into a complicated and tangled tale. Prof. Eijkmann's original discovery in applied bacteriology has indeed been so fruitful in opening up new fields of knowledge that the award of a Nobel Prize to him the other day seems particularly appropriate.

We now have B_1, which cures polyneuritis in pigeons, and B_2, which cures a dermatitis in rats, which seems to be the same thing as pellagra in man; on these and their certain distinctness Goldberger, Chick and Roscoe and other observers are agreed.

B_1, or "torulin" as Prof. PETERS calls it, seems to be generally necessary for the growth of all cells—rats, pigeons, bacteria, and tissue cultures; yeast cells can make it for themselves. But to these a third, and possibly a fourth, factor in the vitamin B complex, both necessary for rats, have to be added, and yet a fifth, needed by pigeons (which can do without B_2) but not by rats. All of these minister in some way or other to the maintenance of the normal metabolism of animal organisms; at the moment the complexities of the situation are evidently beyond anyone but the experts. We suspect, however, that Prof. PETERS is right when he claims that a definite test such as the ability to cure polyneuritis in a pigeon fed on polished rice is a safer guide than the measurement of a vastly complex event such as the growth of a young rat. And in his third lecture Prof. PETERS takes up a very interesting and relatively neglected side of the vitamin question—how the deficiencies produce their symptoms. Animals deprived of vitamin B in a broad sense waste because their tissues cannot use the food. Food is absorbed but there is an internal starvation which leads secondarily to loss of appetite. This failure is shown by the fact that glucose injected into the blood of animals deprived of vitamin B does not disappear as quickly as in normal animals. Prof. PETERS and his co-workers have endeavoured especially to ascertain what B_1 does and they make out a good case for believing that this is the fraction particularly concerned with carbohydrate metabolism, and especially with the removal of lactic acid in the Meyerhof cycle. The symptom of opisthotonus in pigeons appears to be directly due to an excess of lactic acid in the brain and it is cured most quickly by injecting concentrated preparations of torulin locally. Absence of another fraction of B leads to heart-block and a remarkably slow pulse, and the puzzling question of œdema (emphasised in the clear clinical distinction between "wet" and "dry" beri-beri) may find its solution in another factor which coöperates with torulin in regulating the distribution of water in the body. Finally, there is evidence of a factor concerned with the proper metabolism of proteids, present in yeast extracts containing B_2. The answer to the question whether vitamin B is concerned with metabolism as a whole or with proteid alone or carbohydrate alone is that it influences all three. Exactly how remains to be discovered. Meanwhile we should all do well to take Prof. PLIMMER's advice and eat plenty of it.

COSHAM HOSPITAL.—The report of the committee appointed to inquire into animadversions upon the administration of this Ministry of Pensions hospital has now been published, and is a complete vindication. It will be remembered that a coroner's jury which sat upon the death of a patient found a verdict that he died as the result of unnecessary violence and declared in a rider that "very grave maladministration" existed at the hospital. The committee are "satisfied that there is no ground to justify" the rider, and add that "on the contrary, we find that the hospital is well and properly administered, and we have formed a high opinion of Dr. Paul's capacity as an administrator of this institution." Their efforts to obtain the testimony of witnesses who could bring criticisms to bear on the administration of the institution proved singularly unsuccessful, only one such witness coming forward. Other witnesses who had responded to their invitation "could only speak well of the hospital." The committee consisted of Sir Frederick Willis, Mr. J. Bromley, M.P., Major J. B. Brunel Cohen, M.P., Mr. Isaac Foot, M.P., Sir Adair Hore, and Dr. E. Mapother.

Annotations.

"Ne quid nimis."

EPSOM COLLEGE.

WITHIN a few days Epsom College will reach the seventy-fifth year of its life, having been established as a public school with a Royal Medical Foundation in 1855. The details of the Foundation are set out this week in an advertisement received from the College, and the claims in that advertisement are so accurate and so well advanced that we ask readers to consult what the College can say about itself, without repeating the story here. It is sufficient to say that a life of three-quarters of a century has been a record of increasing usefulness. But the message of the advertisement is—Why not subscribe to the support of an institution whose activities are so practical and whose design is so good? John Propert founded the College with the intention of providing education for 50 boys, the children of medical men whose circumstances precluded the boys from enjoying the opportunities usually at the disposal of the sons of the professional classes. From a further fund pensions are granted in response to suitable applications from medical men or their widows. The net result is that at least £9000 is required annually to meet the joint demand. And only a small fraction, some 6 per cent., of registered practitioners support the Foundation. Once again at this season of the year we urge upon our readers the strong claims upon them of Epsom College. The Medical Foundation is an integral part of the constitution of the College, and the College is a public school open to all, where the sons of medical men in association with lads of a comparable class can obtain a first-class education. One of the greatest anxieties which a medical man may have, an anxiety that haunts many during their professional life, is in regard to the education of his children. For the most part he pursues a calling which may not enable him to make large savings, knowing the while that incapacity to practise will as surely as death make the education of his children and the sustenance of his wife impossible for him.

The work of the College is carried on with energy, and its story through a long period of years has been, one of progress. But that progress has always been made in the face of financial difficulty. We believe that, at the season when the hearts of all are open to just appeal, that we in the medical profession can find no worthier object of generosity than the Medical Foundation of Epsom College, with its linked generosity towards our widows and orphans.

FIRST-AID IN CARBON MONOXIDE POISONING.

THE ever-increasing incidence of cases of poisoning by carbon monoxide, particularly by exhaust fumes from motor cars, points the need for organised first-aid treatment. In this matter New York seems to be ahead of our great cities. Yet science owes it to the researches of Haldane that the way in which carbon monoxide produces unconsciousness has been grasped. It acts by suspending the capacity of the blood to convey oxygen to the tissues. The air-hunger which results stimulates breathing, whereupon carbon dioxide is unloaded from the blood. But carbon dioxide is the main stimulus to breathing, and in its absence, apnœa may result, just when deep breathing is most needed. Full understanding of what occurs has led to a method of resuscitation in which carbon dioxide is used to stimulate deep breathing. The patient is made to breathe a mixture of oxygen and carbon dioxide; if he is unconscious, artificial respiration is carried out with the mixture. The combination first recommended was 5 per cent. carbon dioxide and 95 of oxygen, a mixture which some anæsthetists keep ready to hand in cases of respiratory failure. Reasons are now given for increasing the carbon dioxide to 7 per cent., which doubles the normal minute-volume of breathing without causing undue discomfort. We learn from the *Journal of Industrial Hygiene* for November, 1929, that the Consolidated Gas Company of New York at the present time have ten emergency trucks supplied with the needed inhalation apparatus, manned by crews of three. They respond to all notifications of leaking gas, to fires, and to all sorts of situations where asphyxia has occurred or is a hazard. The crews are thoroughly drilled in giving artificial respiration, and in handling unconscious patients. In 1926 they treated 789 cases; in 1927, 715; and in 1928, 850; in these cases the 5 per cent. mixture was used. Since March, 1929, the 7 per cent. mixture has been issued on 300 cases, with great advantage, in the opinion of the trained and expert crews.

THE PORT OF LONDON.

THE 70-mile reach of Thames from Teddington lock to the open sea forms the Port of London, in which one-third of the commerce of the United Kingdom is carried on. Dr. Charles F. White, who was appointed medical officer of health in September, 1928, tells us that in that year 27,711 ships entered the port, 15,936 from abroad. Of these 17,522 were inspected, and in 1463 conditions prejudicial to health were found: 1391 had dirty quarters, 97 leaky decks, 77 bad ventilation, 65 defects in sanitary conveniences, and 55 defects in lighting, while in 48 the crew's quarters were verminous. Rather over half the structural alterations ordered were made before departure. Water is usually taken from the mains, but there are 17 water barges, the water in which was never found contaminated. The water of a ship, among the crew of which several cases of diarrhœa had occurred, had been taken on board at Batoum and showed *B. coli* in 25 c.cm., and *B. ent. sporog.* in 10 c.cm.; its tanks were emptied and cleaned. Infectious cases are sent to the Port authority's hospital at Denton (Gravesend), and the ship spaces are disinfected by fumigation with sulphur followed by washing with izal. Fifty-four cases of tuberculosis and 20 of enteric fever were landed from ships. Handbills concerning free treatment for venereal disease are distributed among the crews; 121 cases came to notice, most of them gonorrhœal. No case of small-pox, plague, or yellow fever appeared, but six plague-infected (black) rats were found in a ship from Bombay. On this ship 30 rats were trapped, and 25 found dead, that is 55 in all, before fumigation by hydrocyanic acid, after which 22 more dead rats were found; no human case occurred. One group of five enteric cases were traced to water taken on board at Buenos Ayres. Of the total number of rats destroyed 11,425 were on board, 9890 ashore; of 1420 examined, only the six mentioned above were plague-infected. On 128 ships fumigated with sulphur the highest number of rats found dead was 320, the average 35, and 58 ships had none. On 47 ships fumigated with hydrocyanic acid the highest number was 106, the average 6, and 29 had none. We might perhaps deduce that hydrocyanic acid fumigation was favoured most by ship-owners who took most trouble, by rat-proofing and otherwise, to reduce the rat population of their ships. There was an outbreak of German measles on one of the six training ships lying in the Thames, otherwise these ships were healthy; only one case of tuberculosis was reported from them. Food inspection led to the destruction of 6018 tons of unsound food or its appropriate disposal. Of 50,000 ox-tongues, 6 per 1000 were found affected with actinomycosis; last year the figure was 20 per 1000, suggesting that shippers are now more careful. Caseous lymphadenitis was found in 4 per cent. of Australian and South American mutton carcasses, and condemned accordingly. No undue use of preservatives was observed in imported food. The sanitary regulation of the Port is being continually tightened up, for under the Infectious Diseases (London) Regulations, which came into force in 1927, while trench fever is no longer notifiable, induced malaria (if liable to relapse) must be notified four days before discharge from an institution to the medical officer of the district in which the patient intends to live, while enteric and dysentery carriers must be prevented from contaminating the food or drink of others. During the year 128 inspections of canal boats were made, one owner being fined £1 for not providing suitable heating aboard, and 200 new water-closets were provided in the area in continuation of a policy initiated four years ago.

A DIRECTORY OF THE LONDON HEALTH SERVICES.

A SERVICEABLE handbook, which contains information not so conveniently combined in any other work known to us, has been compiled by Dr. T. T. B. Watson and Dr. A. Welply, under the title of The Medical Signpost and Directory of the London Health Services, 1930.[1] The first part, about a quarter of the whole book, gives general notes, completely documented, on subjects which range alphabetically from Adoption Societies to Zymotic Enteritis. A description follows of the health administration of the 29 metropolitan boroughs, three or four pages being devoted to each. The information given about the boroughs includes the name and official address of the medical officer of health, and the facilities available in the way of hospitals, clinics, and convalescent homes; what diagnostic help is to be had and where the coroner and the relieving officers can be found; what charitable organisations exist and how their help can be enlisted and so forth.

A few pages at the end of the book are left blank except for headings under which practitioners are urged to provide notes for the use of locum-tenents. It frequently happens that the doctor whose practice is being taken over is unable either through illness or through absence to hand on information verbally to his temporary successor, and when the locum is not aware of the daily routine the practice must suffer. It is suggested that the practitioner who buys the book should at once fill in the details, so as to have ready prepared a list of practical points which may well be forgotten in the bustle of the change. The locum wants to know the methods of keeping accounts, the addresses whence nurses, drugs, instruments, and bottles are usually obtained, the nursing homes habitually used, the appointments held, the consultants whose advice is valued. The lay-out of the dispensary, the names of other doctors in the district, the fees charged and how they are collected, all these have to be passed on, and considerable time is saved if the locum knows exactly where to find instruments, throat swabs, and stationery forms. A blank sheet is left for a sketch map of the district.

We find singularly few omissions in any portion of the work. Such new ventures are mentioned as the Chelsea infant welfare centre for the professional classes, but no note is made of the centres where instruction on birth control is given by medical men and women. Among institutions devoted to cancer, the new Marie Curie Hospital appears, but not the Mount Vernon Hospital, Northwood; evidently the Parliamentary Act sanctioning the change in the objects of this hospital was not noticed by the authors, since two beds for tuberculosis at this hospital are still said to be allocated to the Borough of Hampstead. The list of the fees charged for pay-beds in various London hospitals are set out, also the procedure as regards medical fees and the extent to which the warded patient's practitioner can keep in touch with him. The days for attendance of out-patients in the special departments of the teaching hospitals will be appreciated. Altogether this is a useful compilation whose authors deserve the thanks especially of those practitioners who are newly resident in any district.

---

THE DIFFICULT CHILD AND THE TEAM METHOD.

THE difficult child has doubtless been with us as long as the poor, but has only lately been dignified with the title of a social problem. It is probably true that far more children are "difficult" nowadays than they were before the war. That conflict acted in various ways. Primarily it was, after all, only a gigantic symptom of psychopathic disease in the world's organism, the outward and visible sign of an inward problem to which the delicate psychological adjustments of the child are peculiarly sensitive. That disease is not yet cured. Secondarily, war meant that one generation of children was brought up under very abnormal conditions, often with little or no paternal influence and with a maternal element distorted by war work, privation, or anxiety. Thirdly, it made a profound difference in the outlook of the youth of the period, and their uncertainty in a tottering world is reflected in their children to-day. Those who recognise a very large and very grave "child problem" are divided in their views as to the best method of dealing with it. A method which has found much favour in America is the team method, or child guidance clinic, where psychiatrist, pædiatrist, psychologist, and lay social worker pool their efforts in an attempt to help the child to adjust to the reality of its environment. This was described at the recent discussion reported in our columns last week (p. 1261). American methods do not always suit this country, but the child guidance scheme seems likely to be of very great value if wisely and temperately organised and executed. The child guidance clinic at Islington was only opened this year, but has already proved its worth; the clinic at Clarendon-road, West London, has just issued its first annual report on 55 children referred to it for unmanageableness or other sign of disharmony with environment; and it is now five years since the Jewish Health Organisation inaugurated its splendid scheme, of which the outstanding feature is a Child Guidance Clinic at Spitalfields.

The past year in this clinic has—"fortunately," says the report—been free from dramatic developments, but has seen a steady progress towards more rapid diagnosis and greater facility in placing cases into their proper category for treatment. After the preliminary conference, a child is usually grouped in one of four classes: (1) for social investigation and social and familial correction or adjustment; (2) for educational and scholastic adjustment; (3) for personal psychological investigation by the psychiatrist; and (4) for joint activity of the whole clinic unit in association with any bodies interested in the case. The work then proceeds until the physician calls another conference for the coördination of investigation. The clinic had the courage from the start to reject hopeless cases instead of wasting its time and endangering its reputation by spending weeks on obstinate material too deeply buried in the social morass or too entangled in the meshes of constitutional defect to yield to an attack of any kind. The psychologists are agreed that cases are on the whole being seen too late; the majority of the children are between 11 and 12, and figures indicate that a large number of cases pass unnoticed until the problem reaches a sufficient degree of intensity to be remarked by parents or teachers. A poor physical constitution, it has been found, is a far graver factor in prognosis than a bad heredity, and the "backwardness" which appears so often in the complaint is far more often relative and emotional in origin than inherent. So far the work has been intensive and every case has been investigated with great thoroughness, but the clinic hopes in future to take another type of case for tentative advice and superficial study only, and thus to enlarge the scope of its work. Another project is to enlarge the waiting-room, with its stock of toys and books, into an elementary nucleus for occupation therapy. A ward for observation is urgently needed.

Another activity of the Jewish organisation is the supervision of evening schools, the hygienic conditions of which are often far from satisfactory. There seems to be a lack of appreciation of the serious dangers of insanitary and uncomfortable evening schools. Among other activities are research work, health education, and work for Jewish mental defectives. Dr. A. Sourasky is investigating the visual defects of Jewish boys and the incidence of cancer amongst Jews, and Dr. Emanuel Miller is to start an inquiry into the distribution of mental disorder among them. The Islington clinic is helped on its way by a grant from the Commonwealth Foundation in America, but the Council of the Spitalfields clinic feel acutely that their work is not sufficiently known to attract the funds they need and is yet so essentially personal and intimate that it cannot be advertised. The really difficult cases seen at the clinic, for instance, are too technical or unsuitable for illustrations, and those where the problems are superficial do not give a good idea of the arduous work or heavy expenditure involved. Their report is an extremely interesting document which should be read by all interested in the public health as well as by all members of the Jewish community. We shall look forward to the first report of the Islington Clinic next year.

PHENYLHYDRAZINE IN POLYCYTHÆMIA VERA.

THE value of phenylhydrazine in the treatment of polycythæmia was discussed at a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on Dec. 10th. A number of speakers testified to the value of this treatment, by which it is possible to reduce blood counts of eight or ten million red cells to normal levels in a few weeks. The technique usually adopted is to give capsules of 0·1 g. of the substance by mouth; the total dose, which is decided by observations of the blood count at frequent intervals, being usually not much in excess of one gramme. The ingestion of a gramme or more within a few days can produce toxic effects. Several observers had reported the incidence of jaundice, with bile-pigments in the urine, and an immediate direct van den Bergh reaction following treatment. But nothing more serious than a transient jaundice was observed by any speaker. As regards the general condition of patients treated with phenylhydrazine there was a general agreement amongst speakers that the giddiness, headaches, clouded intellect, and other common symptoms of polycythæmia vera, showed a notable improvement. Emphasis was laid on the fact that from the patients' point of view the method is much less disturbing than treatment by venesection or by irradiation of the bone-marrow. At the same time certain potential dangers must not be ignored. The toxic effects are probably due to hepatic poisoning, and in patients who have jaundice before treatment, further damage to the liver might easily prove serious. Cirrhosis of the liver has been known for many years to be an occasional accompaniment of Osler-Vaquez disease, and in its presence any drug with a toxic effect on the liver might be dangerous. Dr. L. E. H. Whitby drew attention to the frequent warnings in the literature that the appearance of a leucocytosis is a danger-signal during the administration of phenylhydrazine: in a series of experiments on animals he had failed to make any observations in support of this warning, *and in the cases reported at the meeting by Dr. Izod*

Bennett and Dr. D. T. Davies he had found that a rise in the white count ranging from 15 to 30 thousand was almost invariable, and did not indicate the onset of toxic manifestations. As regards the future of these patients, unfortunately the reduction in the red cell count was never more than temporary, although small doses of the drug given occasionally would keep the polycythæmia within reasonable bounds. Whether such treatment continued over a period of years will produce permanent damage to the liver is a question which present experience cannot answer.

THE M.R.C. AND GOOD ENGLISH.

THE lot of the writer of monographs is a hard one, for he must have done some hard thinking, and it is not made easier by the Medical Research Council which, in our view, imposes upon him salutary rules inspired by wisdom and experience. He is advised not to commence an article, he must begin it. He cannot have been engaged in a study of his subject; he has just studied it. He should not write in conjunction with a friend; but just with him. And he should not collect a considerable amount of material or a considerable number of facts, he should only collect much or many of them. In short, restrictions of liberty have been suggested, so that his manuscript will undergo a 20 per cent. reduction (or, as one might say, be one-fifth shorter) and eventually he may find himself writing quite good English without the help of the Publications Department of the Council. In the Notes upon the Preparation of Reports for Publication, which have just been issued in a revised edition after an interval of nearly nine years, the advice remains substantially the same except for the addition of two useful appendices: one of shorter and better equivalents for long words or phrases, the other a list of abbreviations of the names of journals taken from the World List of Scientific Periodicals prepared under the direction of the Keeper of the Department of Printed Books in the British Museum. The Notes have not been placed upon sale, but have been widely distributed among research workers in medicine. The advice is not oppressive or cramping to an author's style; by surrendering his liberty in non-essentials he will gain the freedom in essentials which really matters. The Notes are free from the touch of irony or subtle malice which seems almost incumbent on those who desire to impose their own literary style on others. It was a wise author who admitted the many ways of writing tribal lays every single one of which was right. The Council's censor has refrained from such banal quips as advising a would-be author to add a bibliography to his paper rather than a list of references and never to write the patient died but to say he ceased or "exitus lethalis." He might have said: If you feel the urge to write a medical article do not restrain yourself merely because you have nothing new to say and hardly know how to say it; facts and theories in medicine must be repeated again and again to drive them home. It is this sort of advice that estranges the earnest young writer and puts him off his stride when a more sympathetic mentor would be helpful in setting his feet on the narrow path of successful authorship.

Comparison of the Notes of 1929 with those of 1921 reveals one alteration for which we are profoundly grateful. In counselling the avoidance of obscure and misleading abbreviations the Publications Department has now fallen in with the continental practice of using the single letter g as an abbreviation for the gramme when standing alone or in its various compounds (kg., cg., mg.). Owing to the unfortunate similarity of the abbreviations used for the words gramme and grain these words should always be spelt in full if there is any possibility of doubt as to which unit is specified, but the Council has seen the wisdom of adopting the symbol g. for the gramme which is slowly but surely taking its place as the unit of weight throughout the civilised world. Rather singularly in doing so the Council has gone back on its abbreviation for cubic centimetre, which in 1921 was given as c.cm. and is now c.c., an exception to the rule made, it is stated, in order to conform with the general practice. But here, again, we feel that to make the exception is to introduce disorder into the very heart of exactitude. No doubt to those who are brought up in chemical laboratories a hundred-see-see measure or a ten-see-see bottle has become a habit of mind; to the chemist the see-see is the only unit, and the exception scarcely matters, but the biochemist has to do as much or more with the cubic millimetre, with its orthodox abbreviation. There can surely be no hardship or ambiguity in writing c.cm. and we trust that in this particular writers of monographs will assert their individual judgment against that of the Medical Research Council.

PSITTACOSIS.

IT is only recently that any real headway has been made in the investigation of the complex salmonella group of bacteria. It is now recognised that mankind shares infection by this group with a great variety of animals, and that the normal source of infection is the animal. A prominent member of the group, and a very widespread one, is *Bacillus ærtrycke*, which is often described under one of its very numerous synonyms. Among the rarer manifestations, at any rate in man, is the infection of parrots known as psittacosis, which seems to be transmitted from sick birds to man, and is held responsible for the recent death of Dr. D. L. Thomas, M.O.H. for Stepney.

In the latter part of the last century much attention was paid to the condition, especially in Paris and in Rome; a correspondent of THE LANCET in 1899 wrote with disgust of the hundreds of deaths from this disease in imported parrots, and in 1897 we published accounts of a number of fatal human infections in Italy. In Paris, in 1892, a real epidemic was recorded, with a case mortality of 45 per cent. Nocard, in 1893, recovered an organism from the bone-marrow of an infected bird, and Gilbert and Fournier, in 1896, from a human case, which has since been known as *B. psittacosis*, until it was recognised as the familiar *B. ærtrycke*. So recently as July 20th of this year Dr. A. P. Thomson reported in our columns a case in which the patient appeared to suffer from atypical fever, with a positive agglutination to *B. paratyphosus* B. She had nursed a sick parrot, and her little niece solved the problem of her illness by suggesting that "auntie has what the parrot had." From a developing parotitis (suitably enough) an organism was recovered which was stated to agglutinate slightly with paratyphoid B serum. Agglutination, however, does not seem to have been tested with *ærtrycke* serum, and the organism was at first described as Gram-positive. Three other less well-authenticated cases were recorded in the same district.

Many authorities deny that an infection is transmitted by parrots. To-day, at any rate, psittacosis is exceedingly rare in man, and, indeed, very uncommon in birds. At the London Zoo it is unknown, and it is possible that the disgraceful methods of transportation which our correspondent discussed in 1899 have to-day been abandoned, to the advantage of man and of parrot. The condition is so seldom met with that the diagnosis is scarcely one that should spring to the lips with confidence. The essentials in making out such diagnosis are a fulminating infection, with a positive agglutination to the salmonella group of organisms, the recovery of an organism of that group, and its identification with *B. ærtrycke*. If combined with the recovery of an identical organism from the incriminated bird such a history would be convincing. It is hardly necessary to add that the risk of contracting the infection from domestic parrots is remote, though it is probably wise to beware of such birds as develop an illness soon after importation into this country.

THE MEDICAL DIRECTORY.

THE new Medical Directory reaches us on Dec. 11th, well up to time. It is the eighty-sixth annual issue and the publishers have almost left off looking for new features, being as contented as are most of their subscribers with the present arrangement of the material. Graduates and licentiates in dental surgery, whose names were excluded from the Directory in 1925 to appear in a separate Dental Surgeons' Directory, are justified in regarding the discontinuance of this volume as a grievance. We do not know what may be felt by others who use the Medical Directory for constant reference—we have heard regret expressed for the omission of the year and the key-names at the head of the page—but the two inconveniences which we encounter with any frequency are the absence of private addresses under the heading of Naval, Military, Indian, and R.A.F. Services, and the absence of an alphabetical index covering the names in all seven sections. The latter might be rectified by a sudden act of grace in 1931 but the former might take long to achieve. The volume has increased in size by about 30 pages this year, owing principally to the inclusion of 391 more names. This annual increment, by far the smallest in the last ten years, is the net result of a profit and loss account, for the sections headed Scotland (−93) and Ireland (−120) have diminished, while those headed London (+48), Provinces (+304), Wales (+4), Abroad (+232), and Services (+16) have increased, although in unequal measure. We have given the actual figures in parentheses. It is, no doubt, time that the rate of increase did diminish unless new fields of medical practice are to be explored, for there has been the enormous increment of 10,257 names during the decade 1920–30, and obviously this could not go on safely. A special word of commendation might be given to that part of the introduction which treats of the health resorts of the British coasts and has been fully revised. An island may have its drawbacks, but it ensures a coastline sufficient to supply the needs both of its own workers and of visitors from other countries. The English littoral is estimated at 2350 miles, that of Scotland at 2300 miles, and of the British Isles at not less than 6000 miles, even were the circumventor to jump all the narrow creeks. We welcome the care and enterprise of the publishers in producing so valuable a work of reference. The publishers are Messrs. J. and A. Churchill and the price is 36s. net.

A NEW CAUSE OF INFLUENZA.

THE recent statement in the lay press that Prof. Falk, of Chicago, has discovered the cause of influenza in a pleomorphic streptococcus does not excite bacteriologists as much as it might have done 15 or 20 years ago. Many alleged causes have been discussed to the point of weariness and it has been realised that any such discovery would require long and searching criticism before it found general acceptance. In the first place, neither the definition of influenza in general nor its diagnosis in a particular patient are simple tasks. Under the convenient name of influenza are included illnesses with a very wide range of symptoms. The clinical recognition of such an indefinite disease is not beyond dispute, unless many synchronous cases occur in the course of a widespread outbreak which is comparable in type to previous acknowledged epidemics. The disease cannot readily, if at all, be recognised in animals, though monkeys, which are said to have been used by Prof. Falk for his experiments, appear to be the most hopeful subjects. The ætiological candidates for the position of causal organism in influenza pandemics have been many: they include Pfeiffer's bacillus, *Bacterium pneumosintes*, various streptococci, and an unknown filter-passing virus, which latter has of late claimed many adherents. None of these has established its claim, but all have much in their favour, especially in connexion with particular outbreaks or certain areas. It is possible that two or more infections may be associated in the same outbreak or even in the same case. The pleomorphism or uncertain morphology of Prof. Falk's micro-organism, which is said to resemble one described by Dr. D. and Dr. R. Thomson in our columns,[1] adds to his difficulties in establishing its importance, since irregularity in shape and size do not make for conclusive recognition. If his conclusions, based on the successful experiments which he is said to have made, withstand the criticism to which they will no doubt be subjected by other bacteriologists, bacteriology will be the richer for a micro-organism pathogenic to both man and monkeys, whose importance is in proportion to its prevalence. Whether the disease it produces is rightly called "influenza" is a problem which will require for its solution observations extending over a long time and a wide area.

THE house and library of the Royal Society of Medicine will be closed from Monday, Dec. 22nd, to Saturday, the 28th, both days inclusive.

AT a recent meeting of the Court of Assistants Lieut.-Colonel C. T. Samman, J.P., was elected to represent the Society of Apothecaries of London on the General Medical Council for one year, in succession to Mr. Samuel Osborn, who has resigned.

THE Royal College of Physicians of London will be closed for the Christmas vacation from Tuesday Dec. 24th, to Monday, Dec. 30th, both days inclusive.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. T. C. H. Neil to be Surg. Lieut.-Comdr.

The following appointment is notified: Surg. Comdr. J. F. Haynes to *President*, for R.A.F. and Medical Officers' Course, and to *Glorious*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub.-Lt. E. G. Thomas to be Surg. Lt.

Proby. Surg. Sub-Lt. H. E. Holling to be Surg. Sub.-Lt.

ROYAL ARMY MEDICAL CORPS.

Capt. E. P. N. Creagh to be Maj. (prov.).

Maj. J. Heatly-Spencer is apptd. a Professor, R.A. Med. Coll., vice Lt.-Col. W. P. MacArthur, vacated.

TERRITORIAL FORCE.

Capt. W. L. S. Cox, to be Divl. Adjt. 53rd (Welsh) Div., T.A., vice Maj. J. K. Holland, who vacates the appt.

Capts. W. Gault and W. B. A. Lewis resign their commns.

Capt. J. Rowland, from T. A. Res. of Off., to be Capt.

INDIAN MEDICAL SERVICE.

Lt.-Col. to be Col.: Bt. Col. E. A. Walker.

Temp. Lts. to be temp. Capts.—B. R. Bhaskar, H. K. Handoo, L. D. Sarronwala, P. N. Satho, D. N. Basu, H. S. Ahluwalia, M. N. Pal, and T. R. R. Pal.

Dev Datt to be Temp. Lt.

Maj.-Gen. R. W. Anthony retires.

A PROVINCIAL HOSPITAL FUND.—Sir Gomer Berry, High Sheriff of Bucks, last week opened two new wards of the Royal Buckinghamshire Hospital at Aylesbury. He suggested that a fund for provincial hospitals, similar to the King's Fund for London, should be established and that permission should be asked to call it King George's Fund.

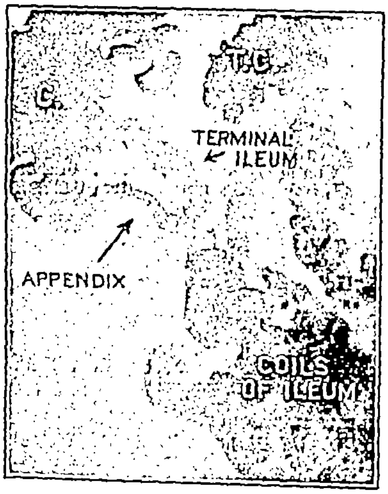
INTERPRETATION OF RADIOGRAMS OF THE ALIMENTARY TRACT.

PART IV.*—THE SMALL INTESTINE: THE APPENDIX.

ORGANIC lesions of the small intestine are, fortunately, rare. Symptoms are vague or absent and there are seldom any localising signs. Owing to the divided state of the food when it passes through the small intestine, it is liable not to be seriously delayed or obstructed till a comparatively late stage. Moreover, so far as my limited experience goes, there is little if any indication of spasm, and the lesions that have been found at operation have always shown marked organic narrowing. We depend for diagnosis entirely on the detection of a definite coil of intestine that is distended and in which we note peristaltic movements that fail to pass the opaque food onwards. By manipulation and palpation we attempt to isolate this coil and endeavour to note if the distal end of it is fixed, if there is any tumour, and so forth. If we note such a condition and find one end of the coil fixed, the diagnosis lies between adhesions, cicatrisation of ulceration, or growth. Apart from detecting the resistance of a tumour there are no guiding signs.

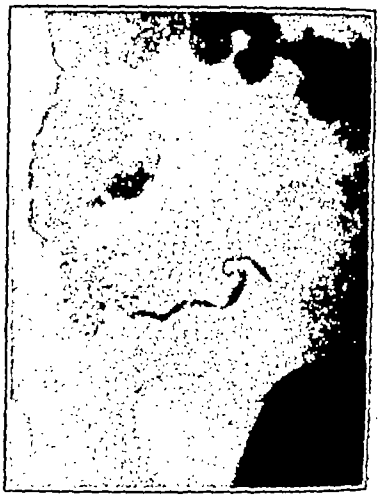
FIG. 21.



Condition of cæcal region when patient comes for examination on the second day, having been re-fed five hours previously. There is more food in the terminal ileum than normally on the technique employed and slight stasis. The cæcum is well filled and the appendix is of a large wide gauge type. No concretions noted in it. If the cæcum and appendix were freely movable and there was no pain on pressure on the appendix, this degree of stasis could well be overlooked. C = cæcum. T.C. = transverse colon.

When an obstruction is advanced, however, its presence is always indicated by the *fact that in our* preliminary examination in the upright position we note the appearance of a number of irregularly scattered air spaces in the abdomen, each with a horizontal fluid lower margin—like the air space in the stomach. Such a picture, *apart from* the effects of a purgative that is still acting, is certain information that we are dealing with an obstructive lesion in some part of the intestinal tract—perhaps even as low down as the rectum. Whether the radiologist should pursue his investigation and attempt to locate the lesion more than doubtful, for the condition is possibly already one of urgency so far as the intestine is concerned, even though the clinical picture is still vague and does not apparently call for urgent measures. The responsibility for pursuing the examination, which would necessarily entail delay, should be placed on the surgeon. In one instance known to me the surgeon, who operated at once, found an almost gangrenous length of gut in a patient who certainly presented no clinical evidence that such a finding was at all likely.

FIG. 22.



Appendix as seen 24 hours after food. On double feeding this appearance is often noted on the third day of the examination. Note the loaded condition of the rectum.

The detection of appendicular trouble depends entirely on the technique and experience of the radiologist. Given a standard technique, the radiologist can determine whether there is any delay behind the ileo-cæcal valve. If there is, it is of some importance. He should palpate the filled cæcum and terminal ileum; if he finds it to be abnormally fixed this also is of some importance. He may have to employ posture in addition to palpation in order to bring the cæcum out of the pelvis in certain cases. If in the course of his palpation he finds a definitely tender spot located to the site of the appendix it provides evidence of the utmost value. These three points—delay, abnormal fixation, and localised tenderness—taken together, if they are all positive, make an absolutely definite diagnosis of a chronic appendicular lesion. Tenderness localised to the exact site of the appendix is the one sign that is of conclusive value. The filling and visualisation of the appendix itself is not of great moment (Figs. 21 and 22). If we see it filled, we can palpate it and note whether it is free or fixed in the pelvis or elsewhere. but fixation of the appendix has not necessarily any present pathological significance. If the radiologist has the opportunity of observing the patient for some days, and finds that the opaque food is retained for a prolonged period, he is probably justified in saying that the appendix is not functioning normally. The longest period during which I have known opaque food to remain in the appendix is three weeks. During the game season, however, it is comparatively common to find shot, perhaps quite a number of them, lodged in the appendix for long periods.

The acute appendix is seldom seen in the X ray department. It gives rise to so much localised irritation that we find an empty condition in the cæcum and terminal ileum at a time when we should expect to find them filled. This appearance is suggestive, if not of a comparatively acute appendicular lesion, at least of some irritative condition in the cæcum or thereabouts. The appearance, however, is not at all uncommon in tuberculous disease of the cæcum, an infection that is comparatively rare apart from tuberculous disease in other regions.

SOME OBSERVATIONS ON SCANDINAVIAN SURGERY.

By T. HOLMES SELLORS, B.M. OXF.,

G. H. HUNT TRAVELLING SCHOLAR, UNIVERSITY OF OXFORD; SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

III.

SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS.

SANATORIUM treatment in Scandinavia differs little from the routine observed in this country, but in certain types of pulmonary tuberculosis surgical measures are far more freely utilised. All such surgical intervention may be classed as "Collapse Therapy," and the principles on which it is based depend largely on the extent and stage of the disease in *both* lungs. Immobilisation and rest are the ideal and essential features in the treatment of any form of tuberculosis, but in the lungs these are difficult to obtain. Furthermore, the contraction that should result from fibrosis during the process of healing is hindered by the rigidity of the chest itself. Apart from the local disease, the patient has to combat the general effect of the tuberculous toxin. His immunisation and resistance against this are admittedly favourably stimulated by sanatorium régime. The Scandinavians as a rule treat the exudative or progressive infiltrating forms on general lines, but find that the proliferative or fibrosing form requires further measures. Cavities may form and being unable to contract because of their peculiar situation in the lung tissue are secondarily infected; the patient's powers of resistance are diminished, and a troublesome cough inevitably follows. Collapse therapy aims at immobilisation of a part or the whole of one lung by assisting its natural tendency towards retraction. When the lung does retract, cavities are drained of pus and debris, and cough and expectoration soon relieved. The resulting diminution in the numbers of tubercle bacilli is an important social factor as soon as the patient returns to normal surroundings.

Before contemplating collapse of a lung the condition of the opposite side must be taken into careful account, for while one healthy lung is adequate for ordinary respiration, one slightly diseased may not be able to stand the strain thrown upon it when its fellow is out of action; its resistance to infection may be reduced. The set-backs consequent on incomplete retraction are also to be remembered; the risk of exacerbation in the uncollapsed areas of the affected organ is serious. The liability of the right side of the heart to embarrassment from pressure is another possible complication. Ideally the lung that is to officiate should be free from tuberculous lesion, but as this is rarely feasible every effort should be made to exclude the presence of the exudative form which is capable of giving rise to an acute and perhaps fatal broncho-pneumonic "flare."

The selection of cases really resolves itself into the estimation of the degree of activity of the disease in in the more healthy lung. Most dependence is placed on radiographical findings, but not to the exclusion of other clinical methods. Selection of the doctor to undertake the treatment is more difficult since an extensive surgical operation is outside the physician's sphere, and a surgeon may not be qualified to assess the general fitness of the patient and extent of the disease. In a few notable instances ideal coöperation obtains between physician and surgeon—Profs. Key and Jacobæus, of Stockholm, to wit. The alternative lies in complete control by a specialist in tuberculosis, like Dr. Gravesen of Vejlefjord, Denmark, who with a unique experience has complete control of treatment in all stages and forms of pulmonary tuberculosis. Before entertaining the procedures included in collapse therapy it must be realised that the patient's general condition is too often poor, partly as the result of the disease itself, partly from the absorption of toxins from secondarily infected cavities. The existence of tuberculosis in other organs, if mild, is not an absolute contra-indication, though each case has to be judged on its own merits as to what particular form of collapse therapy is to be employed and as to the fitness of the patient to stand the measures suggested. The patients themselves are generally willing to take a risk in the hope of an improvement that will raise them from their chronic unfitness.

In addition to the general indications for collapse therapy as have been mentioned there are also more urgent conditions, such as recurrent hæmoptyses, which may derive considerable benefit.

The operations included in the term collapse therapy are:—

Intrapleural—
- Artificial pneumothorax (A.P.).
- Thoracoscopy with division of adhesions.
- Division of adhesions by open operation.

Extrapleural—
- Phrenic evulsion.
- Extrapleural "plugging"—apicolysis.
- Thoracoplastic operations.

Artificial Pneumothorax.

The indications and technique of artificial pneumothorax in Scandinavian practice are very similar to ours, but its exploitation is more extensive both as a preliminary and as a supplement to some other form of treatment. Many authorities, notably Gravesen, hold that A.P. should be reserved for cases definitely demanding lung retraction, and not for early exudative disease, which would probably respond satisfactorily to sanatorium régime. The advantages of A.P. lie in the easy control of the process, so that re-expansion of the lung can be permitted when it is judged that the disease has been arrested or when there are signs of activity on the opposite side. In bilateral disease it can be used alternately or simultaneously, though care must be taken to leave sufficient healthy lung tissue available for ventilation. It can be said that all cases which may require pulmonary collapse should be started with an attempt at A.P., even though pleural adhesions are anticipated, since the estimation of these cannot be made until the pneumothorax has been attempted. The importance of adhesions is demonstrated by Gravesen, who quotes figures for advanced cases over 2–12 years, in which the capacity for work became 70 per cent. in cases without adhesions, whereas the percentage fell to 33 with localised and to 11 with extensive adhesions. The ease and elasticity of the treatment is somewhat countered by the necessity for "refills" which have to be performed every few weeks. Mobility of the previously fixed mediastinum may produce flutter and cardiac embarrassment, but adhesions with consequent fixation, if not already present, soon form after treatment has been started. Should the lung re-expand by accident or intent generalised pleural adhesions may obliterate the pleural space and prevent further injection of gas.

Thoracoscopy and Division of Adhesions by Cautery (Jacobæus's Method).

The presence of pleural adhesions is a serious drawback to the efficiency of complete artificial pneumothorax. A comparatively small strand may prevent collapse of the very spot that is maintaining infection. Division of selected adhesions may allow satisfactory collapse and maintenance of a complete pneumothorax. Gravesen's figures in A.P. illustrate the importance of adhesions as affecting the end-result, and show that thoracoscopy with division of adhesions allows 50 per cent. of the treated to return to work as opposed to 11 per cent. to 33 per cent. if the A.P. is continued in their presence.

This operation is regarded in most clinics as the routine precursor to a possible thoracoplasty in cases with an inefficient A.P. Thoracoscopy can be undertaken on out-patients for direct examination of adhesions, and is to be preferred to radiography, which may fail to give an accurate idea of their type and situation. Selection of those suitable for division is difficult, but the problem is more easily solved as the operator gains experience. Long cords give better results than short bands. Tissues other than pulmonary may have been pulled out of their normal site even into the adhesion itself, and jeopardise the success of the operation, perhaps even the life of the patient. The presence of lung tissue in an adhesion is a grave source of danger, for damage to a diseased area may produce an empyema with pleuro-bronchial fistula. Fatalities have been recorded from cauterisation of the subclavian vein, but dangers from adhesion stumps and intercostal vessels are negligible. Smoke frequently obscures vision, and has to be blown or sucked out of the pleural cavity.

Prof. Jacobæus, Dr. Gullbring (both of Stockholm), and Dr. Gravesen use this thoracoscopy with marked success, and in their hands the operation is delightful to watch. The technique, originated by Prof. Jacobæus, consists in the introduction of a wide trocar and cannula through an intercostal space near the site of an adhesion previously indicated approximately by X rays; the second or third spaces anteriorly or the highest space in the axilla are the usual locations. The tissues are thoroughly novocained, the instrument inserted, and an endoscope passed thereby into the pleural cavity, which can now be inspected for some distance. If, then, it is decided to divide an adhesion a second cannula is passed at the same level about 90 degrees further round the chest. A long, slightly hooked platinum electrode is then applied to the adhesion at a dull red heat, and division is accomplished under view through the endoscope. The cannulæ are similar so that endoscope and electrode are interchangeable, and access to the adhesion can thus be obtained from two points. Some degree of reaction and simple pleural effusion follow in most cases, and a certain amount of subcutaneous emphysema is almost inevitable, but these are of little consequence and A.P. can be resumed in a few days.

Division of Adhesions by Open Operation.

This is occasionally practised by Prof. Denk, of Graz, Austria, on selected cases. He is not a strong supporter of division of adhesions through the thoracoscope on account of the difficulties encountered, the long manipulation, and the risks of opening diseased lung tissue. The open operation can be performed under local anæsthesia with good exposure of the affected region.

Phrenic Evulsion.

Simple division of the phrenic nerve in the neck produces a temporary or partial paralysis of the diaphragm, but permanent paralysis can only be obtained by evulsion of as much of the nerve as is possible, so that the accessory branches (notably that accompanying the nerve to the subclavius) are included in the removal. Evulsion is the most satisfactory method of preventing regeneration of the nerve. The reduction in size of the thoracic cavity produced by elevation of the diaphragmatic dome is most apparent at the base of the lung, so that the lesions which respond best are situated in that region. A certain degree of improvement may accrue to cases with apical infection, but this is naturally dubious; the operation may, however, if performed at a lucky moment in an exudative process, prevent the formation of otherwise inevitable cavities. It does relieve paroxysmal cough of diaphragmatic origin, and give relief to some of the symptoms of pericardial adhesions.

Phrenic evulsion is certainly the most simple means of obtaining permanent reduction in pulmonary volume, and for this reason has been suggested as a termination to protracted A.P. treatment. Some degree of fibrosis and contraction must follow prolonged collapse of a diseased lung, and if cavities had been present before the collapse was undertaken the volume of the lung must have been considerably reduced. The lung re-expands on cessation of the A.P., and becoming adherent to the parietal pleura, tends to resume its original size. Were the chest wall sufficiently elastic to subside correspondingly, the end-result would be satisfactory, but where rigidity rules diaphragmatic ascent following phrenic evulsion will at all events give the lung less room to expand.

The indication and frequency of the operation vary with different authorities. Some use it as a preliminary to complete thoracoplasty with the object of revealing any undetected focus of tuberculous activity by a slight general reaction or of gauging the patient's behaviour towards the more serious experiment. Profs. Key, Denk, and Nyström reserve evulsion for basal lesions, and for a few cases in which thoracoplasty has not been entirely satisfactory. Dr. Gravesen uses it more as a preliminary to a thoracoplasty less extensive than that which most surgeons employ. Its comparative simplicity and ease make it valuable for the aged or debilitated consumptives, though its beneficial effects are small compared with those achieved by plastic operations of wider scope. Scandinavian teachers regard phrenic evulsion as an overrated procedure, with, however, a definite, if small, field of usefulness.

Local anæsthesia is always employed, and a short skin incision is made parallel to the posterior border of the sternomastoid muscle in the lower part of the neck, sometimes for cosmetic reasons, along the upper edge of the clavicle. The platysma and cervical fascia are divided, and the outer border of the scalenus anticus identified. The phrenic is seen running almost vertically downwards below the fascia, and may look surprisingly small. Novocain is injected into the nerve, which is then crushed and divided. The distal portion is seized with forceps and slowly twisted upwards. Deep-seated but not severe pain is felt in the chest, and occasionally a pain is referred to the shoulder. The nerve with its branches gives way or may be divided if about 10 cm. have been avulsed, though the length sometimes obtained reaches 25–30 cm.

Extrapleural "Plugging"—Apicolysis.

If pressure is exerted through the parietal pleura over a cavity in lung tissue it may have the effect of compressing it, so long as it is situated near the surface. Occasionally cavities in the region of the apex persist in spite of radical measures directed towards their collapse. In these cases it may be of advantage to apply extrapleural pressure by means of fat taken from the abdominal wall or paraffin "plugs," but these must be accurately placed if they are to be of any value. In addition it is not practicable to use plugging over a wide area.

The common indication for this type of operation lies in the persistence of an apical cavity following such a procedure as thoracoplasty. Once the cavity is accurately localised and shown to be sufficiently near the surface of the lung access may be gained by resection of the second rib anteriorly (Gravesen), or else by removal of the second, third, or fourth ribs posteriorly (Denk, Clairmont). The intact parietal pleura is then pushed down without injury over the cavity in the lung, and the space thus formed filled with the graft or plug. The superficial layers are carefully approximated.

Criticism is levelled against the operation on the grounds that the graft may not take, or that the plug may slough, and also that there is a considerable risk of infection from the subjacent lung. Rarely the plug has been known to migrate from its site as a result of imperfect fixation, but on the whole the results in selected cases can be distinctly gratifying. In other parts of the thorax plugging is a satisfactory method of obtaining adhesions as a preliminary to a transpleural operation.

Thoracoplastic Operations.

Several types of operation on the chest wall are in use, but the most common is the paravertebral (Wilms-Sauerbruch) thoracoplasty; the Schede and Estlander have been discarded. Anterior and lateral division of the ribs is employed only in cases where the paravertebral has proved inadequate. Failure of A.P. is the usual indication for the operation. It provides a permanent, rigid collapse and throws the responsibility of ventilation on the opposite lung for all time, and therefore should be reserved until the less drastic measures have been tried and failed. Total thoracoplasty is a severe operation, and should only be performed on patients whose general condition is comparatively satisfactory, and who show no signs of activity in the other lung, otherwise a fatal exacerbation is bound to ensue. About 40 per cent. to 50 per cent. are able to return to work within a year, and with judicious selection the results are really remarkable, since the majority have been operated upon more or less as a last resource when they are complete invalids. In Sweden, especially, thoracoplasty is regarded as a common surgical measure. Operation mortality is from 0 per cent. to 10 per cent. Failures and deaths are due to acute "flares" or gradual spread of the disease in the uncollapsed lung. The risk of right heart embarrassment in right-sided rib collapse has to be kept in mind. Should the thoracoplasty prove inadequate as a collapsing agent—as may happen with a very rigid apical cavity—supplementary rib resection or extrapleural plugging may be called for. Profs. Clairmont (Zürich), Key, Nyström, and Denk use a two-stage thoracoplasty; others prefer a single stage operation, which is bound to produce a severe degree of shock in an already debilitated subject, but which is free from the possibility of faulty rib-fixation which may occur if the interval between the stages is unduly prolonged. Partial upper thoracoplasty, often supplemented by phrenic evulsion, finds favour with Dr. Gravesen, but not with the above-mentioned surgeons.

Anæsthesia is generally local with the patient in a half-sitting position. Gravesen supplements local with light open ether and has no ill-effects therefrom. Speed is important, and if good collapse is to be procured, four to eight inches of the ribs must be removed right up to the level of the transverse processes. Division of the first rib is essential, and if possible an inch should be resected with due regard to the presence of great vessels and nerves. Prof. Key's resections are more extensive than those of other surgeons, and, with the exception of Prof. Nyström, resections are subperiosteal. All insist on the avoidance of any inward thrust or pressure during operation lest the parietal pleura be damaged, and the success of the whole proceeding endangered.

After-treatment is very important. The pain following the operation is severe and must be relieved. Sputum from cavities which are being compressed has to be evacuated, therefore coughing is encouraged, and the posture of the patient best arranged for that purpose. Sleep is necessary, but not at the expense of over-filled cavities. The object of the operation is attained when the mobilised ribs, having gradually fallen in and down towards the vertebral column, remain fixed against it. This may be assisted in the early stage by pressure with bags of shot, and later by some form of elastic belt. The resulting deformity is surprisingly small, and includes but a slight dropping of the shoulder with emphasis of pre-existing hollows. Scapular function is invariably excellent. Most surgeons who have performed this operation are impressed by its efficiency, and comment on the gratitude of patients who have been transferred from a state of chronic ill-health to comparative well-being.

MEDICINE AND THE LAW.

Doctor's Successful Appeal: Alleged Partnership Document.

A MEDICAL practitioner has successfully appealed against conviction in a recent case which, though lacking any special feature of medico-legal concern, is perhaps of general interest as showing how forensic and judicial irregularities can vitiate a criminal trial. The appellant was charged at the London Sessions some time ago with the larceny of stamps. In the course of his defence he had, as the lawyers say, put his character in issue. That is to say, he had claimed that his character was good and had put the fact forward as a reason why the jury should believe him innocent of the charge on which he was being tried. Now if, in defending himself, an accused person makes any positive assertion of his own good character or makes any attack upon the character of witnesses for the prosecution, he is liable to be cross-examined as to his credit. Under this rule the accused doctor was asked questions in cross-examination as to an alleged confession which it was suggested that he had signed, admitting dishonesty, on the dissolution of a medical partnership. He denied having made any such admission. The document was not produced to him though counsel for the prosecution seems to have displayed in his hands a paper which was visible to the jury. The accused man was pressed with a stream of questions about the alleged confession and, when some controversy arose as to whether the cross-examination was proper or improper, the jury—in spite of the protest of counsel for the defence—were asked to retire while legal argument was heard upon the point. This proceeding naturally tended to intensify the atmosphere of suspicion. The Criminal Procedure Act of 1865 lays down that a witness may be cross-examined as to his previous written statements without the writing being shown to him, but that, if it is intended to contradict the witness by the writing, his attention must first be called to the parts of the writing which are to be used against him. Apart from this specific statutory provision, the proceedings at the London Sessions seem to have been conducted with less than the usual fairness. In the upshot the accused man was convicted and was remanded in custody to the following sessions when sentence was passed to the effect that he be bound over for two years. The Court of Criminal Appeal found that three irregularities had occurred. In the first place, in cross-examining the defendant about the alleged document which was not produced, there had been a breach of a statutory rule. Secondly, in allowing the jurors to be sent out of court the tribunal had introduced an element of mystery and suspicion; indeed in the opinion of the Court of Criminal Appeal it is difficult to imagine any occasion when the jury could be asked to leave the box except at the request or with the assent of the defence while statements were made in their absence. Finally the judge at trial had summed up unsatisfactorily to the jury on the issue of criminal intent. For these reasons the appeal succeeded and the conviction was quashed.

It has befallen not a few medical practitioners to be mulcted in substantial damages for some alleged failure or mistake in the professional treatment of a patient. They will observe with envy that distressing mistakes can be made in the administration of justice without any liability being imposed upon judges or prosecuting counsel to pay any compensation whatever.

Suicide at Christian Science Home: Jury's Censure.

An inquest at Ealing on Dec. 14th upon a case of suicide at a Christian Science home at Greenford disclosed a difference of opinion between the jury and the coroner. The deceased woman was not a Christian scientist but was sent to the home at the instance of a relation who was presumably a Christian scientist and who had supported her financially; he explained to the coroner that he suggested her removal to the home as preferable to having her certified and sent to an asylum. The deceased's daughter stated that her mother had threatened to jump out of the window. When her mother was taken to the home her case was fully explained to the proprietress; it was then said that the windows were fastened. Next morning the deceased asked for some hot milk with her breakfast; as the attendant nurse went downstairs to get it, there was a call that someone was at the window. The dead woman had taken a chair from her bedroom and had climbed from it to the landing window. This happened at 9 A.M.; some 12 hours later she died from her injuries. Dr. M. H. Renall, in his evidence at the inquest, said that death was due to a compressed fracture of the spine. At 9.45 A.M. the daughter telephoned to the home and was told that her mother had passed a restless night and was being kept in bed; the daughter was not told of her mother's injuries till 11 P.M., when her uncle (the relative already mentioned) brought the news of her death. There was evidence that after her fall the deceased did not complain of pain or ask for a doctor, and that her injuries would have been difficult to detect without expert aid. There was also evidence that there had been no previous complaint of the conduct of the home; an attendant had slept in the same room as the deceased. The coroner summed up the case as one which might have happened in any home, and suggested that fault should not be found merely because the accident occurred in a Christian Science home. The jury, nevertheless, in returning a verdict of suicide during temporary insanity, added a rider that they accepted Dr. Renall's evidence that the dead woman must have suffered considerable pain and that they considered the proprietress guilty of neglect (1) for not taking any precaution to protect the deceased from the tendency of which she was made aware; (2) in not immediately calling a doctor; and (3) in omitting to inform the relatives at once of the occurrence. On these grounds they considered the proprietress of the home deserving of censure. The coroner dissociated himself from this verdict. It should be noted that earlier in the proceedings the coroner had asked the proprietress of the home, whether she would have called in a doctor if she had realised that the deceased had been badly hurt. The answer was "Yes." The proprietress had also explained that her husband was a trained medical attendant and had examined the deceased after the accident without finding any serious injury. This was not, therefore, it seems, a Christian Science home where the rules entirely forbade recourse to ordinary medical and surgical treatment. The incident indicates that, if the admission of mentally unstable persons to such homes is to be regarded as an alternative to skilled treatment in institutions provided or supervised under the Lunacy Acts, Parliament may have to pay attention to the consequent dangers.

THE LEAGUE OF MERCY.

THE Prince of Wales, Grand President of the League, took the chair at the thirtieth annual meeting of presidents, which was held at St. James's Palace on Dec. 11th. After reading a congratulatory message from the King, he referred with regret to the death of Lord Lambourne, a most valuable and enthusiastic supporter of the League. The new charter of the League, he said, would give it an opportunity of increasing the numbers of those serving on the council, and he mentioned that the ball held at Grosvenor House in June last had brought in a sum of £1535. Among the splendid contributions to the League during the past year was a donation of £1000 from Lady Melchett, while the gift of a League of Mercy film, the expenses of which had been borne by Mr. John Maxwell and Mr. Joseph Grossman, of the British International Pictures, Elstree, was greatly appreciated where it had been shown. Lady Tree's broadcast appeal had brought in £700.

The Voluntary System.

As a result of recent legislation affecting the health services of the country an attempt was being made by the county councils and county boroughs to bring all hospitals into close touch with one another, and it seemed clear that authorities still recognised the importance of retaining the voluntary system. It would be the privilege of the workers of the League to persuade people to open fresh districts for carrying on the work of the League. Only by this means could the ever-increasing financial demands of modern medicine and surgery be successfully supplied.

Financial Position.

Lord Cornwallis having been appointed chairman in place of the late Lord Lambourne, the Rev. W. H. Hornby Steer, deputy chairman, and the Rev. E. G. Gordon, hon. secretary, the members of the executive council were appointed, and presentations of the Order of Mercy were made by the Prince of Wales. Lord Marshall, the hon. treasurer, then made a statement with regard to the income of the League which had more than equalled last year's total. The income from collections amounted to £12,727, amounts promised to £11,373, while the estimate of amounts to come was £2300, making a grand total of £26,400, compared with £26,143 last year. A special donation of £1000 was given to the Thanksgiving Fund for the King's recovery, the donation to King Edward's Hospital Fund was £17,000, the same as last year, and the grants to extra-metropolitan hospitals amounted to £8300, making a total of £26,300, compared with £25,200 in 1928.

Lord Moynihan, in an address, said he welcomed the opportunity to express on behalf of the medical profession their profound respect and congratulations to the members of the League for all that they had done for the hospitals. There never was a time when hospitals were so well equipped and served by members of his profession, or were held so high in public esteem.

A vote of thanks to the Grand President and the Lady Grand President, to which Princess Mary briefly replied on behalf of her brother and herself, closed the meeting.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

National Health Insurance: Views of the Approved Societies.

THE annual meeting of the Approved Societies' Association of the Irish Free State, held last week, gave an opportunity for consideration and criticism, both of the present working of National Health Insurance and of the changes proposed in the Bill at present before the Irish legislature. The most important decision of the representatives at the meeting was a resolution stating: "That this Association is of opinion that a National Medical Service should be instituted in the Free State." This is the first time that the approved societies have given their support to the demand for a National Medical Service, as distinct from a demand for medical benefits. Hitherto, indeed, some of the societies have insisted that a system of medical benefits, if established, should be administered by the societies. That they have now adopted the policy supported and urged by the medical profession is a matter for satisfaction. The Association, in another resolution, again expresses its dissatisfaction with the present method of providing evidence of sickness, and states that "there is grave and increasing laxity on the part of certain medical certifiers in the issue of certificates of incapacity." The Association asks the National

Health Insurance Commission to take steps to remedy the present state of affairs, and to deal effectively with any medical certifiers found guilty of irregularities in the issue of certificates of incapacity. An increase in the number of medical referees is also demanded. Discontent was expressed with the proposal in the Government Bill to abolish insurance committees. It is clear, however, that in recent years these committees have had few duties to perform; their existence led to unnecessary duplication of work, unnecessary expense, and delay in providing treatment for insured persons. The Association is opposed to the expressed intentions of the Government to introduce legislation to facilitate, if not to compel, amalgamation of the smaller societies. One speaker expressed his opinion that there were only two ways of administering health insurance, either the present system or nationalisation. Another speaker drew attention to the high cost of central administration. Attention was drawn to the fact that the present Government Bill left all the main recommendations of the Report of the Committee of Inquiry untouched, and dealt only with a few of the less important. In contrast with this was the statement made last week in the Senate of the Minister for Local Government and Public Health that the Bill was intended mainly to give effect to the recommendations of the National Health Insurance Commission.

Chair of Surgery in the Royal College of Surgeons.

Mr. Arthur Chance was last week elected to the Chair of Surgery in the School of the Royal College of Surgeons in Ireland, left vacant by the resignation of Mr. A. A. McConnell. Mr. Chance is surgeon to Dr. Steevens Hospital, and Lecturer in Applied Anatomy in the School of Physic, Trinity College. He is a son of the late Sir Arthur Chance.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Libel Action.

A LIBEL action has arisen in connexion with a so-called "specific" against tuberculosis, which a layman claims to have discovered as a result of treating his own wife. The public press has given extravagant prominence to his claims with the result that patients in sanatoriums have become excited and upset. In one sanatorium the excitement rose to such a pitch that the patients rebelled against orthodox treatment and attempted to induce the medical staff to discontinue all other measures and substitute the new specific. Many half-cured patients have left the sanatoriums, with distressing results. A certain Dr. Nast, a physician of some standing, attempted to serve the public by publishing a pamphlet in which he explained the situation, showing no mercy to the inventor of the remedy. He asserted, and his findings appear to have received independent confirmation, that the "specific" was composed of cigarette paper soaked and crumbled. In the present state of the law Dr. Nast will probably be fined for libel since no one can deny that he called the inventor of the remedy a thief and a quack. The verdict will be pronounced next week, and it is anticipated that Dr. Nast will be let off as lightly as possible. It is also believed that the inventor himself may get into trouble for practising medicine without a qualification, which, I need hardly remind you, is illegal in my country although not in yours.

The Social Insurance Law.

A new social insurance law is to come into force on Feb. 5th and Parliamentary committees are now busy adjusting some of its provisions. Medical men have secured some important amendments of the original draft. As a result of protests fees will still be paid direct to the doctors and will be fixed by them according to their usual scale, the insured patient being awarded a round sum as an indemnity from which to make necessary payments. Free choice of doctor will be allowed, and the doctor will be at liberty to prescribe any drug except certain special ones. The selection of these has not yet been made, but it is probable that an official list of authorised special remedies will be compiled, similar to that in use for medical work under the poor-law. If the proposed law gets through both Chambers in its present revised form it will involve but little change in current medical practice.

A New Faculty of Medicine at Marseilles.

Marseilles is the second largest town in France, with a population of about a million. Up to now it has had only a "school" of medicine; that is, students could only take part of their course there and had to go for nearly all their examinations to another town. Generally they went to Lyon or Montpellier—where there are faculties of medicine, though Montpellier has hardly 100,000 inhabitants. Jealousy between the neighbouring towns has hitherto prevented the development of the medical school of Marseilles, but since at such a big port an extraordinary variety of diseases may be observed it is satisfactory to learn that university status has now been achieved. The faculty at Marseilles will develop the department of tropical medicine and pathology, and it is hoped that in the course of a few years it will become an important centre for teaching and research.

Stationary Cars in Paris.

An automobile club of doctors has been started in Paris under the presidency of Prof. J. L. Faure. The first object of the club is to settle with the prefect of police the question of leaving cars in streets. A half-hour limit is shortly to be enforced in the main streets of Paris, and the members of the club hope to secure exceptional treatment for cars belonging to medical men.

Dr. Charles Nicolle, head of the Institut Pasteur of Tunis and winner of a Nobel Prize for Medicine, has been made a member of the Académie des Sciences, of which he was already correspondent. Prof. Lépine, Dean of the Faculty of Lyon and member of the Académie de Medécine, has been elected corresponding member of the "Académie des sciences morales et politiques" in the section of philosophy. He is professor of clinical neurology and psychiatry. Prof. Gosset will be this year's chairman of the National Society of Surgery. Dr. Lhermitte will be the chairman of the Society of Neurology, and Mr. Tissier will preside over the Society of Forensic Medicine, which has a mixed membership of doctors and lawyers.

MILLER GENERAL HOSPITAL, GREENWICH.—At the annual meeting of this hospital last week it was stated by Lord Queenborough, the President, that the response to a recent appeal had been only five shillings. The income has gone up by £5000, but the expenditure has increased to an even greater extent, and there is a net deficit on the last two years of £1360. During the year patients' payments amounted to £2707.

THANK-OFFERING FUND.—This Fund, which has now been closed, amounts to £680,507. Out of the money subscribed for the purchase of radium £100,000 has already been paid to the National Radium Trustees to enable them to claim the equivalent Government grant and a further £50,000 has yet to be handed over. "Audax's" donation of £105,000 to King Edward's Fund is being invested and the income will be used to swell the amount available for annual distribution. A balance of £37,000 subscribed for radium will be given to the King's Fund for the purchase of radium to be lent to the London hospitals. The King's Fund will make a special distribution in aid of extensions of and improvements to hospitals. The donations received before August 1st earmarked for individual hospitals have been paid over, and the balance is now being distributed. The number of separate distributions has amounted to nearly 500.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1928 statistics of four large towns, which suffer excessively from atmospheric pollution, and of two smaller towns more favoured in this respect. The variations in the rates of young child mortality are striking.

Name of town and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Manchester .. (767,530)	16·8	12·9	1·29	1·44	2·6	1·5	91/34	44	4·1
Newcastle-upon-Tyne (281,500)	19·2	13·1	1·32	1·54	1·8	1·9	83/38	44	5·0
Salford .. .. (241,500)	16·9	13·3	1·42	1·32	3·2	1·3	106/—	48	4·2
St. Helens .. (110,600)	21·8	12·0	0·95	1·09	2·5	1·6	98/48	50	4·6
Poole .. .. (52,940)	17·3	11·9*	0·77	1·42	1·8	1·5	50/30	24	8·7
Colchester .. (44,880)	15·8	10·5	0·69	1·80	0·9	1·7	42/—	17	1·3

Relation of stillbirths to live births: Manchester 6·2 per cent., Newcastle 6·1 per cent., Salford (those notified) 5·0 per cent., St. Helens (notified) 4·4 per cent., Poole, 2·7 per cent., and Colchester 3·9 per cent. * Standardised rate 10·0.

Manchester.

Dr. R. Veitch Clark reports that the infant mortality-rate was five higher than in 1927 and four higher than in 1926. The increase was chiefly due to the later persistence of diarrhœal and wasting diseases during the fourth quarter and to the prevalence of whooping-cough, and a definite outbreak of acute respiratory catarrh in the city during the same period.

A special report on diphtheria immunisation made to the city council in June shows that during the ten years 1917–26 there was a yearly average of 758 cases of diphtheria with 69 deaths, and that half the deaths occurred in children under 5 years and 96 per cent. of the deaths in children under 15 years. The case fatality of Manchester children who have contracted diphtheria during this period has been 10·5 per cent. The cost to the municipality of providing treatment for this disease is estimated as being nearly £14,000 for 1926 and £9000 as an annual average. Examples are given to illustrate the benefits of immunisation schemes in other places, and it is mentioned that in Monsall Hospital no fully immunised member of the nursing staff has developed diphtheria since immunisation was adopted in 1925. The city council, as the result of the report, approved a scheme for the free provision of the necessary material for immunisation to medical practitioners and hospitals and for the carrying out of immunisation through the maternity and child welfare centres, school clinics, &c. Towards the end of the year a beginning was made and 490 immunisations were carried out at the child welfare centres.

The cases of encephalitis which came to light during the year numbered 50, of which 17 began to be ill in or prior to 1926, 11 in 1927, and 22 in 1928. The deaths caused by this disease numbered 41, 17 being those of persons notified in previous years. Children suffering from post-encephalitis are fairly well provided for by the guardians in Swinton Home. Adults who are bedridden and only require nursing care are provided for in the poor-law hospitals, but there remains a group of patients from the age of 14 years upwards, but mainly adolescents, for whom at the present time there is no suitable provision. This group largely suffer from moral defects or milder degrees of parkinsonism, and a scheme for their benefit is being considered by a joint committee of the health and education committees and the guardians.

The registration of stillbirths came into force on Jan. 1st, 1928. The principal causes of stillbirth in 130 cases investigated in the practice of midwives were: albuminuria of pregnancy 23, breech presentations, 24, antepartum hæmorrhage 11, and twin pregnancies 8. The attendances at the antenatal clinics showed an increase from 2746 in 1927 to 4800 in 1928. The ten clinics were attended by 1711 new cases, while the total births were 12,909. The cases of puerperal fever and pyrexia which ended fatally numbered 29, of which 8 were cases of abortion and 4 came from outside districts. The particulars are given of 45 other maternal deaths investigated, and if these are added to the 25 deaths from sepsis the maternal mortality from childbirth becomes 5·4. The admissions to the Monsall Hospital puerperal fever ward numbered 154, of which 21 ended fatally, but 6 died within 48 hours of admission. Dr. D. S. Sutherland states that septicæmia has not been found difficult to treat provided the focus of infection can be successfully dealt with by repeated glycerin-iodine intra-uterine injections. The intramuscular injection of metarsenobillon has given promising results when the septicæmia is treated early, and it is hoped to give in the 1929 report sufficient evidence as to its efficacy or otherwise. Dr. Clark reports that handicraft work has been developed at Baguley Sanatorium, and that good progress has been made in the building of the new children's sanatorium at Abergele. An increase is noted by Dr. D. P. Sutherland (tuberculosis officer) of the notifications of pulmonary tuberculosis between the ages of 25 and 34 in both males and females, and of the deaths at the same age-period only among the males.

Artificial light treatment is thought to be an advantage to the child in-patients at Abergele, but Dr. Sutherland is much more doubtful as to the benefits of light treatment given to out-patients. For lupus it is undoubtedly a benefit; but in other varieties of non-pulmonary tuberculosis the results are often indifferent. On the other hand, the use of artificial light for the treatment of children selected from the different maternity and child welfare centres and suffering from rickets, malnutrition, and debility following illness, is thought to give good results when the attendances are regular. Benefit is also claimed in the case of children suffering from adenitis, asthma, and nervousness, and of nursing mothers with failing lactation.

There were several introductions of small-pox by tramps and 68 cases in all with no death. Eleven cases of bacillary and two of amœbic dysentery were notified. The Flexner bacillus was responsible for seven cases and the Sonne bacillus for four. A boy of 3 years died from Sonne dysentery. Of the amœbic cases, both contracted in Mesopotamia during the war, one, aged 48, died. Early in the year there was an outbreak of ergot poisoning in North Manchester. The first cases occurred in private practice and one of the hospitals. The number of persons affected is unknown and it is not mentioned how severe the cases were. The use of the ergot-infected rye was prohibited and its sources investigated. The Ministry of Health has continued the inquiry and taken action to prevent the recurrence of the trouble. The new cases of syphilis and gonorrhœa treated were about the same as in the previous year. About one-quarter of those treated failed to complete the treatment up to the final tests. The use of antitoxin for the treatment of scarlet fever is being extended at Monsall, and it is estimated that the duration of stay in hospital can be thereby safely shortened by about seven days. Hitherto the serum has been injected intramuscularly. It is also being used for the immunisation of diphtheria cases admitted. The bed-isolation ward at this hospital has proved extremely useful, 317 cases of various illnesses having been admitted without any case of cross infection. Pemphigus neonatorum is notifiable in Manchester. Among the 106 cases reported there were 58 of infants under 11 days old and the total deaths numbered four, two being in institutions. Except for one outbreak of 22 mild cases in the same practice, the majority were isolated cases.

The city farms accommodate 951 cows, and amongst these one tuberculous udder and two cases of pulmonary tuberculosis (not advanced) were found. The percentage of tuberculous country milks was unusually high—viz., 694 samples with 122 tuberculous, or 17·6 per cent. Of 102 Derbyshire samples, 24·5 per cent. were tuberculous; of 348 Cheshire samples, 18·1 per cent.; of 101 Staffordshire samples, 16·8 per cent.; and of 110 Lancashire, 10·0 per cent. The regional smoke abatement committee has interested itself especially in standards for smoke emissions, by-laws, and the provision of solid smokeless fuel. The Manchester Committee on Cancer has attained some success in discovering a method for producing a purified oil which is non-carcinogenic and therefore safe for industrial use, whilst its lubricating power is unimpaired.

Newcastle-upon-Tyne.

Dr. Harold Kerr reports that in spite of trade depression, increased unemployment, and much demand for assistance from the guardians, the infant mortality and tuberculosis death-rates were lower than ever before—a tribute to the efficiency of the relief organisations. The hours of sunshine recorded at Armstrong College were 1109 as compared with 899 in the previous year. The city only has three-quarters of the sunshine available in the neighbourhood. A comparison shows that the deposit from the atmosphere in the residential district of Westgate Hill contains 3 per cent. of tarry matter and 50 per cent. of ash, whilst the deposit at the quayside contains 2 per cent. of tar and 66 per cent. of ash, indicating more complete combustion in the industrial area. Dr. Kerr deplores the high cost of the smokeless fuels on the market, and evidently Newcastle lacks the advantage of the dry coke from vertical retorts available in Salford. The behaviour of the corporation chimneys has improved, and a satisfactory smoke prevention apparatus has been installed at the new baths. The tramways chimney has substituted the emission of grit for that of dense volumes of black smoke. The attempt to form a regional smoke abatement committee has temporarily failed owing to apathy and indifference or to the jealousies of neighbours. There were 76 cases of small-pox, all of the mild type, though two of the male patients, aged 60 and 69, died from cancer.

During the year bacillary dysentery was recognised in the city. The first indication of its presence was the occurrence of five mild cases in a house in Cowgate during March. Prior to bacteriological examination food poisoning was suspected. In April two sudden deaths of children were investigated by the coroner and found to be due to "bacillary dysentery." The medical practitioners of the city were notified. In all 66 cases, six of which came from outside, were brought to notice and the majority were treated in the city hospital. There were ten deaths, two at the age-period 1 to 5, seven at the age-period 5 to 15, and one over 45. Eight of the deaths were of females, two of males. The outbreak was peculiar in that five types of the Flexner bacillus, the Sonne bacillus, and a newly isolated germ (the "Newcastle bacillus") appeared to be the causal organisms. An unusual occurrence was an outbreak of poisoning among the employees of a firm. The management provided lemonade during the hot weather which was mixed in enamelled buckets. The illness was caused by tartaric acid releasing antimony compounds from the enamel which was not of a high quality. Fifty-six patients were removed to the Royal Infirmary, but most of them were able to resume work after some hours and none of them showed after-effects.

The duration of stay in hospital for scarlet fever has been considerably shortened by the use of antitoxin and also by the work of the oto-rhinologist. The average stay for scarlet fever patients was 29·3 days, and the return case-rate 1·3 per cent. Since protective inoculation was adopted for scarlet fever, diphtheria, and enteric fever there has been no case of any of these diseases among the hospital staff. Newcastle has generally had a smaller maternal mortality than the rest of the country, but during 1928 the rate jumped up to 4·97 and the death-rate for puerperal sepsis (1·66) was more than double that of the previous three years. About a quarter of the mothers attend the antenatal clinics. Dr. Kerr suggests that a consultant's opinion ought to be made available for confinements generally and not only in cases of puerperal fever, and that sufficient use is not made of the sterilised outfits on sale at the antenatal centres. Of 376 samples of milk examined for tubercle 3·7 per cent. were positive, but the endeavour to track out the infecting animals at the 11 Northumberland farms implicated was not very successful. The condition of the water of the swimming baths provided with a continuous system of filtration and aeration is much superior to that of the baths the water of which is changed twice or thrice a week.

The chief sanitary inspector, Mr. C. Raimes, describes the efforts made to effect a reduction in the number of van dwellers and the difficulties created by the lack of low-rented houses. For example, in the hearing of an application for ejectment orders, the rent of the tenants was 4*s.* per week and the alternative accommodation offered 11*s.* to 12*s.* a week.

Salford.

The headquarters of the public health department, 131 to 155, Regent-road, with some of the ground floor shop windows used as health exhibits, forms the frontispiece of Dr. H. Osborne's report. In this block are housed the public health and school staff, the public analyst, the bacteriologist, the tuberculosis dispensary, the new municipal V.D. clinic, and the new artificial light clinic. Up to March 31st, 1928, the V.D. clinic was conducted at the out-patients' department of the Salford Royal Hospital. On April 1st the work was transferred to the municipal clinic, and the first nine months' working have falsified all the theoretical objections to an ad hoc clinic. The premises have been specially equipped; there is a whole-time staff; the clinics are held more frequently and at convenient hours, and intermediate treatment is available daily for both sexes for a total period of 71½ hours weekly. As a result there has been a very large increase in the attendances since the transfer, and steps are being taken to still further perfect the methods adopted. Two new maternity and child welfare centres are being established, and the decision to have an out-patient light centre is based upon the excellent results obtained at the municipal babies' hospital.

Two health weeks were held from Dec. 2nd to 15th, and a health exhibition which attracted 30,000 visitors. A feature of the exhibition was a demonstration of "vertical" coke and other smokeless fuels burning in fire-brick grates. In order to remove doubt in the public mind as to whether Salford vertical coke is suitable for heating an oven Dr. Osborne has carried out experiments which demonstrate that this fuel is entirely satisfactory for the purpose. He points out that the supply of such fuels is still very limited but is certain to increase as the public demand grows. He would like all gas undertakings to consider the vertical retort when they are making new installations, and he makes a wide distinction between dry gas coke and the ordinary wet gas coke. He points out that the deposit from the atmosphere contains much more tar in Salford than it does in Birmingham, Glasgow, and Leeds, as one would expect in "a working-class dormitory city packed with small dwellings having open ranges burning bituminous coal." There are only 100 cows kept in the city and amongst these the veterinary inspector found two cows with clinical tuberculosis and one with tuberculosis of the udder.

Of 445 "outside" milks examined 37 were tuberculous. Cheshire milks always come out worse than Lancashire. Of the 37 incriminated farms, 10 had one cow with tubercle of the udder, 7 had two, 1 had three, and in the remainder no cows were found affected. In several of the latter cases the owner admitted that a cow which was wrong in the udder had been disposed of after the sample had been taken.

The public analyst, Mr. H. H. Bagnall, describes the shortcomings of the new Food and Drugs Consolidation Act which came into force on Jan. 1st, 1929. He also refers to an unusual feature in the milk samples taken during the first two quarters of 1928. Many samples from many farms were low in non-fatty solids, and this phenomenon followed on an extraordinary rise in the percentage of fat during the last quarter of 1927 which continued during the first quarter of 1928. Two noteworthy successful prosecutions are described: one for selling factory-made "lemon cheese" (not made from butter, sugar, eggs, lemon juice, and rind) as "home-made"; and the other for the sale of cod-liver oil tablets from which vitamins A and D were entirely absent.

St. Helens.

Dr. F. Hauxwell's report conveys the impression of a very efficient public health medical service working for the individual. He describes the year's work of a real antenatal clinic, not one of the non-medical or social type, but conducted by a doctor with a view to detecting abnormalities and making appropriate arrangements for a safe confinement. This scheme has been helped by the provision of the new maternity block at St. Helens Hospital and will be still further strengthened by the proposed municipal hospital for 15 maternity cases and 24 children. The orthopædic scheme has proved successful in getting in touch with cripples at an early stage. During 1928 the orthopædic surgeon, Mr. T. P. McMurray, had under his charge 40 cases of tuberculosis, 165 children under 5 and 105 non-tuberculous school-children. A considerable number of these children received in-patient treatment in the Liverpool and Wirral hospitals. Dr. Hauxwell notes that after the post-war years there was a distinct fall in the new cases of venereal disease attending the clinic, but that since 1922 there has been a steady increase up to 1928, most marked in gonorrhœa. Increased popularity of the clinic would hardly account for the figures being nearly doubled in six years. Cases, however, attend earlier and more regularly than formerly. The investigation of maternal deaths shows that if all the deaths associated with child-birth are reckoned with the maternal death-rate becomes 7·1 per 1000 live births instead of 4·6.

During the months February to May milk samples were unusually poor. Of 141 samples only 94 were above the low standard of the regulations. Poor quality of hay was alleged as a cause and the quality improved when the cattle were turned out to pasture. The chief industries of St. Helens are coal-mining and glass-making, and a table shows that St. Helens compares unfavourably with London, Birmingham, Cardiff, Huddersfield, Rotherham, and Wakefield as regards the amount of dirt deposited from the atmosphere. Only one of the stations in Newcastle-upon-Tyne is shown as giving a worse result. Dr. Hauxwell has many complaints to make with regard to environmental hygiene. The rivers and streams are seriously polluted with sewage; over 1200 privy middens and pail-closets need conversion; the refuse tip causes an unnecessary nuisance; and there is urgent need for the provision of smaller and cheaper houses in order to cope with overcrowding.

Poole.

Dr. R. J. Maule Horne reports that owing to the erection of new houses in outlying districts cesspools have increased from 400 in 1926 to 783 in 1928. It is hoped that 325 of these houses will be caught up by sewer extension during 1929. Endeavours are being made to select a better refuse disposal system than the existing tips. The open-air tidal swimming bath on the foreshore is well used during the summer, and a new sea-water swimming enclosure is to be provided in the public park. Mosquito control, by spraying the lakes and ponds with paraffin, has been continued. Oysters dredged from the harbour have to be relaid for 14 days in the Shipstal beds and the bacterial tests periodically carried out show the dependability of the relaying process. During 1927–28 50,000 oysters were dredged, but owing to two cold spatting seasons the number has now to be reduced to 25,000. Dr. Horne conducts the antenatal clinics, which are closely coördinated with the maternity department of Cornelia Hospital, where another antenatal clinic is held for the mothers, who await admission to the wards, by the obstetrician who will attend them.

Colchester.

Dr. W. F. Corfield shows how the deaths of children under 5 have decreased in recent years. During 1928 17 of these children were nursed by the district association when ill. An antenatal clinic was started in March and Dr. Grace G. Griffith, of Bures, was appointed (part time) medical officer in charge. For the first nine months the new patients attending numbered 71. The Ministry did not approve the two houses suggested for conversion into a maternity home and it seems probable that this long-delayed scheme will await the imminent changes in the poor-law. The orthopædic clinic conducted by Mr. B. Whitchurch Howell dealt with an increased number of cases, and many deformities are being treated before they have had time to do serious damage. As in the case of Poole building in outlying districts has caused an increase in the number of cesspools—and in addition of private wells. In August there was an outbreak of enteric fever in a mental hospital. Full investigation threw suspicion on the food, and the cause was considered to be infection by a member of the kitchen staff, who had, a short time previously, suffered from an indefinite attack of illness. None of the staff was affected, but there were 81 cases among the patients with 28 deaths.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 7TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 252 (last week 198); scarlet fever, 3388; diphtheria, 1743; enteric fever, 54; pneumonia, 1253; puerperal fever, 57; puerperal pyrexia, 100; cerebro-spinal fever, 7; acute poliomyelitis, 9; acute polio-encephalitis, 2; encephalitis lethargica, 19; continued fever, 1; dysentery, 10; ophthalmia neonatorum, 95. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Dec. 10th–11th was as follows: Small-pox, 353 under treatment, 15 under observation (last week 308 and 10 respectively); scarlet fever, 2745; diphtheria, 2008; enteric fever, 70; measles, 501; whooping-cough, 123; puerperal fever, 23 (plus 12 babies); encephalitis lethargica, 123; poliomyelitis, 0; "other diseases" 12. At St. Margaret's Hospital there were 12 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns including London there was no death from small-pox, 2 (1) from enteric fever, 27 (10) from measles, 10 (4) from scarlet fever, 19 (2) from whooping-cough, 43 (5) from diphtheria, 45 (10) from diarrhœa and enteritis under two years, and 53 (15) from influenza. The figures in parentheses are those for London itself.

The death from enteric fever outside London was reporte from Hull. The highest figures for diarrhœa were fro Manchester 5, Liverpool 4. Measles claimed 4 deaths Wigan, whooping-cough 3 deaths at Liverpool, diphthe 5 deaths at Liverpool, and 3 at Merthyr Tydfil. The number of stillbirths notified during the w was 244 (corresponding to a rate of 40 per 1000 births), including 39 in London.

Correspondence.

"Audi alteram partem."

TREATMENT OF CAVERNOUS NÆVI.

To the Editor of THE LANCET.

SIR,—On p. 1251 of your last issue Dr. G. B. Dowling advocates the treatment of cavernous nævi by injections of quinine and urethane. In the course of his remarks he says that surgical excision "is undesirable in an infant and in some situations impossible." I am not here concerned with the proposed substitute, but it is surely time that the profession as a whole realised that the excision of a nævus is one of the most satisfactory little operations in the surgery of childhood. Time is a most important factor. Nævi which at birth are a few millimetres in diameter often grow at an appalling rate. Excision becomes impossible and the electro-cautery is quite properly used. This is often successful, but a matter of moments has become a matter of months and the hapless child is branded with a pock-marked area of lepra-like integument. The early doors of a children's hospital are besieged by pathetic sufferers *from spina bifida, syndactyly, and hypospadias*, while lanugo yet lingers on their brows—but the cavernous nævi stay at home and wait for the warmer weather.

Admittedly, excision of nævi in some situations is impossible from the beginning, but the impossibility is as often caused by procrastination as by position. If we must have a slogan let it be "a nævus excised is a tragedy averted"—and the earlier the easier.

I am, Sir, yours faithfully,

Wimpole-street, W., Dec. 16th, 1929. ERIC I. LLOYD.

IRRADIATED MILK *v.* COD-LIVER OIL FOR RICKETS.

To the Editor of THE LANCET.

SIR,—May I reply to Dr. Bodman's letter in your issue of Dec. 7th? My opinion of the very low antirachitic potency of non-irradiated milk is based on the examination of 11 different samples, of which five were bought in the open market and six were sent from the makers of the irradiated milks for comparison. The method of testing for vitamin D adopted in these laboratories is Mr. Collum's "line" test, a method frequently described in the scientific literature on the subject and adopted by most laboratories in Europe and America. By assaying the antirachitic potency of any substance in terms of our standard preparation of irradiated ergosterol (described in the *Quarterly Journal of Pharmacy*, 1928, i., 27) it has been possible to collect and compare figures for the antirachitic activity of substances over a period of nearly three years.

The examination of 11 samples of fresh milk showed negligible quantities of vitamin D in seven samples, 0·1 unit per gramme in one sample, and 0·2 units per gramme in three samples. The vitamin D potency of non-irradiated milk appears to be particularly low when it is compared with the vitamin A potency, a comparison which may be drawn in two ways. When rats have ceased to grow on a diet deficient in vitamin A which, according to Mellanby, is a direct result of the development of various pathological conditions, 1 c.cm. of milk given daily will almost invariably cure these disorders and growth will be resumed. On the other hand, when rats have developed a severe degree of rickets on a rachitogenic diet (deficient in vitamin D and with a Ca : P ratio *of 4 : 1), 1 c.cm. of milk daily gives no indication* of healing; in fact one sample of milk produced no healing in a dose of 20 c.cm. daily. While the different conditions of the rats given on the one hand no vitamin A, and on the other no vitamin D cannot be considered exactly similar, yet they afford a useful basis for a practical comparison of the respective *amounts of vitamins A and D in milk*. The comparison may also be drawn by reference to the vitamin content of cod-liver oil. A fairly good sample of cod-liver oil will cure the disorders resultant on a deficiency of vitamin A and promote good growth by means of a dose of 0·01 gramme daily. The same dose of cod-liver oil will *completely cure* a very severe degree of rickets. Thus it may be said that an average sample of milk has about one-hundredth of the vitamin A content of our average sample of cod-liver oil. It has, at the most, one five-hundredth of the vitamin D content; one sample examined had less than one ten-thousandth.

In Sherman and Stiebeling's experiments I would point out that the inclusion of 5–10 per cent. of dried milk in the diet of rats on whom the experiment was performed would ensure that the rat ate about 0·5–1·0 gramme dried milk per day. Assuming 12½ per cent. dry matter in milk, this would be equivalent to 4–8 grammes fresh milk per day, which would doubtless be sufficient of *some* samples of milk to afford protection from rickets and promote growth in rats, especially when the basal diet is, as stated, adequate in all other respects including mineral content. These results are not "quite opposed to" our own, as Dr. Bodman thinks. They confirm them by emphasising the large amount of milk necessary *to protect rats from rickets even when the rest of the* diet is as nearly perfect as present knowledge can make it.—I am, Sir, yours faithfully,

ENCEPHALOMYELITIS FOLLOWING VACCINATION.

To the Editor of THE LANCET.

SIR,—*Dr. C. D. Coyle and Dr. E. W. Hurst close* their interesting article on this subject in your last issue with the words: "Any investigation must . . . aim at discovering a common factor responsible for the production of identical histological lesions in a number of very different conditions." May I suggest that if these conditions are regarded ab initio as "very different," and if it be assumed that the common factor is to be "discovered" rather than demonstrated, there is some danger of a block on the line of progress.

The conditions actually mentioned are small-pox, vaccinia, measles, and after antirabic treatment. All these are occasionally associated with encephalomyelitis. We may add to the list chicken-pox and rabies as well as those idiopathic examples which may or may not be associated in human beings with influenza and in animals with distemper. But however we construct our preliminary group it becomes clear that there is a type of reaction to infection of which encephalomyelitis is one of the characteristics. We are not unacquainted with types of reaction in a broad sense. Thus the lesion which occurs after the lodgment of germs of the tuberculosis-streptothrix order is of a very different character to that associated with the genus streptococcus. Each is different again to that caused by the many varieties allied to *B. typhosus*, and typhosus infections are not easily confused with mycotic diseases. Bearing such broad groups in mind, it is interesting to observe that many of the encephalitic group have been shown to be associated with diseases caused by a virus and that none of the group has been shown to be caused by any other sort of organism.

It is possible that virus infection is the desired "*common factor*" *underlying these* "*very different* conditions." If that were so, we might hope to be able to identify some general type of reaction analogous to the general type favoured by other groups of infective agents. Of this general type encephalitis of occasional occurrence would be one feature. Another might be the tendency to epidermal vesicular lesions. A third might be the type of response identified in the tissues by the microscope—i.e., the response by lymphocytic proliferation rather than the evidence of tissue destruction which is also seen.

It is not for the writer of this letter—a general practitioner—to define the group with exactitude. But it sometimes happens that those who have had no opportunity to make a close study of the trees happen upon a vague but useful idea of the general size and shape of the wood. It is quite likely that viruses differ among themselves and that only certain of them react as members of the encephalitic group. But if we concentrate on those different conditions mentioned and seek to elucidate all the points which they have in common, we may well find a group in which occasional encephalitis will be no more surprising than is an occasional bone abscess in typhoid. We might then cease searching for the germ of encephalitis and concentrate on those factors which make every virus in the group potentially encephalitic. And although micropathology will doubtless have its share in the quest, it will perhaps not enjoy the position of almost exclusive pre-eminence which it has attained to-day. It has reached this position by the skill of its devotees, and the fault (if there be any) is that of the general pathologists, the students of morbid physiology, who have been too content to view this subject through the microscope.

At least, so the writer feels and signs his name, with some trepidation,

Yours faithfully,

Sevenoaks, Kent, Dec. 15th, 1929. GORDON WARD.

CLINICS FOR RHEUMATIC CHILDREN.

To the Editor of THE LANCET.

SIR,—Dr. Burnet's letter raises points of first importance. Its main object is to urge the development of special clinics for rheumatic children and there appear to be several reasons why we should hesitate to recommend the formation of such clinics all over the country.

In the first place, rheumatism of childhood in its different aspects and degrees of severity is so widely spread and the numbers involved are so great that it would probably mean the attendance of about 20 per cent. of the elementary school-children. If the chief object of such clinics would be to prevent rheumatism in its more severe forms then unless the potentially rheumatic or so-called "pre-rheumatic" child is to be included in the attendance at these clinics, the clinics from the point of view of prevention would be useless and a waste of money. Apart from the use of salicylates in some of the active cases and provision of rest for the heart cases there is hardly anything that can be offered in the way of treatment. The rheumatic problem is a social one and is entirely one of prevention, and it appears to me that we can no more prevent rheumatism by rheumatic clinics than we can prevent a wet day by putting up an umbrella.

I would, however, be in agreement with Dr. Burnet in the development of investigation centres which would have as their main object the intimate study of the disease in all its aspects, and with him I would urge the provision of more beds for the heart cases in all the large centres.

Again it would be a mistake to divert active rheumatic cases from the private doctor who is so closely in touch with the home conditions or from the hospital clinics who have for so many years been engaged in the important work of investigation and the teaching of the medical student. A great part of our knowledge of child rheumatism has been won by the hospital physician, and the names of Cheadle, Barlow, Lees, Poynton, Carey Coombs, and Reginald Miller should be remembered in connexion with this. Hospital teaching and investigation have already suffered much by the loss of tubercular cases, and it would be unwise to allow this to happen in the case of the rheumatic affection.

It appears to me that as regards the prevention of this appalling disease the public health services, and more especially the welfare centres and school medical services, have a great opportunity. Dr. Burnet is, I think, rather too severe in his criticism of the medical officers staffing these services. Agreed that many of the doctors are at present accepted for service without adequate children's experience and that their time is largely taken up by that soul-destroying business of amassing statistics for annual reports, yet there is undoubtedly in being a body of men and women eager, I feel sure, to tackle this urgent problem if only their administrative heads will organise a campaign. What can be done? In the first place, prevention of rheumatism must start with the "well" child of one year and must continue up to the last day of the school period. The welfare centres and the school services must therefore at once be linked up under one administrative head, and I suggest that through their combined agency a really comprehensive campaign should be instituted with regard to the efficient feeding of the child. The medical officer must be prepared to pick out all those children who are potentially rheumatic and not merely those who are frankly rheumatic, and these children should either be fed at school or steps taken to insure that they are efficiently fed at home. Those children with frank, active rheumatism should be brought in immediate touch with the private doctor or hospital clinic, and here again a far closer coöperation must be instituted between the different medical agencies than at present exists. The development of the nursery school and the open-air school must also form an important part of the measures to be undertaken with regard to the disease.

There are those who still believe that the beginning and end of the rheumatic problem lies in the early removal of tonsils and adenoids. I fancy, however, that the number of such is getting less, although none of us will deny that the healthy nasopharynx is an important factor in the health and resistance of the child, and it would appear that the present school medical service is in a specially favourable position to attend to this important, but not the most important, factor in the prevention of the rheumatism of childhood. I hope, therefore, that the profession will whole-heartedly support and encourage the further development and work of the welfare centres and school medical service, for in their hands lies the future progress in the prevention of rheumatism with its resultant heart disease.

I am, Sir, yours faithfully,

C. WILFRED VINING, M.D., F.R.C.P.

LIVER TREATMENT IN ESSENTIAL THROMBOPENIA.

To the Editor of THE LANCET.

SIR,—In a paper on the Clinical Significance of the Blood-platelets which Dr. R. G. Bannerman and I contributed to your series of Clinical Interpretation of Aids to Diagnosis (THE LANCET, 1929, i., 1048) we gave reasons for thinking that the liver treatment of pernicious anæmia is likely to be of therapeutic value in other conditions in which there is a primary thrombopenia. A case of essential thrombopenia which has been so treated, and apparently with success, has been published by Dr. S. A. Holbøll in *Hospitalstidende* for August 8th (p. 841). As the Danish journal is unlikely to be accessible to many of your readers I venture to draw their attention through your columns to this paper which seems to justify the application of liver treatment to cases of essential thrombopenia before the alternative and more heroic treatment by splenectomy is adopted.

I am, Sir, yours faithfully,

W. CRAMER.

MALIGNANT GROWTH AND PELLAGRA.

To the Editor of THE LANCET.

SIR,—Dr. Trevor Heaton describes in your issue of Oct. 12th (p. 762) how the growth of malignant tumours in rats may be arrested by the injection in large doses of certain extracts from malt. He suggests that this effect is due to a "growth inhibiting factor" which is present in the extracts. He states that "after the growth of their tumours had been arrested the animals usually died." This appears to me to be a very important point in that it shows that the vitalities of the tumours and the tissues of the rats were more or less equally affected by the treatment. It is well known that the degree of growth of malignant tumours often varies with the general health and vitality of their hosts. They grow more rapidly in young and vigorous patients than in the old and decrepit; and occasionally carcinomas cease to grow and may even disappear in the case of very senile patients.

Many years ago when I was resident surgeon to the hospital in St. Lucia, British West Indies, a mulatto woman consulted me for a tumour of the breast, I diagnosed it as a scirrhus carcinoma and urged her to be admitted to hospital for operation; she refused. Several months later she was brought to hospital suffering with pellagra, and then I was unable to find any signs of the tumour in the breast. The woman died and a post-mortem examination was made and an examination of the breast and axillary glands showed only fibrous changes and no signs of the tumour. The pathology of pellagra may be summed up as a cellular degeneration affecting all the tissues of the body; so that there is general emaciation and profound wasting of the epithelial tissues and the visceral organs. Therefore it would not be astonishing if the general cellular degeneration also affected carcinomatous tissue. Carcinoma of the buccal mucosa (betel chewer's cancer) is common in Ceylon; and several years ago I treated a few patients having inoperable growths with large doses of extracts of carcinomatous tissues which had been removed at operation from other patients. These extracts produced much debility and increased the wasting in the patient; and in all cases the carcinomatous masses diminished in size. Only two patients could be induced to continue the treatment and in both cases the tumours disappeared leaving large excavations in the cheeks. These patients were shown before the Ceylon branch of the British Medical Association. They were in a very low state of health, but it was hoped that they would recover after the cessation of treatment. But both of them died of progressive wasting and debility in a few weeks. A post-mortem examination was obtained on one of them, and no remnants of carcinomatous tissue could be found either macroscopically or microscopically.

The point which I wish to bring out is that malignant growths (especially those of epithelial origin) are almost unique in pathological processes in that they are more or less profoundly affected by certain types of generalised cellular degeneration taking place in their hosts. This degeneration may be the result of the injection of foreign substances, or the result of such a disease as pellagra or due to senility. This is not only of ætiological significance, but may be of importance in the treatment of patients. The result of Dr. Heaton's treatment of rats harbouring Jensen's sarcoma was the same as in the case of the two patients treated by me—the tumours disappeared but death followed. Extracts of tissues or malt in small doses might enhance the effects of radium treatment. Perhaps a more promising method would be the production dietetically of a mild generalised degeneration.

Though the cause of pellagra is not definitely settled it is very probable that it is a food deficiency disease. Goldberger and Wheeler in America claim to have produced the disease in prisoners by giving a diet rich in carbohydrates and deficient in proteins. But more recent work indicates that the absence of a vitamin may play a part. This vitamin is abundant in yeast and was designated P–P by Goldberger, B_2 by British biochemists, and G by American biochemists. When this vitamin is withheld from the diet of rats, their growth is arrested, and their skins become susceptible to various rays and exposure to these will produce epidermal degeneration with the destruction of the superficial layers of the epidermis. A similar condition takes place in patients suffering with pellagra, and they are exceedingly susceptible to the sun's rays. The proteins of various foods have not the same value in growth promotion; this has been called the biological protein value. This value depends on the relative amounts of the amino-acids, tryptophane, and lysine present in the protein molecule. It is probable that a double deficiency of vitamin B_2 and of proteins of high biological values are concerned in the cause of pellagra.

It is too much to hope that the production of a mild pellagrous condition in patients afflicted with malignant tumours would be sufficient to cause the arrest and absorption of the tumours. Yet it appears that a diet deficient in growth-promoting factors and which renders the cells susceptible to injury by rays is indicated for patients being treated with X rays or radium.

I am, Sir, yours faithfully,

LUCIUS NICHOLLS, M.D. Cantab.,
Director, Bacteriological Institute, Ceylon.

Colombo, Nov. 16th, 1929.

OLD EPSOMIAN CLUB.

ANNUAL MEETING AND DINNER.

THERE are at the present time 877 enrolled old scholars of Epsom College, of whom 118 attended the annual meeting and dinner of the Club at the Wharncliffe Rooms on Dec. 12th. This was the fifty-second gathering of the Club and the attendance was the same as last year and larger than on any other occasion. Leavers of nearly every possible year were represented under the genial chairmanship of Brig.-General T. G. Mair (1865–69), late Colonel Commandant of Sierra Leone. We add the dates of his school years to emphasise the fact that the common bond was that of having lived and played rather than worked together. The Chairman, in proposing "Floreat Epsomia," said that 300 of the present boys are members of the Officers Training Corps, the remaining 100 being ineligible owing to youth or health—a 100 per cent. record. He spoke of the death of the President, Lord Rosebery, to whom the school owed its very name, and of the appointment of Lord Burnham to succeed him. He welcomed the presence of Sir Henry Dixon Kimber (1873–81) who is standing next year as a Sheriff of the City of London, and he paid tribute to the Headmaster as "a live wire in everything he does." Mr. A. C. Powell, replying, gave some of the school's current academic records—46 matriculations, six with honours, 12 first M.B. passes during the last 12 months, entrance scholarships at three London hospitals—but was followed with greater acclamation when he set out the record of the cricket XI. with eight wins, three draws, five losses, and of the Rugby XV. with nine wins, one draw, and no loss. The toast of The Guests was proposed by Mr. A. C. C. Parkinson (1890–1903) who dealt searchingly with the gaps he had observed in medical knowledge which, he said, resembled wire fencing in being "a concatenation of lacunæ." Response for the guests was made by Dr. A. Middleton Hewat, senior medical officer, L.C.C., not an old scholar but with two sons at the school. The toast of The President was proposed by Mr. J. S. Cotman (1887–93). In the course of the evening Sir Cecil Armitage (1884–85), late Governor of Gambia, presented the golf championship cup to Mr. H. L. G. Hughes (1903–10). The meeting took for granted the services of the hon. secretaries of the Club, to whose labours its success was so largely due—namely, Mr. R. M. Handfield-Jones (1907–10) and Major W. L. Giffard.

Obituary.

DANIEL LEWIS THOMAS, M.R.C.S. ENG., D.P.H.

WE regret to announce that Dr. D. L. Thomas, medical officer of health for Stepney, died on Dec. 10th at the age of 60. His record in the public health service commanded general respect, while his personal characteristics won many friends and brought him a warm welcome in many different quarters.

Daniel Thomas was born in Newcastle Emlyn, South Wales, and served a year's apprenticeship there with the late Dr. Lloyd before entering on his medical course in London. He always felt very thankful for this year; he used to say that it was one of the best preparations a man could have, and he remained one of Dr. Lloyd's closest friends. In 1886, he entered the London Hospital and thus formed an association with the East End which continued uninterruptedly to his death. Immediately after qualifying in 1892 he started as a general practitioner in the Mile End-road and he soon had a lucrative practice, but in spite of increasing responsibilities, he found time to read for his D.P.H., and in 1896 when there was a vacancy for the post of medical officer to the Limehouse District Board of Works Thomas was elected. On securing this appointment he studied law and was called to the Bar in 1900.

DR. D. L. THOMAS.

[Photograph by Elliott and Fry.

He remained medical officer to the Limehouse Board of Works until the district ceased to exist as a separate sanitary area. Under the Local Government Act of 1899, Limehouse was united with Whitechapel, Mile End, and St. George's in the East, and formed into the present Borough of Stepney. In the autumn of 1900 Dr. Thomas was elected the first medical officer of health of this borough, where he had worked since his entering the London Hospital as a student. Although the conditions of general practice at that time had something to do with his decision to enter the public health service, undoubtedly the course of events proved his decision to be the right one. He entered into his work with all the ardour of youth and the enthusiasm of the pioneer; and both were needed, for the difficulties with which he had to contend appeared almost insuperable. He was the first whole-time medical officer of health for Limehouse, and also for Whitechapel, Mile End, and St. George's in the East. His predecessors were all doctors in general practice. The soil was practically virgin soil. The infantile mortality was in the neighbourhood of 200 per 1000 births. The credit of being the first district to appoint a health visitor is claimed by many towns and probably the honour is due to St. Helens, but Stepney was one of the first London boroughs to make such an appointment, and from this beginning was built up an elaborate system of child welfare centres, day nurseries, and antenatal clinics. A feature of the work at Stepney was the numerous voluntary agencies which worked for the public health, and to Dr. Thomas is the credit for smoothly coördinating these agencies and fitting them into one scheme for maternity and child welfare.

In his early days as medical officer Thomas had to fight grimly against the sophistication of food and the sale of diseased meat. It is probable that he was more than any other health officer instrumental in the prevention of the sale of diseased meat. He was, of course, backed by his council and ably supported by the late Mr. Dickenson, who was then the magistrate at the Thames Police-court. Some of the offenders suffered imprisonment and the new medical officer was threatened with all kinds of penalties if he proceeded against the law-breakers. But neither threat nor cajolery could effect any deviation from what he considered to be the strict path of his duty. His district bordered on the river and contained some of the largest wharves in London. Food inspection early claimed his attention, and in those years he was constantly called upon to give expert evidence upon the condition of tinned food. Stepney suffered severely in the small-pox epidemic of 1901 and 1902, and recently in the present epidemic of mild small-pox. He had seen thousands of cases of small-pox, and as his clinical acumen was of a very high order, he was recognised as an authority in the diagnosis of the disease. He published privately a brochure on diagnosis in the present outbreak, and the medical practitioners of Stepney to whom it was issued found its contents extremely valuable and suggestive.

During the war Dr. Thomas undertook night duty at the London Hospital in order to relieve the overworked staff, and he was one of the few medical officers of health appointed as local food officers. He acted as executive food officer for his borough during the period of food control and also during the general strike. With its cosmopolitan population Stepney was one of the most difficult districts to administer, and abuses were prevented only by his wide and deep knowledge of its citizens.

It has been said of Thomas that he was "a Celt to his finger-tips, with all the national characteristics and prejudices of the Celt. He was in some respects a paradox. In the office he was a strict administrator, utilitarian in his views; outside he was a dreamer and an idealist. In public he was efficient and economical; in private generous. He was a mystic, but he was also intensely sociable." Possibly it was on account of the blend of mysticism and sociableness that Freemasonry appealed to him. He admired its ritual and welcomed its opportunities to exercise the virtue of charity. He was a Past Grand Director of Ceremonies, a founder of several lodges, and a liberal supporter of all the Masonic charities. For many years he was chairman of the London Welsh Rugby Football Club, and he was connected with so many other organisations that no social function amongst the London Welsh seemed complete without the presence of "Dr. Dan" as he was affectionately called. The association with Wales was retained to the end, for he spent his summer vacation every year on the Cardiganshire coast, and was known by fame to large numbers of his fellow-countrymen, even in remote parts.

Dr. Thomas died of psittacosis in the London Hospital, with which he had been connected directly or indirectly since his student days. He leaves a widow with a son 8 years of age.

JOHN SADLER CURGENVEN, M.R.C.S., L.S.A.

Dr. Curgenven, whose death occurred in an attack of angina pectoris on Nov. 25th at his home at Chiddingfold (Surrey), was educated at Merchant Taylors' School, and entered St. Bartholomew's Hospital as a student in 1881. Four years later he took the qualifications of M.R.C.S., L.R.C.P., L.S.A., and joined his father, Dr. John Brendon Curgenven in a well-established practice at 12, Craven Hill Gardens, Bayswater. Both father and son were much in request for the treatment of childish ailments, and the son wrote for the use of his own patients a little book, "The Child's Diet," which has had a wide circulation in three editions since its first appearance in 1905. *On the retirement of his father in 1890* he carried on the practice singlehanded until 1916, when he joined the R.A.M.C.; in the last year of his service with the Corps he was P.M.O. for the district round Bath. On demobilisation he retired to the country and lived at "Granthams," Chiddingfold to the time of his death.

Dr. C. W. Emlyn writes: "Curgenven was a very eminent practitioner, and a man of fine character and great personal charm. He never enjoyed robust health and the weight of his large practice often tried his strength, though he worked on cheerfully and thoroughly. He looked forward keenly to the leisure of retirement, and to having a garden of which he was very fond. Like most Cornishmen he was irresistibly drawn to the rugged scenery of his ancestors, and from his cottage at Coverack he devoted *himself to sea-fishing with the rod.* He *knew a lot* about church architecture, and an excursion with a friend who shared the same enthusiasm was one of his chief delights."

Dr. Curgenven married Ethel, second daughter of Mr. Maurice Grant of Lancaster Gate, Bayswater, who with their only daughter survives him. He was buried at Brookwood on Nov. 29th, within two days of his sixty-seventh birthday.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE MENTAL TREATMENT BILL

IN COMMITTEE IN THE HOUSE OF LORDS.

ON Tuesday, Dec. 10th, the House went into Committee on the Mental Treatment Bill, the Earl of DONOUGHMORE, Chairman of Committees, in the chair.

Power to Receive Voluntary Boarders.

Clause 1 provides that any person suffering from mental *disorder who is desirous of voluntarily submitting himself* to treatment, and who makes written application, may be received as a voluntary boarder in an institution without a reception order.

Lord SANDHURST moved an amendment to omit the words "suffering from mental disorder" in order to make it as easy as possible for persons suffering from incipient symptoms to become voluntary boarders. It should not be necessary for a person to be so far gone in the disorder as the words in the clause implied before submitting himself to treatment. Under the corresponding section of the Lunacy Act, 1890, there was no definition of a voluntary boarder. All that was necessary was that a person should be desirous of voluntarily submitting himself to treatment.

Earl RUSSELL accepted the amendment in a slightly altered form, and it was agreed to, the clause then reading "any person who is desirous of voluntarily submitting himself to treatment for mental disorder," &c.

Viscount BRENTFORD moved an amendment to alter from 18 to 21 the age at which any unmarried person suffering from mental disorder, whose parent or guardian is desirous of submitting him to treatment, may, if the parent or guardian makes written application, be received as a voluntary boarder. He said it was a little questionable whether a person of 18 should be allowed under any circumstances voluntarily to place himself or herself in a mental home.

Earl RUSSELL explained that the age of 18 was adopted from an amendment which the House inserted in the Mental Treatment Bill of 1923. It was thought well to follow that Bill. He suggested that Lord Brentford should agree to a later amendment in the name of Lord Danesfort to accompany the consent by a medical certificate.

The amendment was accordingly withdrawn.

Consent of Parents in Adolescent Cases.

The Earl of CRANBROOK moved an amendment to provide that where an unmarried person was not under 16 his consent to the application by the parent or guardian should be given in writing. He said that he was moving the amendment on behalf of the London County Council, which had a great many mental institutions of considerable experience in dealing with people suffering from mental disorder. The Council felt that the age of 18 was too high for the parent to have sole control.

Earl RUSSELL said that it would be better not to accept the amendment in view of the one to which he had alluded, which would reinforce the judgment of the parent or guardian by a recommendation of a medical man. In that case their lordships would feel that a person whose parents expressed a desire that he should be treated voluntarily would be protected if the application were supported by a medical man. The Government proposed to use the word "recommendation" rather than "certificate." They wished to avoid the use of the word "certificate," which suggested the certification of a patient.

The Earl of CRANBROOK pointed out that persons of 16 who were able to marry—a much graver step than going for treatment to a mental hospital—should have a voice in their own affairs.

Lord DAWSON said that if they were dealing with people of normal mind he would give his support entirely to a young person having the right of decision, but unfortunately Nature had decided this matter, and these mental disorders, which might easily develop into insanity properly so-called, very often arose at the ages of 16 and 18. The very existence of these mental disorders, slight as they might be at that stage, made these young people very difficult. Sometimes it was almost impossible to cure them in their own homes. They were, in a sense, anti-social, and therefore they needed rather more pressure than persons who were normal. In fact, these young people *suffering from these incipient disorders* were to be looked upon more in the light of normal persons who were younger by two years, and it was because of the conditions which they had to meet that it was desirable to put a little more power in the hands of the parents in respect of this particular type of ailment. If they provided that there should be a medical certificate or medical recommendation—which, he agreed, was the better term—they would meet the difficulty and safeguard the Bill against abuse.

Viscount BRENTFORD said that the whole tenor of Lord Dawson's speech made him anxious. The clause related to the voluntary right of a person to shut himself up. It was not a question of pressure, but of a condition of mental disorder under which the patient was not able to take a voluntary decision. Under the clause a young man of 18 might, if he wanted, make a voluntary decision and go into a mental home without any doctor's certificate.

Lord DAWSON: With a doctor's certificate.

Lord BRENTFORD: Without. The voluntary judgment of this so-called voluntary patient was to be taken away, and pressure was to be put on him by the parent and the doctor who was prepared to sign the recommendation. The very essence of the clause was that it was voluntary and the amendment would be an improvement. It would make the Bill more popular as well as more reasonable.

Lord BANBURY said that he agreed with Lord Dawson that the clause was not a voluntary one, but one which might lead to pressure.

The amendment was withdrawn.

Lord DANESFORT moved an amendment to provide that a young person under 18 might be received as a voluntary boarder if the written application of the parent or guardian were accompanied by a medical recommendation. He said he understood that the Government were prepared to accept the amendment. It was quite possible that in some cases there might be parents or guardians who would like to lock up a child who might be a little unruly or disagreeable, and in the interests of the liberty of the subject it was desirable to have some further protection in the Bill. On the second reading, Lord Dawson and others had suggested that this incarceration of a young person should not take place unless there was a medical certificate or recommendation stating that it was desirable for him to be so detained. He moved the amendment as being, at any rate, a partial remedy for what might have been a great evil.

Earl RUSSELL said that if it was desired to afford an expression of will in regard to persons between 16 and 18 he would consider the matter before the Report stage.

Viscount BRENTFORD expressed regret that a young person under 18 could be locked up in any home or asylum without judicial proceedings. Under the clause as it was proposed to be amended, a young person who might be a troublesome or even unwanted child was to be locked up on the recommendation of one doctor without the right, which he had to-day, to go before some kind of judicial officer, even a magistrate.

Lord ATKIN urged that some provision should be made to meet the case of a young person whose consent had been obtained to being placed in a hospital to begin with, and who could only be removed at the request of his parents or guardian.

Lord MERRIVALE said it would be a grave innovation on the Common Law rights of His Majesty's subjects if, instead of the age of 16 which for generations had been known as the age of right and responsibility on the part of individuals, they substituted an arbitrary age without any safeguard except the certificate of one medical man.

Earl RUSSELL agreed that this was an invasion of the Common Law right of personal liberty, which was recommended in the interests of the patient. It would be for the House to decide whether or not, on balance, the course proposed would be in the interests of those patients and would lead to their recovery. The question of the consent of the person of 16 had not been met because the suggestion that he should consent before going in had not been before them until that moment. It followed naturally that if the patient over 16 had to consent to go in for this treatment he must continue to consent when he was there. That would be one of the matters which he would consider on the Report stage.

The amendment was agreed to.

Boarders who become Incapable of Volition.

Clause 2 provides for notice of reception, death, or departure of voluntary boarders and makes provisions for boarders who become incapable of volition. The third paragraph of the clause provides that if any person received as a voluntary boarder becomes at any time incapable of volition he shall not be retained as a voluntary boarder for longer than one month, but shall on or before the expiration of that period be discharged, unless in the meantime he has again become capable of volition or steps have been taken to deal with him either under the principal Act as a person of unsound mind or under this Bill as a person incapable of volition who is likely to benefit by temporary treatment.

Lord SANDHURST moved an amendment to provide that the medical superintendent or other person in charge of the institution should decide whether the voluntary boarder had become incapable of volition. He said that somebody should be made responsible for formulating an opinion as to the patient's incapacity of volition. Nobody could more properly be made so responsible than the superintendent of the institution, or the person into whose charge the voluntary patient had gone.

Earl RUSSELL accepted the amendment, which was agreed to.

Temporary Treatment without Judicial Authority.
Lord Brentford's Amendment.

On Clause 5 (Provision for treatment without certification of persons temporarily incapable of volition),

Viscount BRENTFORD moved in Subsection (1) to leave out the words "on a written application duly made in accordance with the provisions of this section but without a reception order." He said that the question he desired to raise was whether these patients who were suffering from mental disorder, and who were incapable of volition but likely to benefit by temporary treatment, might be shut up under the decision or certificate of two doctors without the judicial authority which up to the present had been regarded as of vital importance. The Royal Commission did not take the view which the Government had adopted, and he (Lord Brentford) desired to move an amendment which embodied the proposal of the Commission. It had been drafted by a lawyer with that purpose in view. He suggested that the Royal Commission's view was the right one, and that the Government's view was wrong. In order to save the expense he proposed that instead of two doctors there should be only one, but that there should be a magistrate who should see the patient, and his friends if necessary, and decide whether it was really desirable in the interests of the subject that the liberty of the subject should be done away with. That was a very important matter. Up to the present they had never allowed that liberty to be interfered with by any advisers, except under judicial authority. If the form of judicial authority proposed was objected to he would assent to any form which met with the approval of Lord Russell. But was it not a very great alienist who said that the number of wives who came to ask him to certify their husbands was only equalled by the number of husbands who came to ask him to certify their wives? There was nobody who was directly the friend and adviser of the incipient patient except a judicial authority who was quite independent of those who desired to place the patient under control. The question had nothing to do with the skilled opinions of medical men as against those of the law; it was a question whether there should be any person unconnected with the patient, unconnected with the medical adviser, somebody representing the law of the land, called in to consider if the patient should be locked up or not.

Earl RUSSELL said they might take it that this amendment was a test amendment covering the whole of the suggestions which Lord Brentford had made on this part of the Bill.

Viscount BRENTFORD: Certainly.

Earl RUSSELL said that neither he nor the Minister of Health had any objection to a judicial authority in itself. The objection, unfortunately, came from the patient and his relatives. It was quite true that a judicial authority was recommended by the Royal Commission with great reluctance, but it was thought very much better for the patient that the matter should be done in a less formal way. They wanted under this Bill to treat incipient mental disorder without the stigma of certification. He would beg Lord Brentford not to talk about persons being "locked up," and being "put away." Those were the very expressions which it was desired to get out of the mind of these patients. They wanted to talk to them about being treated for their health, and to assimilate the treatment as far as possible with the treatment for ordinary illness. Detention might be a necessary part of it, but it was not the part on which they desired to insist. He would ask their lordships to reflect on the protection given by the Bill. Did they suppose that if two competent medical men had signed a certificate giving perfectly clear facts on which they based their conclusion that a justice would take upon himself in the ordinary way to override that certificate? The most he could do would be to see that everything was regularly done. That, of course, became the duty both of the superintendent of the institution to which the patient was taken and of the Board of Control who received the certificate. They were much more competent to perform that duty than the ordinary justice. He asked their lordships not for the sake of a fetish to throw away a reality, and to resist Lord Brentford's amendment.

Lord DARLING said that Mr. Hugh Macmillan, K.C., who was the Chairman of the Royal Commission, was of opinion that what was proposed in the Bill was the proper way of dealing with these incipient mental cases. He was not a doctor; he was a justice of the peace for every county in England, because he was a member of the Privy Council, yet he had come to the conclusion that the intervention of justices of the peace would be bad for the patient.

Lord LAMINGTON said he hoped Lord Brentford would withdraw his amendment.

Lord SANDHURST said that Lord Brentford had referred to the fact that for 200 years the law had been such that a patient's liberty could not be interfered with except with judicial authority; but 200 years ago views on lunacy were entirely different from those of to-day. He hoped that the amendment would not be carried.

The Earl of ONSLOW said that he quite saw the point made by Lord Russell and by other speakers that it was very difficult to distinguish in the public mind between a certificate for temporary treatment of a man who was not a lunatic and a full certificate. He (Lord Onslow) would suggest that it might be possible to entrust the endorsement of the recommendation of the two medical men to the Commissioner or the Assistant Commissioner of the Board of Control, or at any rate to the authority of that Board rather than to a judicial authority.

Lord MERRIVALE said he hoped that Lord Russell would consider Lord Onslow's suggestion. In 999 cases out of 1000 it was most desirable that these people should be under treatment, but everyone knew that the odd case occurred, whether through interest or malice, or some indirect motive, and produced mischief. Certainly it had been the practice in this country to safeguard the liberty of the subject. The present procedure was really not a safeguard. For a delicate matter of this kind he thought they might have a body of referees nominated in the public interest as proper persons. There would be a panel of qualified persons in whom medical men and everyone else who know anything about the matter would have confidence.

Lord HANWORTH said that he hoped that the Government would hold to the Bill. If the matter was pressed to a division he would vote against the amendment. The same reluctance would be shown to go before a board of referees as to go before the magistrates. The stigma was really the same and such a step would interfere with the recovery of these patients. So long as the matter was left in the hands of the medical man, and treatment was given by the medical man, there was some hope for them. After all, they were only going to be treated for six months with the safeguards provided in the Bill.

The Marquess of SALISBURY said that their lordships would appreciate that the matter was one of some difficulty.

The decision was not a purely medical one. Unless Lord Russell was willing to consider the difficulty of determining what the actual volition of the patient was, and whether he had exercised it, then he (Lord Salisbury) would feel a great difficulty in regard to his vote.

Earl RUSSELL said that he did not think that the difficulty would arise in practice. The person was not necessarily comatose—confusional was rather the word. A great many of the confusional cases were so excited and upset by the procedure of certification, and by seeing a justice, that it very often put them back as much as six weeks before they began to make progress in the quiet surroundings of the asylum. That kind of excitement was very bad for their unstable brain. The patients were very well protected, and he hoped that their lordships would reject the amendment.

Viscount CECIL of CHELWOOD suggested that a way out of the difficulty might be to insist that one of the two medical practitioners who were to sign the recommendation for temporary treatment should be a person who had been proposed for the purpose by the Board of Control.

Earl RUSSELL said that that was a valuable suggestion, and he would certainly consider it before the Report stage.

The Medical View.

Lord DAWSON said he would like to make it clear that the medical profession had no objection to safeguards, provided those safeguards were such as would not prejudice the cure of the patients. They frankly admitted that those patients with which this Bill dealt constituted a class that had not hitherto been dealt with by the legislature. They were people for the most part living in small houses and earning small incomes. The difficulties were much less among the well-to-do. They had large houses where persons mentally sick might perhaps have two nurses and where the treatment could be carried out quite easily. The class of patient to which this Bill referred was a class that was grievously suffering with very little or no opportunity of being relieved. Take the case of an out-patient at a hospital. That patient might have influenza or some simple illness. He went there with a feeling of depression under a power of self-criticism, subject to introspection, and might go step by step down to that absolute suffering which they all knew, and for which they were powerless to do anything under present conditions. If they wanted to do anything with such patients now they had to be certified. That brought him to the question of certification. The word conveyed notions of a madman and all the things that had been from generation to generation associated with that name. He was quite prepared to admit that many of the fears entertained were unreasonable, but they existed, and those who had to do with the sick constantly found these difficulties arising. It had to be borne in mind that the patient whom they hoped to help by this Bill was often a very sensitive, a very impressionable, and sometimes a very competent person—someone who was cut a little bit too fine for the environment in which he had been placed. These people were very easily wounded—he meant in their nervous system. They were a class which was increasing in the civilisation which existed to-day. They might be very competent in their work, they were very often efficient and capable of being leaders. They often came across them in the War. Such people might get some toxic condition arising from influenza; or, in the case of a woman, it might be due to childbirth. Under the stress or strain of that, or because of overwork, they began that down grade with which their lordships were familiar. They would have a want of confidence, would indulge in self-criticism and self-abasement, and might in the end become insane. There was no class which had to be more carefully handled by medical men. There was no class of illness which required a greater intuitive insight, a greater tenderness, and a greater sympathy. One false word and their influence had vanished. Very often they had carried the patients along and convinced them that all their distresses, their sleeplessness, that burden of life which had become a horror to them, was due to overwork and that by proper treatment they would get better. Then suddenly the patient turned and said: "Do you think I am mad? Do you think I am going to lose my reason?" They were so quick in feeling that. Supposing one had carried the patient along with one, or supposing he had reached the stage when the doctor had to put him under treatment, and at that time anything like certification was introduced the patient's friends and all the people in his social circle would entertain certain feelings towards him. It was a fact that certification was associated with a very grim past. Anything that interfered with the secrecy and the confidential relationship of medical advice was to be avoided, and that was why it was so important that the provisions of this Bill should be carried out. They could have precautions if they liked, provided they did not become so cumbersome as to render the measure nugatory. Their lordships knew how very anxious people were if there was any question of insanity in the family. It was for those reasons that he would like to emphasise the benefits of this Bill. It would enable the poorer classes to get at any rate some of the benefits which were now open to the more prosperous classes. Further than that, it would do what the medical profession, and those who had thought in this matter, desired: it would bring about the prevention of insanity. The Bill did not deal with insanity and therefore they asked that it should be kept away from all mention of the machinery of insanity. Its whole object was to take these people suffering from mental illness in the same way as they took people suffering from physical illness and treat each according to his need. If that was carried out, with any precautions that were suitable provided they did not run counter to the feelings of the people they desired to help, he was confident that this Bill would be of great service to the community.

Viscount BRENTFORD said that he realised the dangers and difficulties that might arise to the incipiently insane person, or the man or woman suffering from mental disorder, from the fact of the judicial inquiry which he had suggested, and that in consequence they might go over the line. But with all due deference to Lord Dawson, he (Lord Brentford) thought that the fact of finding themselves in a registered mental institution, or in a public lunatic asylum, was much more likely to have the effect of pushing these patients over the line than a more judicial investigation. He did not wish, however, to press his amendment either to carry it or lose it by a small majority. That would be undesirable in the interests of these patients and he proposed to withdraw the amendment and ask Lord Russell if he would consider the various proposals made by Lord Cecil and others which might get over this difficulty. They were worth consideration. He (Lord Brentford) would be very glad to discuss the matter with Lord Russell in order to arrive at a solution which he was sure the whole House desired.

Earl RUSSELL said that he would be only too delighted to confer with Lord Brentford on the matter.

The amendment was, by leave, withdrawn.

Extension of Temporary Treatment.

Lord SANDHURST moved an amendment to provide that where it was anticipated that a person who was undergoing treatment as a temporary patient under Clause 5 would not recover within the period of six months, but his early recovery appeared reasonably probable, that period might from time to time be extended for further periods of such length, not exceeding three months, as might be specified in directions given by the Board of Control upon the application of one of the persons making the original application, accompanied by such evidence or recommendations as the Board might by rules prescribe; provided that such further periods should in no case exceed six months in all. He said that the Mental Treatment Bill of 1923 contained a similar provision. It seemed to be obvious that if a patient having the advantage of temporary treatment without certification had not fully recovered, but was likely to recover, by the end of six months it would be a great pity to compel him to accept certification in order to complete recovery.

Earl RUSSELL accepted the amendment, which was agreed to.

Clause 5 was agreed to.

The Earl of ONSLOW moved on behalf of Viscount Brentford a new clause to provide that the rules made under the Bill should be subject to the sanction of Parliament.

Earl RUSSELL accepted the amendment, which was agreed to.

The Committee stage of the Bill was concluded.

BILLS ADVANCED AND WITHDRAWN.

THE Highlands and Islands (Medical Service) Additional Grant Bill was read a third time in the House of Commons on Dec. 9th, and was introduced in the House of Lords and passed through Committee without amendment on the 17th. On Dec. 12th the Children and Young Persons (Employment and Protection) Bill was withdrawn.

COLONIAL POLICY AND HEALTH SERVICES.

On Dec. 11th, in the House of Commons, Mr. MARLEY moved the following resolution:—

> "That, in the opinion of this House, the native population of our dependencies should not be exploited as a source of low-grade labour: no governmental pressure should be used to provide wage-labour for employers; due care should be taken of native social well-being; the native demand for land should be adequately and satisfactorily met and their rights therein properly safeguarded; where the native population is not yet fitted for self-government, direct imperial control of native policy should be fully maintained; native self-governing institutions should be fostered; and franchise and legal rights

should be based upon the principle of equality for all without regard to race or colour."

He said that it was not his intention, or that of the Labour Party, to make the coloured races and their problems the playthings of party politics in the House of Commons. It was generally recognised by the white races of the world that they owed a great deal to the coloured races, and that it was their duty to accept the trusteeship which economic power had given to them over the fortunes and destinies of those people. He would exclude India from the discussion, as that was the subject of a Commission whose Report in due course would receive a great deal of attention in the House and elsewhere. He appealed to the Government to see how far it was possible to institute a medical service or native hospital within the reserves. He was informed that there was only one native hospital in the whole of the East African territories, Uganda, Tanganyika, and Kenya. There was a medical service carried on by missionaries, very low indeed in regard to expenditure and very inefficient in regard to medical qualifications.

Mr. CHARLES BUXTON seconded the resolution.

Mutilating Operations on Women and Girls.

The Duchess of ATHOLL said she desired to bring before the House some reasons why some Members of the House who had been studying conditions among women and children in the Crown Colonies—women and girls particularly—felt that there was urgent need for more consideration to be given to the social well-being, health, and education of women and girls in some of the Dependencies than seemed to be the case at present. This small group of Members of all parties who had been considering this question for some months had met missionaries of different churches of long standing in different colonies, also laymen and women, including doctors, and they were all deeply concerned at many of the things which they had learned bearing on the the status, the health, and the welfare generally of women and girls. In particular they had been terribly impressed by what they had learned about the existence of a pre-marriage rite among young girls in African tribes, a rite which was frequently referred to as the circumcision of girls. This obtained in Southern Nigeria and among one tribe in Uganda, but it existed in its worst form among the Kikuyu tribe in Kenya. It was not a subject to deal with publicly, but she brought it before the House because none of them could afford to forget the responsibility for the Colonial Empire which was directly governed by that House. She doubted whether, apart from missionaries and doctors, and perhaps Government officials, there were many white people who realised what this rite was and what it meant to the health and well-being of the *girls and women.* The committee to which she had referred have been assured by medical men and missionaries who have attended these women in hospital and in their homes that the rite was nothing short of mutilation. It consisted in the actual removal of whole sets of parts connected with the organs of reproduction. The operation was performed publicly before one or two thousand people by the old woman of the tribe, who was armed with an iron knife. No anæsthetic was given and no antiseptics were used. The old woman went with her knife from one girl to the other performing the operation, turning the knife once or twice on each victim. A lady missionary steeled herself to see this operation not long ago and had given a description of it, fortified by photographs which she had taken. She told the Committee that the girl had a whistle put into her mouth so that her screams would not be heard. A medical man told them that the operation left great scarring and meant much contraction; the natural processes were gravely interfered with, and there was reason to believe that blood-poisoning resulted, with the consequence that there was terrible suffering at childbirth and the first child was rarely born alive. It was difficult to ascertain the extent of the mortality because there was no register of births or deaths, but one missionary who had attended many of these young women in hospitals on their confinement told her recently that out of 10 persons affecting 20 lives only six lives survived. She had also been told of a boarding house for 60 girls of this tribe where a death had occurred every year lately from sometimes a trivial cause. A cut finger might turn so septic, owing to the poisoning from which the girl had suffered, that that type of injury might cause her death. What was the policy of the Government in regard to this terrible thing? The Committee have also been assured by a medical man of standing in East Africa that while there was a lesser form of the operation, which was not so severe as form of mutilation as the one she had described, it was an operation which he would not sanction by anyone under his control. Surely one of the best ways in which to persuade people was to give them practical demonstrations of other and better ways; and that surely meant that every opportunity should be taken to help these people to be healthy, and to help the women to realise that if they did not go through the operation they could become mothers with much less suffering and danger to their children and to themselves. When they inquired as to what was being done in Kenya in the matter of the care of women in childbirth, they found that there were no midwives practising in the reserves; at least, that was their information. They were told that though there were several Government hospitals—Mr. Marley, who moved the resolution, she thought was misinformed on the question of hospitals—there were only women nurses in two of them. Therefore the majority of these hospitals were not very well equipped for attending women in their confinement. No doubt it might be difficult to find any women trained as midwives, but they could show a splendid example of what could be done in that way. They were informed that in the Protectorate there were 26 centres for maternity and child welfare, and as a result in the last ten years the infant mortality-rate had dropped from 500 per 1000 births—a terrible level—to not more than 130 per 1000 in Uganda. What was possible in Uganda should be possible in Kenya. Kenya had its mission boarding-houses and boarding-schools maintained by the various missions where African girls were admitted and given an all-round training for several years. She had no doubt that the training was the best possible training for practice as midwives. Referring again to the question of the pre-marriage rite, the Duchess of Atholl said that she had heard of a case of a Christian girl who wished to avoid being subjected to the more severe form of operation, but she was seized by her relatives and obliged to submit. Where the urgency of the question came in was this. An appeal was made to a native court for damages against the operator, but the magistrates ruled that no grievous hurt had been done to the girl.

Dr. MORGAN: What is the date of the prosecution?

The Duchess of ATHOLL said that she believed it was July of this year. The case was carried to the Supreme Court, where the decision of the native court was upheld, so that the woman who inflicted the terrible operation on this girl against her will only had to pay 30s. They must assume that the Supreme Court was carrying out the law, but in that case the law must be altered. She understood the policy of British Governments of all political complexions had been to avoid interference as far as possible with native customs, subject to this qualification, that they were not contradictory to justice and humanity. She asked the House what could be more inhuman that the practice which she had described.

Reply to the Debate.

After further discussion,

Dr. DRUMMOND SHIELS (Under Secretary of State for the Colonies), replying to the debate, said that the resolution referred to the social well-being of the natives. One of the first considerations in that connexion was health. In the Colonial Department increasing attention was being given to health questions. There were now 56 separate medical departments in the Colonies with 2000 qualified medical men and women. The Colonial Office served in some measure as an Imperial Ministry of Health. The Chief Medical Officer at the Colonial Office kept in touch with the medical problems of the overseas medical officers, and there was an advisory medical and sanitary committee and a medical research committee. These committees reviewed medical problems and stimulated and advised upon medical research. Very much more work and more research were required. They should be grateful to the Duchess of Atholl for raising the question of the pre-marriage rite. He could assure the noble lady that she was pushing an open door so far as he was concerned. He detested the practice, and he knew that the Secretary of State for the Colonies shared his view. It was his duty, however, to point out the difficulty of interfering with such traditional customs. While he did not say that that was an absolute bar to action, it did constitute a great difficulty. A number of the local Native Councils in East Africa had passed resolutions making illegal the severer forms of the operation. The Secretary of State was exploring the matter further, and collecting all the available information, and in the light of that, he might be able to take action which he hoped would satisfy the noble lady, and also satisfy the conscience of the House of Commons.

The debate was adjourned.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 11TH.

Colonial Health Services.

Duchess of ATHOLL asked the Under Secretary of State for the Colonies the numbers of the African populations of Tanganyika, Kenya, and Uganda, respectively; and, in the last year for which figures were available, what was the amount spent by the governments of these colonies, respectively, on midwives, hospitals, child welfare, and any other form of health service, and in the education of women and girls, distinguishing services supplied direct by government and services supplied by missionary bodies with the aid of a government grant.—Dr. SHIELS replied : The following is the information asked for. I may add that my noble friend is taking steps to ascertain what can be done to further the objects mentioned in the question and other matters of native welfare.

(1) The latest estimate of the numbers of the African population of these dependencies is as follows : Tanganyika, 4,740,706 Uganda, 3,241,543 ; Kenya, 2,838,022.

(2) In the last year for which returns are available the total Government expenditure in these dependencies on health services, exclusive of capital expenditure, was :—Tanganyika, £332,467 (1928–29) ; Uganda, £141,713 (1928) ; Kenya, £199,198 (1928).

(3) The following approximate amounts were spent on (*a*) upkeep of hospitals, and (*b*) construction and repair of hospitals (excluding in both cases expenditure on personnel).

(*a*) *Upkeep of hospitals.*—Tanganyika, £10,015 (1928–29) ; Uganda, £12,250 (1928) ; Kenya, £12,070 (1928).

(*b*) *Construction and repair of hospitals.*—Tanganyika, £14,974 (1928-29) ; Uganda £2,254 (1928) ; Kenya, £16,269 (1928).

(4) The other detailed information asked for as regards expenditure on Health Services is not available.

(5) As regards education, no figures showing separately expenditure on female education in these dependencies are available.

(6) The grants made by the three Governments to mission bodies in respect of health and educational services totalled :—(*a*) Tanganyika, £15,906 (1928-29) ; (*b*) Uganda, £30,641 (1928) ; (*c*) Kenya, £23,500 (1928). No information is available showing in detail the services on which these grants were expended.

Pensioners and Treatment Allowances.

Major COLVILLE asked the Minister of Pensions if he would consider amending the regulation in regard to treatment allowances which required that any payments from welfare or similar funds received by the pensioner during treatment should be deducted from the treatment allowance.—Mr. F. O. ROBERTS replied : The special allowances which may be payable during treatment are subject to the condition that the patient is found to be unable, in consequence of the course of treatment given to him, to provide for the support of himself and his family. It is, therefore, and always has been, a condition of the grant of those allowances that the patient shall not at the same time draw both the maximum allowance and also draw payment such as wages or sick pay in lieu of wages.

Married Men in Criminal Lunatic Asylums.

Mr. SORENSEN asked the Home Secretary whether he could give the figures of married men in the criminal lunatic asylums who were serving terms under commuted death sentence.—Mr. CLYNES replied : Two men now in Broadmoor Criminal Lunatic Asylum, having been transferred there while serving commuted death sentences, have wives living.

Health Insurance Benefits in the Services.

Sir KINGSLEY WOOD asked the Minister of Health whether he could state the additional benefits payable to members of the Navy, Army and Air Force Insurance Fund.—Mr. GREENWOOD replied : The additional benefits payable to members of the Navy, Army and Air Force Insurance Fund who continue their membership after discharge from His Majesty's forces are an increase of the normal rates of cash benefits by 4*s.* a week sickness benefit, 2*s.* a week disablement benefit, and 8*s.* maternity benefit ; payment of the whole cost of certain treatment benefits—viz., dental treatment and the provision of artificial teeth ; ophthalmic treatment and the provision of spectacles ; and the provision of medical and surgical appliances.

Position of Local Government Medical Officers.

Dr. VERNON DAVIES asked the Minister of Health if he had considered, in relation to the recommendation of the Royal Commission on Local Government (Final Report, page 107, paragraph 341), the case of medical officers of local authorities, such as a public vaccinator, a district medical officer under the guardians, and a medical officer of health to an urban or rural district council ; and whether he would issue a statement to local authorities as to the position of such officers in respect of membership of local authorities.—Mr. GREENWOOD replied : The recommendations of the Royal Commission are now under my consideration. I do not think that a special statement to local authorities on the matter is required at the present time.

Hospital Accommodation and Expenditure.

Mr. THOMAS GRIFFITHS asked the Minister of Health if he would furnish a return of the numbers and beds, comparable with that given in the House of Commons on 1st March, 1926, for hospitals provided by local authorities, voluntary hospitals aided by local authorities, institutions provided by Poor-law authorities, and giving, for the latest possible year, the expenditure in each of the three classes.—Mr. GREENWOOD replied : The following is the information asked for : So far as general hospitals are concerned, the information in my Department indicates that one large general hospital with 875 beds, and three relatively small accident hospitals have been provided by local authorities, but the total number of beds is not known. Local authorities are empowered by Section 84 of the Public Health Act, 1925, to make reasonable subscriptions or donations to voluntary hospitals to the extent of the produce of a penny rate. The amount subscribed by local authorities under that section in 1927-28 was £25,000. Under Section 38 of the Poor-law Act, 1927, Boards of Guardians may, with my consent, make contributions to public hospitals. In 1927-28 the amount contributed under this section was £44,000.

The information with regard to hospitals of the other classes referred to in the question is as follows :—

(A) Hospitals Provided by Local Authorities.

—	No.	Beds.	Expenditure of local authorities in 1927–28.
			£
1. For tuberculosis ..	160	12,787	1,802,000*
2. For acute infectious diseases	287*	36,833†	3,490,000†
3. Maternity hospitals (not including maternity wards in general hospitals or Poor-law Institutions) ..	79	1,034	201,447
4. Babies' hospitals.. ..	11	253	

* Including the expenditure in connexion with beds for tuberculosis mentioned in the following note.

† At 44 of these hospitals there are 2,205 beds for the treatment of tuberculosis. The expenditure on these beds is excluded from item 2.

(B) Voluntary Hospitals Aided by Local Authorities.

1. Tuberculosis hospitals ..	138	9,203	825,000†
2. General hospitals—			
(*a*) Used in connexion with tuberculosis schemes	164	—*	
(*b*) Used in connexion with venereal diseases schemes	130	—*	Not available.
(*c*) Maternity sections used in connexion with maternity and child welfare schemes	32	267	78,000
3. Maternity hospitals (not including maternity sections in general hospitals)	65	1,323	
Babies' hospitals	12	347	

* Available beds used as and when required.

† Including expenditure of the Welsh National Memorial Association on sanatoria and hospitals.

The figures under the above headings are exclusive of accommodation in homes for unmarried mothers and their babies, observation wards in connexion with maternity and child welfare centres, and convalescent homes. Those under *B* 2(*c*) are exclusive of accommodation used by local authorities in general hospitals for special or complicated maternity cases, as regards which figures are not available.

(C) Institutions Provided by Poor-law Authorities.

			£
1. Institutions wholly for the sick, exclusive of institutions for mental cases ..	73	40,000	4,119,000
2. General institutions (with a total accommodation of some 188,000)	542	83,000(*a*)	8,625,000(*b*)

(*a*) Beds in infirm and sick wards.

(*b*) Total expenditure on general institutions.

Vaccination Exemptions.

Mr. FREEMAN asked the Minister of Health whether he could announce any concessions in respect of the Vaccination Acts, which he promised to consider after receiving a deputation in October ; and whether he would arrange for a public inquiry, in view of the fact that more than 60 per cent. of the population claimed exemption for their children at birth.—Mr. GREENWOOD replied : I have under consideration the whole subject of vaccination, including the desirability of some further inquiry, but I am not at present in a position to make any announcement on this question. I may point out that the latest figures available—namely, those for 1927, show that in that year, not 60 per cent., but just over 40 per cent. of the parents made declarations of conscientious objection to vaccination.

The Standard of Overcrowding in the Census

Mr. SIMON asked the Minister of Health, whether he was aware of the standard of overcrowding adopted by the Registrar-General in the Census and by the majority of medical officers of health; and whether he would arrange for a more satisfactory standard to be adopted at the next Census, taking into account, in particular, the provision of the necessary bedroom accommodation to provide for the separation of the sexes.—Mr. GREENWOOD replied: This matter is receiving my attention in connexion with the preparations for the forthcoming Census.

Institutions for Mental Defectives.

Mr. EDE asked the Minister of Health how many local authorities had provided institutions for the residential care of the mentally defective; and how many had not up to the present made that provision.—Mr. GREENWOOD replied: Twenty-eight local authorities have provided institutions for the residential care of mental defectives. Eighteen have schemes in progress. Seventy-eight have not up to the present made any institutional provision of their own.

MONDAY, DEC. 16TH.

Appeal Tribunal in Pensions Cases.

Mr. GOULD asked the Minister of Pensions whether any steps had been taken with a view to securing a medical appeal tribunal to enable ex-Service men to submit their cases where conflicting opinions existed between the man's own doctor and the Ministry's medical advisers.—Mr. ROBERTS replied: The machinery of formal appeal to an Appeal Tribunal is, in my judgment, not the most suitable or most expeditious mode of determining such purely medical matters as the form of treatment appropriate to a particular case, where there is a difference of opinion on this point on medical grounds. I have, however, arranged that any difficult cases of this character, where representations are made by panel doctors, are reviewed at the Headquarters of the Ministry.

Deterioration following Final Award.

Mr. LONGDEN asked the Minister of Pensions if he would instruct area officers to grant the right of re-appeal for a renewal of pension, under the procedure for the correction of errors, where the ex-Service man claimed to be suffering from deterioration following a final award.—Mr. ROBERTS replied: I would point out that it is open to any pensioner in receipt of a final award to apply for treatment for a condition due to war service. If, as a result of such treatment, the award is found to have been seriously erroneous as an assessment for permanent purposes, a further grant can be made.

Married Inmates of Lunatic Asylums.

Mr. SORENSEN asked the Home Secretary the number of married inmates of lunatic asylums who had been certified for more than five years; and if he would give the figures of those who had been in asylums for ten years and upwards—Mr. WILLIAM WHITELEY replied on behalf of the Minister of Health: Statistics collected by special inquiry in 1921 showed that on Jan. 1st. in that year there were 43,871 male and 55,883 female patients under care in institutions for the insane in England and Wales. Of these, 14,058 men and 19,202 women were described as married, of whom 7,121 men and 10,801 women had been certified for more than five years. Information in regard to married patients who have been under care for ten years and upwards is not available.

Rent Restriction Act and Slum Clearance.

Dr. LITTLE asked the Minister of Health whether his attention had been called to the inquest conducted by the City coroner on Nov. 20th, 1929, on a death occurring in Clerkenwell slum property, where a tenement comprising six small rooms, occupied by 23 men, women, and children, could not be demolished and rebuilt by the owners by reason of the Rent Restriction Act; and whether he was prepared to introduce legislation, by way of amendment of the Rent Restriction Act, in order to provide that, where the owner of property bona fide desired to pull down the same for rebuilding, for commercial purposes or otherwise, he should be entitled to an order for possession, subject to his providing reasonable alternative accommodation for the displaced occupiers.—Mr. GREENWOOD replied: The answer to the first part of the question is in the affirmative. In reply to the second part, I would point out that existing legislation provides that an order for possession may be granted by the Court when a dwelling-house is reasonably required for any purpose which, in the opinion of the Court, is in the public interest, and the Court is satisfied as to the existence of alternative accommodation, and that it would be reasonable to grant the order.

TUESDAY, DEC. 17TH.

Deaths from Cancer.

Mr. FREEMAN asked the Minister of Health the average number of deaths from cancer during the last 10 years, and whether there had been any substantial increase or decrease recently.—Miss SUSAN LAWRENCE (Parliamentary Secretary to the Minister of Health) replied: Particulars of cancer deaths and mortality-rates in each of the last ten years will be found in the Registrar-General's Statistical Review for 1928, Part I., Tables 4 and 5 on pages 10 and 24–25, and in the Chief Medical Officer's Report for 1928, pages 167–175. With regard to the latter part of the question, so many factors are involved in any discussion of the tendencies of mortality from this cause that I can only refer the hon. Member to the commentary upon the subject which is annually contained in the Text Volume of the Statistical Review, and of which the last example will be found commencing on page 58 in the Text Volume for 1927.

National Health Insurance Fund.

Mr. REMER asked the Minister of Health the amount paid into the National Health Insurance Fund by employers and employees during 1928.—Mr. GREENWOOD replied: The amount paid into the National Health Insurance Fund during 1928 in respect of contributions by employers and employees in England and Wales was £23,187,000, of which it may be estimated that the employers' share was approximately £11,703,000 and the employees' share £11,394,000.

Medical and Health Services in Uganda and Kenya.

The Duchess of ATHOLL asked the Under Secretary of State for the Colonies how many village dispensaries and maternity centres for the use of natives were now in existence in the Protectorate of Uganda; how many trained native midwives were now on the roll in that Protectorate; how many were trained annually by the Government, the Church Missionary Society, and the Third Order of St. Francis, respectively, in Uganda; and whether he proposed to suggest to the Government of Kenya that they should establish a scheme similar to that in Uganda for the provision of trained native midwives for the natives of Kenya.—Dr. SHIELS replied: The latest information available in the Colonial Office relates to the year 1928. There were then 66 district sub-dispensaries in the Uganda Protectorate in addition to 21 native hospitals at which dispensary treatment could be obtained and 41 maternity centres. Four new maternity centres were in course of construction. There were 93 native midwives on the official midwives roll on Jan. 1st, 1929. In 1928 the average number of student midwives in training by the Church Missionary Society was 24, and 15 passed the qualifying examination during the year. At the Mill Hill Mission, where the sisters of the Third Order of St. Francis work, the average number of students was 21 and three natives qualified. The Protectorate Government contributes annual grants to missions for the maintenance of midwifery centres and midwives. As regards the last part of the question, steps have already been taken in the matter in Kenya by the Government and by voluntary effort. At the end of 1928 there was a number of child welfare clinics in operation in Nairobi, Mombasa, and Kisumu, and additional centres were to be opened in Mombasa this year. The Lady Grigg Child Welfare League has maternity homes and child welfare centres in Nairobi and Mombasa. The training in midwifery of Indian and native women is undertaken at these centres.

BRISTOL HOMŒOPATHIC HOSPITAL.—Miss Wills last week opened a new children's ward at this hospital which has been given by Mr. and Mrs. W. Melville Wills. The hospital was originally built and equipped by Mr. and Mrs. Wills as a memorial to their son.

SCUNTHORPE AND DISTRICT WAR MEMORIAL HOSPITAL.—This hospital, which has cost £65,000, was opened last week by Mr. Talbot Cliff who, with his uncle, the late Mr. Stephen Cliff, has been a large benefactor to the institution. It replaces the existing Frodingham Cottage Hospital and contains 72 beds; the complete scheme provides for 112 beds.

ST. BARTHOLOMEW'S LIGHTHOUSE.—The lighthouse on the top of St. Bartholomew's Hospital, the beams of which remind London that an appeal is being made for a fund of a million, is mounted on the roof of the new surgical and operation block, about 120 feet from the ground. The lamp is a Philips 5000 watt, 500 volts of standard type. The candle-power of the beam is estimated at 750,000, and the light has been seen as far away as Bedford.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of the Council was held with Lord Moynihan, the President, in the chair, on Dec. 12th, when the Fellowship of the College was conferred on the following:—

Mani Shanker Khushaldas Joshi, Bombay and St. Bart.'s; Robert Malcolm Dannatt, St. Bart.'s and London; David John Jones, Cardiff and Westminster; Griffith John Griffiths, Cardiff and Middlesex; Edgar Frederick King, Bristol; James Ivor Griffiths, Cardiff and Univ. Coll.; Ambrose John King, London; Noel Ellis Laurence, St. Bart.'s.; Harry Vernon Wells, Charing Cross; Arkyl Staveley Gough, Guy's; John Francis Edward Gillam, St. Thomas's; Howard Livingstone Peake, Guy's; Frank William Law, Middlesex; Beatrice Gwendoline Smith, Univ. Coll.; John McNeill Milloy, Glasgow and London; Jack Gardiner Wigley, Cambridge and St. Thomas's; William Pickup Greenwood, St. Bart.'s; Allan Warren Linford Row, St. Bart.'s; Edward McLellan, St. George's; William Charles Wallace Nixon, St. Mary's; Reginald Eric Norrish, St. Bart.'s; Stanley Farrant Russell, St. Bart.'s; Shafik Shalaby, Cairo, London, and King's College; William Elphinstone Underwood, St. Bart.'s; Frank Forty, Univ. Coll.; Mahapitiyage Velin Peter Peiris, Ceylon, London, and St. Bart.'s; William John Hunt Montgomery Beattie, Cambridge and St. Bart.'s; Mohanlal Vanichand Modi, St. Bart.'s; Harry Silvester Waters, Cambridge and St. Mary's; Marcus Cole Rous, Cape Town, London, and Guy's; Harry Teesdale Simmons, Manchester and Guy's; Philip Wiles, Middlesex; Julian Ormond Smith, Melbourne and St. Bart.'s; James Dawson, Glasgow and St. Bart.'s; David Nathan Eppstein, Otago and Guy's; Alfred Laurence Johnston, Melbourne and London; Aubrey James Mason, Otago and Guy's; Arthur Rainsford Mowlem, Otago and London; Leith Alexander Riddell, Otago and St. Thomas's; Arthur Liddon Webb, Adelaide and St. Thomas's; and Frederick Edward Webster, Otago and Guy's.

Diplomas of Membership were granted to Eric Marks (St. Mary's) and Alison J. Rae (Royal Free).

Mr. Cyril H. Howkins, was re-elected a Member of the Board of Examiners in Dental Surgery. Lord Moynihan was re-elected the representative of the College on the Court of the University of Birmingham. The Blackburn and East Lancashire Royal Infirmary and the Hampstead General and North-West London Hospital were recognised for the 12 months' surgical practice required of non-Members before admission to the Final Fellowship Examination. It was reported that Sir Frank Colyer would give two demonstrations on the Odontological Collection on March 12th and 19th, 1930.

With regard to the resolution passed at the Annual Meeting of Fellows and Members on Nov. 21st affirming the desirability of admitting Members to direct representation on the Council, the following reply was adopted:—

> No evidence has been submitted to the Council that the change in the constitution of the College advocated in the resolution is desired by any considerable number of Members of the College, and the Council is therefore not prepared to reopen the question at the present time.

A recommendation from the Board of Examiners in Dental Surgery that a higher dental diploma for licentiates in dental surgery of the College should be instituted was further considered, and it was decided to consult the dental schools regarding the proposal. It was suggested by the examiners that the diploma should, if possible, be called diploma of Fellow in Dental Surgery, F.D.S. R.C.S. Eng., but the consideration of the title to be given to the diploma was deferred.

Primary Fellowship Examination.

At the Primary Examination for the Fellowship, held from Dec. 3rd to 13th, 165 candidates presented themselves and 49 were approved. The following are the names and medical schools of the successful candidates:—

H. J. B. Atkins, Oxford and Guy's; D. A. Beattie, St. Bart.'s; T. H. Berrill, M.B., Bristol; D. D. Boovariwala, M.B., Bombay and King's Coll.; J. T. Chesterman, M.R.C.S., Bristol, King's Coll., and Middlesex; H. O. Clarke, M.B., Dublin and Middlesex; Dorothy J. Collier, M.B., Oxford and King's Coll.; S. B. Cooper, M.B., and K. K. Dalal, M.B., Bombay and London; F. F. D'Arcy, M.S., Melbourne, King's Coll., and St. Mary's; N. D. Fadia, M.B., Bombay and King's Coll.; B. W. Fickling, King's Coll.; K. J. Gilchrist, Guy's; W. G. Gill, Cambridge, Guy's and King's Coll.; F. J. S. Gowar, Middlesex; A. J. Grace, Saskatchewan and Oxford; L. Greenfield, London; I. A. Hamilton, M.B., Adelaide, King's Coll., and Middlesex; Hariharan, M.R.C.S., Madras and King's Coll.; K. H. C. Hester, London; J. C. Hogg, B.Chir., Cambridge and St. Bart.'s; D. T. Ishmael, St. Bart.'s; E. Jacobson, M.R.C.S., London; Katherine M. Jones, Lond. Sch. Medicine for Women; R. A. Jones, Cambridge and London; G. S. Kelkar, M.B., Bombay and Middlesex; A. W. Kendall, M.B., King's Coll.; M. L. Kennedy, M.B., Dublin and Guy's; V. J. Kinsella, M.B., Sydney, King's Coll., and St. Mary's; R. S. Lewis, Cambridge and Univ. Coll.; K. Lumsden, M.B., Edinburgh and Middlesex; J. Mark, M.B., Otago and King's Coll.; S. N. Mathur, M.B., Lucknow, King's Coll. and Guy's; C. B. Melville, M.B., Melbourne, Middlesex, and King's Coll.; Gertrude M. B. Morgan, M.D., Cambridge, St. Mary's, and King's Coll.; H. F. Moseley, McGill and Oxford; W. Mushin, London; R. W. Nevin, Cambridge and St. Thomas's; *T. H. Parkman, King's Coll.; R. G. Pulvertaft, Cambridge* and St. Thomas's; J. R. Ratcliffe, M.R.C.S., Guy's; B. C. Rennie, M.B., Otago, King's Coll., and St. Mary's; V. C. Snell, Cambridge and St. Bart's; H. H. Stewart, M.D., Melbourne and Middlesex; G. O. Tippett, M.R.C.S., St. Thomas's; A. G. Williams, M.B., Cardiff and St. Bart.'s; H. M. Williams, St. Bart.'s; B. Willinsky, M.D., Toronto and Univ. Coll.; and D. S. P. Wilson, M.B., Dublin and Middlesex.

UNIVERSITY OF LONDON.—At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B., B.S.

Honours.—R. K. Bowes (*c*, *e*), Univ. of Liverpool; C. R. E. Freezer (*b*), Guy's Hosp.; Archibald Gilpin (*a*), King's Coll. Hosp.; D. H. Haler (*b*), King's Coll. Hosp.; Harry Temkin (*a*) Univ. Coll. Hosp.

(*a*) Distinguished in medicine; (*b*) in pathology; (*c*) in forensic medicine; (*e*) in midwifery.

Pass.—H. W. Applin, Guy's Hosp.; C. B. Bloom, London Hosp.; E. J. C. Bockett, King's Coll. Hosp.; A. M. Boyd, St. Bart.'s Hosp.; Bertha A. Briant, L.S.M.W.; A. P. L. Cogswell, King's Coll. Hosp.; C. N. Cohen, Guy's Hosp.; Mabel J. Cooke, L.S.M.W.; Philip Dalzell, St. Bart.'s. Hosp.; C. C. Davis, Univ. Coll. Hosp.; G. H. Dobney, Middlesex Hosp.; C. J. East, St. Bart.'s. Hosp.; Lilian P. Edwards, L.S.M.W.; Muriel F. M. Evans Charing Cross Hosp.; M. J. Evans, St. Bart.'s Hosp.; A. D. Everett, St. Bart.'s Hosp.; B. M. Fonseka, Middlesex Hosp.; R. A. Furniss, Univ. of Liverpool; F. W. Gilbert, Guy's Hosp.; Alice E. N. Gilby, L.S.M.W.; Sibyl D. Goodwill, King's Coll. Hosp.; D. R. Griffith, St. Thomas's Hosp.; Grace M. Griffith, Univ. of Leeds; T. R. Griffiths, St. Bart.'s Hosp.; R. W. Haines, Univ. Coll. Hosp.; Margaret L. Hamburger, L.S.M.W.; E. O. Harris, Middlesex Hosp.; C. V. Harrison, Welsh National School of Medicine and Univ. Coll. Hosp.; G. F. Harrison, St. Thomas's Hosp.; G. B. M. Heggs, St. Mary's Hosp.; E. A. H. Hingbaugh, London Hosp.; R. C. Holderness, Univ. of Leeds; G. MacI. Houston, Guy's Hosp.; Simon Kin, *King's Coll. Hosp.; R. A. King, St. Mary's Hosp.*; K. E. Lane, Guy's Hosp.; L. P. E. Laurent, Univ. Coll. Hosp.; F. J. G. Lishman, Univ. Coll. Hosp.; Dorothy M. Lufkin, Univ. Coll. Hosp.; Gladys E. McCabe, L.S.M.W. and St. Mary's Hosp.; J. F. Mackenzie, Guy's Hosp.; J. R. A. Madgwick, London Hosp.; E. W. Martindell, Univ. Coll. Hosp.; Olive M. Midgley, L.S.M.W.; T. H. Nogus, St. Thomas's Hosp.; Doreen G. C. Nixon, Univ. of Bristol; Penelope A. Peach, L.S.M.W.; L. M. J. A. Pilot, St. George's Hosp.; N. E. Pitt, Guy's Hosp.; Raymond Purvis, St. Thomas's Hosp.; Sylvia M. Ransford, L.S.M.W.; N. W. Roberts, Univ. of Liverpool; W. P. Roe, Guy's Hosp.; Harry Selby, Guy's Hosp.; Rupert Shelley, St. Thomas's Hosp.; R. C. N. Shires, Univ. of Leeds; Samuel Shone, Guy's Hosp.; A. W. E. Soyes, King's Coll. Hosp.; Marjorie V. N. Sudds, L.S.M.W.; C. B. V. Tait, St. Bart.'s Hosp.; S. A. Underwood, St. Mary's Hosp.; L. E. Vine, Univ. of Bristol; W. H. S. Wallace, St. Thomas's Hosp.; Eileen A. L. Webb, L.S.M.W.; J. W. Wigg, Univ. Coll. Hosp.; E. M. Wijerama, Ceylon Med. Coll. and Univ. Coll. Hosp.; R. M. Williams, Guy's Hosp.; C. S. Wise, St. Bart.'s. Hosp.; H. S. H. Wood, Middlesex Hosp.; N. R. W. Wynn-Williams, Middlesex Hosp.

The following have passed in one of the two groups of subjects:—

Group I.—Kathleen L. Bland, Univ. Coll. Hosp.; Arnold Clark, St. Bart.'s Hosp.; T. V. Cooper, Westminster Hosp.; C. H. Dale, *St. Bart.'s Hosp.; H. B. A. R. Densham, Guy's* Hosp.; R. L. H. Harris, St. Bart.'s Hosp.; A. G. Harsant, London Hosp.; D. T. Jones, Guy's Hosp.; H. W. Jordan, Univ. Coll. Hosp.; Laura H. Macfarlane, L.S.M.W.; H. G. McGregor, Guy's Hosp.; F. M. Mallinson, Univ. Coll. Hosp.; C. E. H. Maycroft, Guy's Hosp.; L. H. Mottet, Univ. Coll. Hosp.; C. M. Ockwell, Guy's Hosp.; G. F. Peters, Guy's Hosp.; E. S. Pope, St. Bart.'s. Hosp.; Barkat Ram, St. Thomas's Hosp.; A. C. Riley, St. Bart.'s. Hosp.; N. L. Sheppard, King's Coll. Hosp.; Helana Sidarous, L.S.M.W.; Brian Stanley, Univ. Coll. Hosp.; Harris Teitelbaum, Welsh National School of Medicine.

Group II.—E. F. D. Baker, St. Bart.'s. Hosp.; R. C. Bennett, St. Bart.'s Hosp.; P. C. C. de Silva, King's Coll. Hosp.; F. A. Edwards, St. Bart.'s Hosp.; J. D. S. Flew, Univ. Coll. Hosp.; H. S. Hamlin, St. Thomas's Hosp.; K. W. D. Hartley, St. Bart.'s Hosp.; H. B. Hodson, St. Thomas's Hosp.; A. S. Hosseason, St. George's Hosp.; John Ives, St. Mary's Hosp.; A. H. M. McMullan, Univ. of Birmingham; Robert Machray, Westminster Hosp.; J. R. Murray, London Hosp.; R. K. Price, St. Bart.'s Hosp.; Everoll M. Shippam, L.S.M.W.; C. E. H. Turner, London Hosp.; R. C. Williams, St. Thomas's Hosp.

L.S.M.W.—London (Royal Free Hospital) School of Medicine for Women.

A HOSPITAL FILM.—A film has been made of the work of Birkenhead General Hospital, and will be shown at various cinemas in that town during the next two or three weeks.

UNIVERSITY OF BIRMINGHAM.—At recent examinations the following candidates were successful:—

M.D.

* J. W. Field and C. J. Polson.

M.B., CH.B.

T. A. Cooper, G. J. Garratt, I. B. Gumede, R. H. Hucknall, E. J. Kerr, E. J. Mann, P. H. Merlin, Ahmed Monib, J. D. W. Shedden, and Mary A. Tomlinson.

* With honours.

FINAL EXAMINATION FOR L.D.S.

W. J. Bate, N. L. Cookson, A. A. Dessouki, Boyce Douglas, R. J. Godfrey, W. B. Hales, B. J. O'Meara, D. A. Parsons, F. H. Richards, A. J. Simcox, A. E. Thomason, S. G. Watson, and W. B. Wood.

UNIVERSITY OF MANCHESTER.—At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B. AND CH.B.

*Edith M. Booth, *F. N. Marshall, Alexander Allan, Hedley Boardman, R. O. Brooks, J. A. K. Brown, Christobel M. Hall, W. H. Harris, E. J. B. Sewell, and Nellie Wilson.

* Second-class honours.

Part I.—G. M. Lendrum.

FINAL EXAMINATION FOR B.D.S.

W. L. Lilley.

FINAL EXAMINATION FOR L.D.S.

W. J. Brown, and Norman Wild.

MEDICO-LEGAL SOCIETY.—The annual dinner of this Society was held at the Holborn Restaurant on Dec. 13th with the President, Lord Riddell, in the chair. Dr. Nathan Raw, in proposing the health of Medicine and Law spoke cordially of the work of the Medical Research Council and maintained that our lunacy administration was the best in the world. Lieut.-Colonel C. T. Samman, Master of the Apothecaries Company, replying for Medicine, contrasted the solid rock of the law with the fluidity of constantly changing medicine; the two professions touched at many points and had in common that they treated their clients' secrets as confidential and did not advertise. He suggested that the enormous increase in the use of opium and cocaine, due to the hectic and intensive life of the younger generation, called for the coöperation of both professions. Mr. A. E. Mitchell-Innes, K.C., replying for Law, compared medicine and law in that the object of both was to remove inflammation and restore the temperature of patients to normal. The main propositions of law had to be fixed and definite in character; he envied the medical profession the picturesque and much more highly coloured region of theory in which they enjoyed themselves. The barrister got back a little of his own when he demanded "a definite answer—yes or no" of the expert witness, but the speaker had never heard a competent expert witness fail to destroy the effect of the "yes" or "no" by his subsequent categorical explanation. He thought that the time might come when the well-known definition of insanity now acted upon in the courts would have to be adjusted. Progress in that direction would only be achieved by the best efforts of the best minds in both professions. Lord Greenwood, proposing the toast of the Medico-Legal Society, said that law and medicine represented the two indispensable foundations of the civilised state. The medical profession had no frontiers; but lawyers were localised in accordance with the civilisation in which they operated. The medical profession was the only one with a common ideal and common ground, and was freer than any other from the superstitions and fears that held back mankind. Lord Riddell, replying, said he had a great respect for great professions and compared himself with the old lady who always bowed when the name of Satan was mentioned. "Civility costs nothing," she said, "and you never know what may happen." The Medico-Legal Society's Latin maxim could be rendered, "Truth lies wrapped up and hidden in the depths." This applied to science, medicine, and above all to legal proceedings. The Society had been started by coroners with a view to assisting in the discovery of truth. Its main object was to provide weapons to enable doctors and lawyers to discover truth; sometimes they picked up golden nuggets and at other times dead cats. The badge of the Society depicted a well, on either side of which stood Sir Bernard Spilsbury and Sir William Willcox, looking very intently into the well, Truth being at the bottom, while the President and Members of the Society stood in the offing looking very anxious. Replying to the toast of The Guests, proposed by Sir John Collie, the Attorney-General, Sir William Jowitt, said that the administration of criminal law depended not only upon the doctors and the lawyers but also upon the press. Many years ago he had thought it a most essential reform that trials for blackmail should be held in camera; this reform had been brought about without any Act of Parliament, simply by the good sense of the press. Speaking of the system of coroners' inquests, he reminded the audience that it was much easier to destroy a system than to build it up. The coroners' system went back to dim antiquity. The fact that coroners conducted over 30,000 cases a year and that the public demand for the abolition of the system related to only two or three cases, proved how extraordinarily well coroners conducted the very useful work entrusted to them. Mr. Donald Armour, also replying, said that, although the son of a chief justice and a member of a very large legal family, he had been attracted to the senior profession of surgery—senior, because the first operation on record (a rib resection) had preceded the first legal quarrel as to who had actually purloined the apple in the Garden of Eden. The Medico-Legal Society could play a great part in the education of the two professions, for the majority of doctors were notoriously bad witnesses, while all lawyers were hopelessly ignorant of everything pertaining to the practice of medicine and the art of surgery. The doctor had to be taught to answer questions about what he knew and the lawyer to ask questions about that of which he knew nothing.

DONATIONS AND BEQUESTS.—Mr. R. S. Belfield, of Hawkhurst, Kent, left nearly £31,000 on the death of his wife to be divided among a number of charities, 5 per cent. being allotted to the Royal Hospital and Home for Incurables, Putney, 5 per cent. to the Tunbridge Wells General Hospital, and smaller percentages to various other hospitals and nursing associations.——Among other charitable bequests Mr. G. Strachan, of Glasgow, left to the Glasgow Royal Infirmary, the Glasgow Western Infirmary, and Glasgow Victoria Hospital £1000 each, and a sum for the endowment of beds; and to the Glasgow Eye Infirmary, the Princess Louise Hospital for Limbless Sailors and Soldiers, the Ralston Auxiliary Hospital of the Scottish Branch of the Red Cross Society, and St. Dunstan's Hospital for Blind Sailors and Soldiers, £500 each. To Glasgow Royal Hospital for Sick Children, £500, and to endow beds an additional £1500; to the Royal Samaritan Hospital for Women, Glasgow, and the Glasgow Royal Cancer Hospital, £500 each; and to the Elder Cottage Hospital, Govan, Glasgow, £1000, and to endow beds an additional £1500.—Mr. William Anderson, of Aberdeen, left £1000 each to the Aberdeen Royal Hospital for Sick Children, the Aberdeen Nursing Association, and the Convalescent Home, Cults; £500 to the Aberdeen Maternity Hospital; and £250 each to the Morningfield Hospital, Aberdeen, and the Aberdeen Asylum for the Blind.

Appointments.

BINGHAM, T. H., M.D., B.Ch. Belf., D.P.H., has been appointed Assistant Medical Officer of Health and School Medical Officer for Ealing.

KERR, J. A., M.D., Ch.B. Glasg., D.P.H., Assistant Medical Officer of Health, Birmingham.

MCLEOD, J., M.B., Ch.B. Edin., D.P.H., Assistant Medical Officer of Health for Motherwell and Wishaw.

ROBERTS, J., M.B., Ch.B. Liverp., F.R.C.S. Eng., Hon. Assistant Laryngologist to the Liverpool Royal Infirmary.

STENHOUSE STEWART, D. D., L.R.C.P. Lond., M.R.C.S., Honorary Assistant Ophthalmic Surgeon to the Hull Royal Infirmary.

WHEELER, E. R., F.R.C.S. Eng., to be one of the Medical Referees under the Workmen's Compensation Act for the districts of the Bath, Calne, Chippenham, Devizes, Frome, Hungerford, Malmesbury, Marlborough, Melksham, Newbury, Swindon, Trowbridge, and Warminster County Courts.

Birmingham Children's Hospital: ROSSER, MARGARET, C., M.B., Ch.B. Birm., House Physician; STAMMERS, F. A. R., M.B., Ch.B. Birm., F.R.C.S. Eng., Surgeon to Out-patients; and TATE, B. C., B.Chir. Camb., M.R.C.P. Lond., M.R.C.S., Physician in Charge of the Skin Department.

Certifying Surgeons under the Factory and Workshop Acts: HUGHES, E. R., L.R.C.P. Lond., M.R.C.S. (Holyhead); SCARBOROUGH, O. L., L.R.C.P. Lond., M.R.C.S. (Selby); and SIM, T., M.B., Ch.B. Glasg. (Ryde).

The Radium Institute: SMITH, A. J. DURDEN, M.B., B.S., Assistant in the Medical Department; and WILKIN, W. J., B.Chir. Camb., House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Barnstaple, North Devon Infirmary.—H.S. At rate of £150.

Birmingham General Hospital.—H.P. and Two H.S.'s. Each £70.

Birmingham, Monyhull Colony, King's Heath.—Res. Asst. M.O. £250–£350.

Birmingham, Selly Oak Hospital.—Two Cas. O.'s. Each at rate of £200.

Bolton, Townley's Hospital, Farnworth.—Second Asst. M.O. £225.

Bradford Children's Hospital.—H.S. and H.P. Each £120.

Bradford Royal Infirmary.—Res. Surg. O. £250.

Bristol General Hospital.—Two H.P.'s, two H.S.'s, Res. Obstet. O., H.S. to Special Depts. Each at rate of £60. Also Cas. H.S. At rate of £80.

Bristol, Ham Green Fever Hospital, &c.—Asst. Res. M.O. £300.

Burnley, Victoria Hospital.—H. S. At rate of £125.

Bury St. Edmunds, West Suffolk General Hospital.—H.S. £150.

Cairo, Egypt, Giza Memorial Ophthalmic Laboratory.—Pathologist and Bacteriologist. L.E.£1200.

Cardiff, Prince of Wales' Hospital.—H.S. for Crossways Country Branch Orthopædic Hospital. £120.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. At rate of £120 and £100 respectively.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. First Asst. in Out-patient Dept. Also Third Res. H.S. At rate of £75.

Charing Cross Hospital, Strand, W.C.—Non-resident House Anæsthetist.

City of London Hospital for Diseases of Heart and Lungs, Victoria Park, E.—Laryngologist.

Coventry and Warwickshire Hospital.—Res. H.S. £125.

Dudley, Guest Hospital and Eye Infirmary.—Asst. H.S. £150.

Durham County Hospital.—Jun. H.S. At rate of £120.

Durham County Mental Hospital.—Jun. Asst. M.O. £350.

Edinburgh Royal Infirmary, Ophthalmic Dept.—Sen. Clin. Asst. and Clin. Tutor. £145. Also two Clin. Assts. Each £200.

Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.

Great Yarmouth County Borough.—Asst. M.O.H. and Asst. Tub. O. £600.

Hospital for Sick Children, Great Ormond-street, W.C.—Part-time Jun. Cas. O. At rate of £150. Also Clin. Asst. M.O. for Venereal Dept. £1 1s. per session.

Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150. Also H.P. and H.S. Each at rate of £120.

Lancashire County Council.—Asst. County M.O., &c. £800.

Leeds Jewish Herzl-Moser Hospital.—Res. M.O. £100.

Leicester Royal Infirmary.—Hon. Phys. and Hon. Surg.

London Female Lock Hospital, 283, Harrow-road, W.—H.S. At rate of £150. Also Hon. Obstet. Surg.

Manchester, Ancoats Hospital.—Asst. Pathologist. £350.

Manchester, Baguley Sanatorium.—Asst. M.O. £350.

Manchester, Barnes Convalescent Hospital, Cheadle.—Res. M.O. £250.

Manchester Royal Infirmary, Roby-street.—Jun. H.S. and Cas. O. £100.

Miller General Hospital, Greenwich-road, S.E.—H.P. and H.S. Each at rate of £125.

Newark Hospital and Dispensary.—Res. H.S. At rate of £160.

Northampton Education Committee.—Asst. School Dentist. £450.

Queen Mary's Hospital for the East End, E.—Hon. Asst. S.

Redruth, Cornwall, West Cornwall Miner's and Women's Hospital. Res. M.O. £200.

Rochdale Infirmary and Dispensary.—Jun. H.S. £175.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.

St. John's Hospital, Lewisham, S.E.—Radiologist.

St. Mary's Hospital, W.—Asst. Pathological Chemist. £300.

Sheffield, Jessop Hospital for Women.—Two Asst. H.S.'s. Each at rate of £100.

Sheffield Royal Infirmary.—H.P., H.S., Ophth. H.S., Asst. Ophth. H.S., and Asst. Cas. O. Each at rate of £100.

Shrewsbury, Royal Salop Infirmary.—Res. H.S. and Res. H.P. Each at rate of £160.

Southampton County Borough.—School Dentist. £450.

Stafford, Staffordshire General Infirmary.—H.S. and H.P. At rate of £200 and £150 respectively.

Swansea County Borough.—Asst. M.O. £600.

University College Hospital, Gower-street, W.C.—Registrar at Royal Ear Hosp. £50.

University College Hospital Medical School, University-street, W.C.—Asst. in Obstetric Unit. £250.

Walsall General Hospital.—Cas. H.S. At rate of £120.

Warrington Infirmary and Dispensary.—Anæsthetist. £105.

West Hartlepool, Howbeck Infirmary.—Asst. Res. M.O. £300.

West London Hospital, Hammersmith-road, W.—Asst. Dental. S.

Westminster Hospital, Broad Sanctuary, S.W.—House Anæsthetist. At rate of £100.

Winchester, Royal Hampshire County Hospital.—Sen. Res. M.O. £200.

THE Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Camberwell.

Births, Marriages, and Deaths.

BIRTHS.

BAIRD.—On Dec. 8th, the wife of Dr. J. C. H. Baird, Southampton-street, Reading, of a daughter.

WOOKEY.—On Dec. 8th, at Hendon, the wife of Eric E. Wookey, M.C., L.D.S. R.C.S., of a daughter.

DEATHS.

ALEXANDER.—On Dec. 9th, suddenly, at Gatefield House, Faversham, Sir Sidney Alexander, aged 60.

BARNARD.—On Dec. 13th, at King's College Hospital, after an operation, Walter Burrows Barnard, L.R.C.P., L.D.S., of Larpent-avenue, Putney.

HALL.—On Dec. 10th, at Woodways, Carbone Hill, Cuffley, Robert Mills Hall, O.B.E., M.B., C.M. Edin.

THOMSON.—On Dec. 10th, at St. James's-square, Bath, David Thomson, V.D., M.D., C.M., aged 85 years.

TUKE.—On Dec. 7th, suddenly, in Cheltenham, Lieut.-Colonel Arthur William Tuke, I.M.S. (retired) of "Stockwell," Cleevehill, aged 58.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

VOCATIONAL GUIDANCE.

AT a meeting of the London Association of the Medical Women's Federation, held on Nov. 20th, Miss F. M. Huxley took the chair, and an address on Vocational Guidance was given by Prof. Winifred Cullis. She gave an account of the establishment of the National Institute of Industrial Psychology, which grew out of the Fatigue Research Committee constituted during the war, and showed how valuable the Institute was proving at the present time, demonstrating the importance of the psychological factor in industry and its application to the workers in individual firms. The work done by the Institute was paid work, but no profit was made, for the balance was used for research. The advice of the Institute had been sought for various reasons—because of lessened output, and, on behalf of a firm of caterers, because of excessive breakages by the workers. By the correction of details of little apparent importance in routine work and by skilled observation of the workers, most dramatic improvements had been effected. As a natural outcome of the work of the Institute help was given to individuals in vocational selection, and tests had been devised which would show whether a prospective worker had a special aptitude for a given type of work. This was of great value, for otherwise haphazard and unscientific methods of selecting workers were employed. The head of a large dressmaking firm told one of the investigators that she always looked at the hands of prospective employees and if she noticed the nails were bitten she preferred not to engage the girl as she would probably prove to be bad tempered; the head of a rival firm said she used this same observation as a rough method of selection, but she showed a preference for candidates with bitten nails since they were often more artistic than the others. Vocational selection tests would show only whether a person was fitted for one particular type of occupation. The system had now been extended to embrace a scheme of vocational guidance, whereby an all-round examination would test both the innate intelligence of an individual and those qualities which cannot be tested by a written examination, the assessment of which is of great importance in determining the type of occupation for which an individual would be most suited. Experimental work on a large scale had been done on a group of elementary school-children. Two hundred children leaving school were chosen, 100 of whom were tested and advised as to the type of occupation in which they would do best. Wherever possible these children took up the suggested work. The other 100 children were not tested, and did not take up selected work. At the end of two years it was found that the children in the guided group had changed their occupation on an average twice, and those in the unguided group four times. The average wage in the guided group was considerably higher than in the other.

A further group of 600 children was being investigated at the present time, and there was scope for work on children from the secondary and public schools where individual choice of occupation was less influenced by economic pressure. The ages at which the tests were found to be of most practical use were from 16 to 18. The value of the vocational guidance tests was shown by some recent examples of individuals who had come to the Institute for help in choice of a career. One girl who had always been regarded as a dreary and eminently unsatisfactory child proved to be one of the most brilliant people ever tested. She was advised to go to a university if possible, and after six months' work she won a scholarship at Oxford where her latent abilities are having full scope, and the correctness of the Institute's estimate is being proved. Another girl who had already matriculated was found to be mentally aged about 10, and she was told that she would probably not do well in one of the learned professions. A boy destined to be a farmer was found to have an astonishing flair for colour and texture combined with great personal charm and a gift for handling men, and he had adopted a career where these would have fuller scope than on a farm. By making a more extensive use of these vocational guidance tests there would be fewer round pegs in square holes, and the sum of the world's happiness would be appreciably increased.

In reply to a question Prof. Cullis emphasised the effect of the speed at which a piece of work was done on the quality of the individual worker's output. When the rate of work was easily within a worker's capacity, A would work well and B would be bored and consequently work less well. By making the work harder B would do better but a strain would be put on A, and the practical difficulties of getting the optimum output from both A and B on the same work were considerable. Workers could be divided into "sprinters" and "stayers" and it was important to find the type of work for which each was suited.

ANCIENT EGYPTIAN MEDICINE.

THE learned author of a little book[1] entitled "Magician and Leech," is convinced that most of the accounts of Egyptian medicine published in medical histories are in need of revision. All down the ages the search has continued for means of prolonging life and averting death; the magician with his spells, the astrologist with his horoscopes, the alchemist with his search for the philosopher's stone, and the medical researcher of to-day with his up-to-date armamentarium, all follow the same quest.

Mr. Dawson, who is well known as an authority on ancient Egyptian medical texts, gives an interesting account of the lengthy process of making a mummy, and, incidentally, refers to the importance of the knowledge of human anatomy acquired thereby by the ancient embalmers. The medical papyri of Egypt antedate the earliest records of any other country by thousands of years; they are epitomised here in eight sections, while reference is also made to later manuscripts, such as the *London-Leiden Magical papyrus* and to Coptic texts. As a result of mummification "Egypt made it possible for the Greek physicians of the Ptolemaic age to begin, for the first time, the systematic dissection of the human body, which popular prejudice forbade in all other parts of the world" (Elliot Smith). During the process of mummification, the heart attached to its great vessels was almost invariably left in situ. Surgical instruments have been discovered, splints were used for fractured limbs, but there is no evidence that tooth-stopping, or any other form of dental surgery, was practised by the Egyptians in Pharaonic times. Mummies, with evidence of Pott's disease, have been discovered and statuettes of achondroplastic dwarfs. A short chapter introduces us to the drugs in general use; those derived from the animal kingdom can mostly be identified, but only a relatively small proportion of the very large number of vegetable drugs used are known. The book ends with a chapter on the survival of ancient medicine, containing an interesting account of the measures recommended to be taken to discover if a woman were pregnant or not, and if the unborn child was to be a boy or a girl.

The work is excellently printed and will be an acquisition to the library of one interested in medical history.

"FISGARD."

To the Editor of THE LANCET.

SIR.—"Etymologist's" query is answered by the subjoined quotation from the late Prince Louis of Battenberg's "Men-of-War Names" (Stanford, London, second edition, 1908, pp. 20), of which there is a copy in the Library of the Royal United Service Institution:—

"*Fisgard* (3d since 1797), originally *Fishguard*.—On Feb. 22, 1797, a French squadron of four vesels landed in Fishguard Bay, Pembroke, some 1300 criminals, armed and dressed as soldiers, with orders to ravish the country, destroy Bristol, and attack Liverpool. They were speedily captured by the Sea Fencibles, Militia, and Yeomanry, led by the first Lord Cawdor. Tradition says that the Frenchmen mistook the Welsh women, who accompanied the local forces in their tall hats and red cloaks, for additional soldiers. On March 9 the *San Fiorenzo* (36) Capt. Sir Harry Neale, and the *Nymphe* (36) Capt. J. Cooke, fell in with the *Résistance* (40) and the *Constance* (22) two of the above-mentioned French squadron, on their way back to Brest, and captured them. The *Résistance* was added to the Royal Navy under the name of *Fishguard*, later altered to *Fisguard*."

From Fishguard (Pembroke) steamers run to Rosslare Harbour (Wexford), and it was at one time attempted to make Fishguard a terminal port for transatlantic passengers

I am, Sir, yours faithfully,

Dec. 16th, 1929. SEA CAPTAIN.

HEALTH OF WEIHAIWEI.

IN a report for 1928 prepared by Mr. R. F. Johnston, the Commissioner, it is recalled that the leased territory of Weihaiwei, which has been administered by Great Britain since 1898, is situated in the north-east corner of the Chinese Province of Shantung, about 40 miles east of the treaty port of Chefoo. The area extends to 285 square miles and supports a population which at the last census (in 1921) was ascertained to be 154,177 but is now estimated at about 180,000, the increase being mainly due to the influx of refugees from other parts of the province, who having found the conditions of life intolerable under the gross misgovernment which has prevailed in Shantung during the past few years have been glad to find peace and security and a sympathetic administration under the British flag. There are over 350 villages in the territory, but the only port is a former Chinese village, now the thriving town of Port Edward, which is the administrative centre. The relations between the British authorities and the local Chinese population are said to be friendly and harmonious. The introduction of motor traffic, which had hitherto been absolutely prohibited, was perhaps the most notable and conspicuous innovation witnessed during 1928; there are now regular motor 'bus services from one end of the territory to the other.

Weihaiwei last year fully maintained its reputation as one of the healthiest spots on the Asiatic coast. In the foreign community there was only one death, and this resulted from drowning. The Chinese population suffered during the spring and summer from a rather severe epidemic of diphtheria and slight outbreaks of scarlet fever and measles. The medical officers trace these epidemics to the fact that during the year under review Weihaiwei was the resort of many half-starved refugees from other parts of the province, some of whom were either suffering from disease when they entered the territory or through privation and debility became easy victims to such causes of infection as existed locally.

State Hospitals.

There are three Government hospitals. The largest of them (under the direct superintendence of the British medical officers of the Government) is in Port Edward; the second is on the island of Liukung, where there is a Western-trained Chinese doctor under the supervision of the resident Surgeon-Commander in charge of the Royal Naval Sick Quarters, who holds the additional post of medical officer for the island, under the Civil Administration; the third is at Wên-ch'uan-t'ang in the heart of the territory, 13 miles from Port Edward, which is also in charge of a Western-trained Chinese doctor under European supervision. The total number of patients attending the three hospitals in 1928 was 20,311. This exceeded the number treated in 1927 by 1008. With regard to the locally prevalent disease of kala-azar, the medical officer reports as follows: "Eighty cases were under treatment during the year and they received 1830 injections; antimony tartrate is given intravenously in the majority of the cases, but in young children stibosan is used intramuscularly with good results. Sixty-four new cases were diagnosed, but only 48 returned for regular treatment; injections were given twice a week. The rapid increase in the number of injections indicates the popularity (and success) of the treatment and the faith of the patients in its efficacy, the figures being 796 in 1926, 1307 in 1927, and 1830 in 1928."

For the second consecutive year the territory was used for the purposes of a convalescent camp of 60 beds for the Shanghai Defence Force. Full use was made of this camp during the summer months of 1928 with highly beneficial results. A small sanatorium for the treatment of Chinese cases of tuberculosis—a somewhat prevalent disease in this territory—was established in 1928 near the seashore, about two and a half miles to the south of Port Edward. A new ward for Chinese paying patients was added to the Port Edward Hospital. The first patient to avail himself of this ward was a Chinese General, who, after defeat in a local civil war, became a refugee in Weihaiwei. For the first time in the history of the territory provision was made during 1928 for European patients by the addition of a ward of two beds to the Port Edward Hospital. Accommodation for Europeans in the small adjacent infectious diseases hospital was also made available by enlargement of the existing premises.

Leprosy.

Special interest attaches to the efforts made to deal with cases of leprosy in the territory by the adoption of the new treatment with alepol (intravenal hydnocarpate injections). The actual number of lepers in the territory is not great—official inquiries reveal a total of about 70. The new treatment is freely administered to all lepers, who submit themselves voluntarily to the doctor's hands. At the close of the year there were 15 patients undergoing regular treatment, and in several of these cases a marked improvement has already been noticed. A report (by Dr. Francis Clark, the senior medical officer) has been sent to the British Empire Leprosy Relief Association.

The rainfall during the first half of 1928 was much below the average, being only 3·7 inches. The drought was the cause of the almost total failure of the wheat crop and also gave rise to some anxiety with regard to the water-supply, which is derived from shallow wells. The total rainfall for the year, however, was 22·33 inches. Several additional wells were sunk by Government in the Port Edward area and fitted with pumps; and fears of a water famine were dissipated by the copious rains which began to fall in July. There are two thermal springs in the leased territory, the best known being that situated outside the East Gate of the walled city, on the outskirts of Port Edward, where bath houses were erected many years ago and are still in daily use.

Campbell Oration

ON

PROGRESS IN UROLOGY.

Delivered at Belfast on Nov. 8th

BY ANDREW FULLERTON, C.B., C.M.G.,
M.CH. BELF.,
SURGEON TO THE ROYAL VICTORIA HOSPITAL, AND PROFESSOR
OF SURGERY IN THE QUEEN'S UNIVERSITY, BELFAST;
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS
IN IRELAND.

REMARKABLE advances have been made in urology since those of us who were contemporaries of Robert Campbell were students together. In those days the cystoscope was occasionally shown to us by our teachers as a sort of interesting toy which, like many another piece of apparatus, would in due time find its way to the scrap-heap. While thinking out the subject matter of this lecture, I took up a text-book of surgery in general use in my student days. There is not a word about the cystoscope in the chapters devoted to injuries and diseases of the urinary organs, and I cannot even find the word in the index. To-day we fairly bristle with cystoscopes, and a patient is fortunate if he escapes the ordeal of cystoscopy whatever his complaint.

In tracing the development of urology and the evolution of the cystoscope and urethroscope, frequent reference must be made to the work and writings of two great English-speaking urologists: Hurry Fenwick in England and Hugh Hampton Young in America. It would serve my purpose well if I had time and space to quote word for word the opening chapters of Fenwick's work entitled: "The Electrical Illumination of the Bladder and Urethra,"[1] published in 1889, and a paper by Young entitled: "The Renaissance of Urology,"[2] published in 1916. Young's account of the early history of urology is so full and interesting that I cannot do better than quote freely from it.

UROLOGY IN ANCIENT TIMES.

Urology was perhaps the first branch of surgery practised in ancient times. The inhabitants of India over a thousand years B.C. used the catheter to relieve retention of urine and the sound to dilate strictures. They were also, apparently, quite proficient in the operation of perineal lithotomy. In the Hippocratic writings (400 B.C.) will be found accurate descriptions of the formation of urinary calculi, of lithotomy and nephrotomy—and this at a time when practically no other operations upon abdominal viscera were attempted. By the Hippocratic oath the general practitioner was required to promise never to perform lithotomy, but to leave the operation to those who made a specialty of it. At the beginning of the Christian era operations for calculus, retention of urine, and urinary fistula were well conceived and skilfully performed. During the Middle Ages, while medicine was in the hands of the monks who disdained surgical operations, the practice of surgery was kept alive by the lithotomists. During this time the inhabitants of the town of Norcia, who were skilled lithotomists, were summoned to all parts of Europe and were frequently in the service of municipalities. The operation for stone, which up to this time had been almost entirely in the hands of these itinerant laymen, was finally taken up by the medical profession, through the work of a French surgeon named Germain Colot, about the year 1460. He went to Italy, ingratiated himself with a family of lithotomists, learned their methods and returned to France, where he commenced a series of experiments upon the cadaver, the results of which he reported to the medical faculty of Paris. He then applied to Louis XI. for permission to operate on a criminal condemned to death. Permission being granted, the operation was carried out in the churchyard, in the presence of the King. The patient made a good recovery and Colot was decorated by the King, appointed royal lithotomist, and became the father of a family which furnished France with its chief lithotomists for three hundred years. Although medical men, they kept the secret to themselves, just as the Norcians had done, until François Colot, the last of the family, gave the secret to the medical world in 1727.

General surgeons at this period seemed unable to make a success of lithotomy, so that the operation again passed into the hands of laymen, one of whom, a monk named Frère Jacques, marvellous to relate, invented and introduced the lateral operation for stone which requires far more precision and expert knowledge of anatomy than the median operation which was previously used. The story of Frère Jacques, his meteoric rise at court, the crowds that assembled to see his lightning-like procedures, his admission to the great hospitals of Paris (notwithstanding the protests of the surgeons), and his final departure in disgrace because most of his patients died, says Young, is one of the most thrilling histories of surgical literature. Frère Jacques died in 1720, and his operation, perfected by the English surgeon Cheselden, is notable as being based on the best anatomical principles. To this day the non-medical lithotomist flourishes in the East, and it is extraordinary how major operations in surgery have been largely left to uneducated persons. The famous Ambroise Paré learnt the operation of lithotomy from a Colot, and was one of its most accomplished exponents.

JOHN HUNTER AND AFTER.

Young pays great tribute to John Hunter as a pioneer in genito-urinary surgery. He says: "It was not until John Hunter came that the solid foundations of scientific surgery were laid." It is interesting to note that at that time there were two great surgeons in England, William Cheselden and James Douglas, who owed their reputation chiefly to their operations for stone. Hunter became the pupil of one of these, Cheselden, the author of the present lateral operation for stone, which he was able to perform in 54 seconds. It is very evident from a study of the clinical works of Hunter that his practice was largely genito-urinary in character. It was Hunter's custom to admit young men into his home as pupils, and it is not surprising to find that of these men who afterwards became famous the majority were particularly interested in genito-urinary surgery.

The history of urology in France during the eighteenth and nineteenth centuries comprises the work of almost all the celebrated surgeons of that period. Time will not permit me to mention the work of all who took part in the evolution of urology in France, but certain names, which include Civiale, Mercier, Maisonneuve, Guyon, and Albarran, are familiar to medical students of to-day in connexion with some special operation or some ingenious instrument. The most important invention of this time was that of stone-crushing by Civiale in 1818. Mercier's work on obstruction at the vesical neck and the ingenious instruments he devised were of great importance, but according to Young it was to Civiale first, and later to Guyon, that the medical profession owes most of the solid foundation upon which the superstructure of modern urology has been reared. Sir Henry Thompson in England, a brilliant pupil of Civiale, pursuing the careful research methods of John Hunter in anatomy and pathology, did more perhaps than any one man in the nineteenth century to bring urology into the very forefront of surgery.

It was not until about the middle of the nineteenth century that America, now one of the most progressive schools of urology in the world, began to exert an influence on this branch of surgery. About this time there were several surgeons in America who had achieved great success as lithotomists, and of these special mention must be made of Bigelow, who revolutionised the treatment of vesical calculus. In 1878, at Boston, he began his great work on lithotrity by inventing stronger and more efficient lithotrites and introducing a powerful evacuating bulb by means of which the stone, broken into small fragments, could be completely removed. It may be news to some of us that the name "litholapaxy," by which the operation is now known, was suggested by Oliver Wendell Holmes.

Towards the end of the nineteenth century Austria and Germany entered the field of urological research. About this time Simon of Heidelberg began his epoch-making work on the kidneys. No one knew at this time whether a kidney could be removed with impunity. Simon set to work to solve the problem, and performed nephrectomy in a series of 30 dogs. The results placed the operation on a sound basis. The operation was then carried out with success by Simon in a young woman with a ureteral fistula. This was in July, 1869, and is, so far as I know, the first recorded case of nephrectomy in the human subject. The operation, however, owing to its great mortality, made little progress, so that as late as 1879 Pilcher was able to find only 15 cases in the literature. The reason for the failure of nephrectomy to find a place in surgery was due in the main to sepsis, but the work of Lister in 1867 soon began to exert its influence, and the surgery of the kidney was assured. In 1885 Samuel D. Gross collected 450 cases of operation on the kidney and found the mortality of nephrectomy for various diseases to be between 20 and 60 per cent. The present mortality ranges between 1 and 5 per cent.

MODERN UROLOGY AND THE CYSTOSCOPE.

The period of modern urology was ushered in by the invention of the cystoscope by Nitze in 1876. In 1879 Edison's invention of the incandescent electric bulb paved the way for the perfection of the cystoscope and the accompanying array of ingenious apparatus now at the disposal of the urologist. The first attempt at endoscopy was by means of hollow bone urethral tubes through which sunlight was admitted. The history of vesico-urethral endoscopy is given by Hurry Fenwick in his work entitled "The Electrical Illumination of the Bladder and Urethra," and I will endeavour to give a short abstract of his account of the evolution of the cystoscope and urethroscope.

The first period commenced in 1805 with the invention by Dr. Bozzini of an apparatus which he termed the light conductor. Although the instrument was condemned by the Medical Faculty of Vienna on the ground of insufficient illumination the idea was grasped by the profession and a long list of investigators added to the literature of the subject and attempted to improve the instruments for visual examination of the bladder and urethra. Thus John Fisher of Boston, in 1824, invented a hollow metal tube with a reflected light, Paul Ségalas, in 1826, demonstrated before the Academy of Science of Paris an improved urethro-vesical speculum, and many others suggested and carried out various modifications and improvements.

The second period was opened in 1853 by Desormeaux, who is called "the father of endoscopy." This surgeon brought before the Academy of Medicine at Paris the first practical endoscope, and did much to further the development of the science of endoscopy. In 1865 F. R. Cruise of Dublin[3] made an important improvement in the Desormeaux endoscope. This consisted in concentrating upon a reflector the edge of the flat flame from an ordinary paraffin lamp. The apparatus was provided with specula through which the light from the lamp was reflected to the parts to be examined. To prevent inconvenience from the great heat evolved by the powerful light, the lantern was made of mahogany. The cannula for the bladder resembled a coudé catheter, with a little window of glass at the angle to permit the transmission of light. Various improvements and modifications of this instrument were made, and Christopher Heath used it at the Lock Hospital in London and introduced it to the profession in England in 1866. Beyond certain changes in the reflection of the light from plane or concave mirrors, and in the source of light, the endoscope underwent but little modification until the commencement of the third, or electrical, period in 1879.

The modern cystoscope owes its success to the use of electric light. Bruck of Breslau, a dentist, in 1867, employed a platinum loop, maintained at a white heat by means of a galvanic current, as the source of light for examining the mouth, and even advocated electric light for examination of the rectum and bladder some years before Nitze had his instruments for the urethra, bladder, and larynx sufficiently advanced to be used on the living subject. The original Nitze cystoscope had many failings when it was entrusted to Leiter, the well-known instrument-maker of Vienna, who simplified and perfected the water-cooling arrangements and improved the light. The result was the famous Nitze-Leiter cystoscope of 1879. This instrument, which was at once hailed by medical men from all parts of the world as a great advance in diagnostic methods, had grave faults, which for a time caused it to fall into comparative disuse. It was made in the form of a bladder sound of No. 21 French catheter gauge, with a sharp elbow and a longish beak. Depending on the part of the bladder to be examined, the window was placed in the concavity of the elbow (for the neck, anterior wall and sides) or in the convexity (for the posterior wall and base). The beak carried the electric lamp, and the shaft contained the telescope, the water-cooling tubes, and the insulated wire from the battery to the lamp. The ocular end was furnished with tubes connected with a water reservoir, so that a continuous stream of cold water could be kept running to absorb the great heat emitted by the platinum loop when in action. The ocular end also had a grip or binding screw for the attachment of the connecting cords from the battery. The heat evolved by the platinum loop was so great that a water-cooling apparatus was absolutely indispensable. To obtain the necessary heating and illumination of the platinum wire, an equable, constant current of a certain intensity was necessary. This could only be obtained from a large and cumbersome battery, fitted with a rheostat. The ease with which the platinum loop fused, even in competent hands, required the frequent services of a skilled electrician. Sir Henry Thompson, while demonstrating its use on a patient at the Royal Medical and Chirurgical Society in 1880, said that the instrument "should be under the care of a person well versed in the use of galvanic apparatus, and competent to adjust, or repair if necessary, the very delicate details which formed the essential parts of this somewhat complicated but very complete instrument." In short, the instrument was too cumbersome, too complicated, too unreliable, and too costly to be of general service to the surgeon, and it failed to achieve immediate success.

The next great advance was when the Edison incandescent lamp replaced the platinum loop as a source of light, and the year 1887 marks an era of which the far-reaching importance can hardly be estimated. From this time onward the instrument was improved from time to time until at the present day it is reliable, almost fool-proof, easily portable, cool even after prolonged use, and highly efficient. Every part of the bladder can now be inspected, the ureters can be easily seen and catheterised, and operations of considerable magnitude can be carried out inside the bladder under direct vision, with the minimum of discomfort to the patient. Similarly, the entire urethra can be inspected and treated, the ejaculatory ducts may be catheterised, and various operations, such as the removal of prostatic obstruction, urethral polypi, impacted calculi, and foreign bodies can be carried out with very little risk.

DIFFICULTIES IN CAMPBELL'S TIME.

A young surgeon commencing practice to-day can have no conception of the difficulties that beset those of us who started practice with Robert Campbell in the diagnosis and treatment of urinary complaints. Stone in the bladder was sometimes, but by no means always, detected by the sound. If it was secreted in a diverticulum or lying behind an enlarged prostate or covered with a coating of muco-pus, it was often unsuspected and the patient's misery continued. Tumours of the bladder, innocent and malignant, could not be diagnosed correctly without open operation, and the connexion between bladder symptoms and a lesion in the kidney could only be assumed by the presence of pain or swelling in the loin. It was not at that time fully realised that, in a large proportion of cases, disease of the kidney might not manifest itself by pain or swelling or, at any rate, not until late in the history of the case. When pain or swelling indicated disease of one kidney, the methods of ascertaining the presence and efficiency of a second kidney were crude and often misleading. Before the cystoscope came into general use various methods were employed to obtain the urine separately from the two kidneys. In the following account of these methods I have drawn largely from the article by Schede in Bergmann's "System of Practical Surgery."[4]

Tuchman was the first to obtain the urine separately from the two kidneys. He succeeded in compressing one ureter at a time, the urine from the other being allowed to collect in the bladder, to be drawn off for separate examination. He employed an instrument constructed on the plan of a lithotrite, which when passed into the bladder was made to slip over the elevation surrounding the mouth of a ureter. The blades were then manipulated so as to compress the ureter. The method proved, as might be expected, very uncertain. Silberman proposed the introduction into the bladder, through a catheter, of a thin rubber bag which could be filled with mercury and used to obstruct each ureter separately. The instrument was never perfected. Weir proposed to compress one ureter temporarily by an instrument introduced into the rectum. Ebermann suggested that this compression should be effected by two blades, one passed into the bladder and the other into the rectum.

Other equally useless methods were tried and abandoned. Even after the invention of the catheterising cystoscope, which required considerable practice and dexterity, attempts continued to obtain the urine from each ureter separately by other methods. The principle adopted in these later attempts was to produce an artificial division of the bladder into halves, each half retaining temporarily the urine from the ureter of its own side. Harris, of Chicago, invented an instrument by means of which a longitudinal fold could be produced at the base of the bladder, so as to form a watershed between the openings of the ureters. A lever was passed into the rectum or vagina to produce this fold, and a double catheter was introduced into the bladder. The halves of this double catheter were separated, after introduction, so that each half drained its own side of the bladder. I have used this instrument, but I cannot say that I have found it very satisfactory.

Luys, of Paris, invented a suitably curved, catheter-like instrument across the concavity of which a band of thin rubber could be stretched by means of a chain, manipulated by a screw at the handle. When the instrument was in position the rubber septum was projected by tightening the chain, thus dividing the bladder into halves, the fluid from each half being received into a separate bottle. I have used this instrument many times but I have not been satisfied that admixture across the middle line could be entirely prevented. When the bladder contained blood, pus, or other abnormal material, uncontaminated specimens from the ureters could not, of course, be obtained.

A similar instrument was suggested by Guyon in 1902 and perfected by Cathelin. Through a slit in the convex side of a catheter-shaped instrument a fine spring could be projected. The spring was covered with a thin rubber bag. The septum thus formed could be made to fit accurately the posterior wall of the bladder. Two fine catheters were passed through eyes in the main instrument so as to emerge on either side of the septum. The fact that this instrument was invented in 1902 shows that the catheterising cystoscope had not yet come into general use.

It is said that Simon was the first to succeed in catheterising the ureters. This was done in the female. He dilated the urethra with specula until he could pass his finger into the bladder. He then felt, with his left forefinger, for the little swelling round the ureteral orifice and guided the catheter into the ureter. Pawlik, again in the female, located the position of the ureters by two grooves, seen in the vaginal wall with the patient in the knee-elbow position and the perineum drawn backwards. These grooves are sufficiently distinct to be used as guides for ureteral catheterisation through the urethra. It is said that Pawlik's method was, for a time, the best available and that many successes were obtained.

Howard Kelly[5] was the first to make a useful instrument by means of which the orifices of the ureters in the female could be exposed and catheterised. The method was published in 1893 and was a great advance on all former attempts. The urethra was dilated to accommodate a speculum and the bladder allowed to fill with air. The bladder was lighted by means of daylight or electric light, reflected from a concave frontal mirror. The method was widely employed until it was superseded by the much simpler one of catheterising the ureters through the cystoscope.

Once the principles of the cystoscope had become established, additions and improvements followed with great rapidity until in a few years it became a very efficient aid to diagnosis and treatment. As instrument-makers, Leiter in Vienna, Wappler in America, Löwenstein and Wolf in Berlin, and Collin and Drapier in France, deserve much credit for advances in the construction of the cystoscope.

Those who have grown up with the cystoscope can have no conception of the thrill experienced by one who, accustomed to the older methods of examination, was privileged for the first time to obtain a view of the interior of the healthy bladder by the new instrument. As he viewed the mucous membrane, with its delicate colouring and its beautiful arrangement of vessels, and watched the rhythmic movements of the ureteral orifices which from time to time drew themselves up and ejected a little stream of fluid from their open mouths and subsided gradually into the resting position, he felt that a great vista of opportunity had suddenly burst upon his astonished gaze. As time went on and he became familiar with the normal appearances, he was able to detect in cases of disease alterations in the colour, thickness, and texture of the mucous membrane, blurring and obliteration of the vessels, and changes at the ureteral orifices, the significance of which he had yet to learn. One of the most fascinating pictures with which he now becomes only too familiar is the papilloma, with its finger-shaped processes into which a delicate system of blood-vessels can be traced, forming one of the most beautiful objects in surgery. Stones in the bladder can now be seen with the utmost clearness, their colour, shape, size, position, and number accurately estimated, and even their chemical composition fairly correctly foretold. These and many other abnormalities of the bladder are now diagnosed with the utmost accuracy and precision, suggesting methods of treatment that would have been impossible a few years before.

In the same way the urethra can be examined in its entire length, the presence and degree of stricture determined, the verumontanum and the orifices of the ejaculatory ducts clearly seen, alterations in the colour, resilience and thickness of the mucous membrane definitely displayed, and the state of the ducts and crypts opening into the canal ascertained. To one accustomed to the clumsy methods of the past, such accuracy and refinement of diagnosis beget an enthusiasm impossible to describe. My own experiences when I was suddenly translated from the darkness of precystoscopic days to the light of modern urology, in 1906, were of the most thrilling description, and from this time forward, as new methods were developed and fresh fields discovered, a perennial series of adventures into the newly found paths of cystoscopy and urethroscopy kept me in comparative contentment during the early and lean years of my professional life.

DISEASE OF THE KIDNEYS REVEALED BY THE CYSTOSCOPE.

When the cystoscope became sufficiently perfect and of real practical utility, urologists began to accumulate observations of great interest and importance, so that from visual inspection alone of the bladder and ureteral orifices conclusions of the greatest value could be drawn, not only on the state of the bladder but also on the condition of the kidneys. It was eminently satisfactory to be able to diagnose inflammation and ulceration, the presence of calculi, or other abnormalities of the bladder. But research did not stop here. By careful and repeated observation of the ureteral orifices, their movements and the character of the jets, the surgeon was in many cases able to hazard an opinion on the state of the kidneys. Hurry Fenwick was one of the most brilliant exponents of the art of careful and accurate observation and deduction. His work, entitled "The Value of Ureteric Meatoscopy in Obscure Diseases of the Kidney,"[7] published in 1903, will remain for all time a classic. In the preface he says: "It is not acknowledged—and by many the suggestion is even ridiculed in England—that an electric light illumination of the orifice of the ureter of the diseased kidney can render signal service to the operator. Not only is the bladder declared free from all cause of renal suffering, but the condition of the diseased kidney can be surmised, and the opposite kidney declared healthy or the reverse." Subsequent experience by competent observers has fully justified the claims made by Fenwick. There is no need in these days to labour the point. Every cystoscopist knows that disease of the kidney is very frequently represented in the bladder by easily recognisable changes at the ureteric orifice. In some cases the only objective sign of a disordered kidney is the emission of blood or pus from the orifice of the ureter, and it is well known that this may occur in the absence of pain or discomfort of any kind on the affected side.

The early cystoscope was not provided with a mechanism by means of which the bladder could be irrigated and the medium rendered clear with the instrument in position. This was accomplished more or less satisfactorily about the year 1888. About this time Brenner attempted to catheterise the ureters of females by passing a fine catheter through a tube in an instrument invented by him and made by Leiter of Vienna. He endeavoured to pass the catheter directly into the mouth of the ureter by shifting the whole instrument into a convenient position. In one female he succeeded, but failed in the male subject. Five years later James Brown, Young's predecessor at the Johns Hopkins Hospital, modified the Brenner instrument by passing a curved spring stylet into the ureteral catheter so as to give it the necessary curve for introduction into the ureter, and on June 9th, 1893, achieved the distinction of being the first to catheterise the ureter through the cystoscope in the male subject. Although Nitze was not the first to construct an instrument for ureteral catheterisation, he was the first to construct it on the right principle. In previous instruments the catheter emerged in the long axis of the cystoscope. This made it difficult to direct the catheter into the ureter. Nitze's instrument provided a tube which came off at an angle and directed the catheter towards the ureter when the cystoscope was in position. Casper, in 1895, remedied some of the defects of this instrument and provided means by which the angle at which the catheter emerged from the shaft of the cystoscope could be altered as required. Albarran, in 1897, made an important addition by providing a hinged lever, the position of which could be shifted from the horizontal to the vertical by a screw at the ocular end, thus altering at will the direction of the ureteral catheter. At first, cystoscopes were only provided with arrangements for catheterising one ureter at a time, but soon this was remedied and it was possible to catheterise both ureters simultaneously. It now only remained to improve the lenses, the lamp, and some minor details to render the instrument thoroughly practical and satisfactory for use in patients of either sex. Ureteral catheterisation through the cystoscope soon became a recognised method of diagnosis. This paved the way for the great strides which followed, especially in the treatment of unilateral affections of the kidney. The operation of nephrectomy, instead of being an exceedingly risky procedure, soon became one of the most satisfactory in the whole range of surgery. Allowing for the great improvement in surgical technique which followed the epoch-making work of Lister, a due amount of credit must be given to the attention which could now be paid to the condition of the presumably sound kidney by the ureteral catheter and other methods of investigation. In cases of renal pyuria and hæmaturia the ureteral catheter confirmed the diagnosis made by inspection of the efflux from the ureteral orifices, and in certain cases of albuminuria without pus or blood the condition was located to one kidney. More interesting still is the fact that the urine may be perfectly normal, as shown by chemical and microscopical examination, and yet a lesion may be demonstrated in one kidney by comparing the specific gravity of the specimens of urine taken simultaneously from the two kidneys. For instance, I have seen cases of aseptic renal calculus in which there was no demonstrable abnormality of the urine obtained from the bladder. In certain cases of tumour of the kidney I have seen the same phenomenon, and in hydronephrosis it occasionally happens that the urine, even that obtained by catheter from the affected side, is free from abnormal constituents. I have been interested for many years in the difference in specific gravity on the two sides in unilateral affections of the kidney.[8, 9] Shortly, in a large proportion of cases there is an increased flow of urine of low specific gravity on the affected side. To this phenomenon I have applied the term unilateral diuresis. This sign will be found of great value in diagnosis, especially when the urine obtained from the bladder is normal. A difference of specific gravity on the two sides indicates alteration of function and suggests that the case should be further investigated.

It occasionally happens that for some reason it is impossible to catheterise the ureters through the cystoscope. The bladder may be extensively ulcerated or so irritable that enough fluid cannot be retained, or the medium may be so clouded by blood, pus, mucus, and debris that the ureteral orifices cannot be seen. Various methods to obtain urine from each kidney separately have been devised: Iversen, in 1887, suggested catheterising the ureters through the open bladder; Czerny and Braun employed a temporary fistula of the pelvis of the kidney; Pinner incised the kidney on its convex border, or opened the pelvis and passed a catheter into the ureter for 2 or 3 cm. Other equally unsatisfactory methods have been recommended from time to time. Apparently no one thought of the very obvious and simple method of catheterising the ureters just above the brim of the pelvis, where they can easily be reached by an operation in the iliac region similar to that used for removal of the appendix. In September, 1923, I ventured on this method of approach in a case in which it was found impossible, from bladder irritability and bleeding, to catheterise the ureters. The ureters were exposed and a small incision was made in each to allow of the passage of a ureteral catheter towards the kidney. The small openings in the ureters were closed by fine catgut at the end of the observation and gave no further trouble.[10] It is very gratifying to find that this operation has been extensively adopted by other urologists.

TESTS OF RENAL FUNCTION.

With the march of progress in aseptic technique and in the methods of diagnosis made possible by the cystoscope and ureteral catheter, operations on the kidneys and bladder began to multiply. Surgeons soon found that the kidneys, if at all diseased, were very sensitive to operative interference at any part of the urinary tract. The aid of the chemist, the physicist, the physiologist, and the pathologist was therefore invoked to enable them to assess the functional capacity of the kidney and, if this was *found deficient, to take steps to restore it. Various* tests of renal function were suggested and carried out, with results which have thoroughly justified the enormous amount of research which has been brought to bear on this problem in recent years. Time will not permit me to recount all the methods which have been employed, but a few may be mentioned.

Estimation of the total quantity of urea secreted in 24 hours has not proved very reliable, for the amount varies greatly even under normal conditions.

Koryani and his co-workers found that the determination of the freezing-points of the urine and the blood gave valuable indications of the work being done by the kidneys. The freezing-point varies, of course, with the molecular concentration of the fluid examined. This test is very complicated and has fallen into disuse.

Mering discovered that an artificial renal glycosuria was produced by the administration of phlorizin. Casper and Richter made use of this discovery to determine the function of the kidney by estimating the amount of sugar excreted after the subcutaneous injection of a given quantity of phlorizin.

Various dyes have been used to determine the kidney function. Methylene-blue and indigo-carmine have been long in use, and the latter is much employed even at the present time. Delay in the appearance of the dye, diminished depth of colour, and prolongation of the time necessary to eliminate the colour from the urine indicate reduction of the excretory power of the kidney. These dyes have also been extensively used to disclose the position of the ureteral orifice by the deep blue colour which they impart to the efflux (chromocystoscopy). In 1910 Geraghty and Rowntree[11] introduced the phenolsulphone-phthalein test. This is a colour test of great accuracy, and is extensively used in America.

Accumulation of urea in the blood indicates deficient elimination by the kidneys. An estimation of the amount of blood-urea is, therefore, a test of kidney efficiency. The work of Folin and Denis, the American biochemists, so simplified the technique for accurate estimation of blood-urea that the determination soon became a routine measure in urological clinics.

For the past few years Maclean's urea-concentration test has been one of the favourites in this country. Calvert,[12] a graduate of our own medical school, has amplified this test by estimating the range of urea concentration, from the most dilute to the most concentrated, by suitable administration of fluids. Calvert's modification of Maclean's test is probably one of the best in use at the present time.

The diastatic test, the creatinin test, the chloride concentration test and many others are in general use, but time will not permit me to dwell on them.

RADIOLOGY.

The discovery of X rays by Rontgen in 1895 and the application of this discovery by Macintyre in 1896 to the diagnosis of renal calculi opened a new era in the study of urological complaints. Every year since, urology has benefited in some new way until, at the present time, it is not too much to say that radiography rivals the cystoscope in importance as a diagnostic measure. One of the first problems that confronted the urologist when shadows were first discovered in the region of the kidney, ureter, or bladder was to determine whether they were actually in the urinary tract or outside it. The opaque ureteral catheter and radiography settled the matter. Stereoscopic or antero-posterior and lateral radiograms defined accurately the position of the shadows relative to the opaque catheter and greatly facilitated the task of the surgeon. Another use of the opaque catheter is to locate foreign bodies lying in or near the urinary tract. In this way the position of bullets or fragments of shell in relation to the kidney or ureter can be accurately determined.[13]

The next great advance due to X rays was pyelography. In 1906 Voelker and von Lichtenberg[14] used collargol, which gives a shadow with X rays, to inject the pelvis of the kidney, and demonstrated its shape, size, and position. This substance was found to be unsatisfactory and various substitutes were tried, the most important of which was thorium. Since 1918, however, bromide and iodide of sodium have replaced former media, and of these iodide of sodium is most used. When a solution is introduced into the pelvis of the kidney, the ureter, or the bladder, or all three, beautiful shadows of the pelvis and calyces of the kidney, of the ureter, and of the bladder can be obtained. Alterations in shape, size and position, filling defects and diverticula can be demonstrated with the greatest clearness.

In the same way, by means of the urethroscope, the openings of the ejaculatory ducts may be localised and opaque media injected into the vesiculæ to obtain X ray evidence of their condition, and the urethra itself may be examined by filling it with the opaque medium. The diagnostic value of these examinations is daily becoming more universally recognised. Pyelography is especially valuable, and as experience accumulates the urologist becomes competent from a study of the pyelogram alone to form an opinion as to the condition of the kidney. He may thus be able to diagnose hydronephrosis, tumours, polycystic disease, tuberculosis and other affections of the kidney.

In this connexion may be mentioned a method of demonstrating the shape and size of the kidney introduced in 1921 by Carelli and Sordella and, independently, by Rosenstein. In a good X ray photograph the outline of the kidney can, of course, be seen, but if oxygen is introduced through a hollow needle into the perirenal tissues this outline is more clearly defined. The photographs thus produced are very striking and will no doubt be of service in diagnosis. Another method is to introduce the oxygen into the peritoneal cavity and take X ray photographs. The outline of the kidney after this procedure is seen much more clearly than in ordinary radiograms. The gas separates the kidney from the adjacent viscera, including the liver or spleen, and enables its shadow to be more easily recognised.

Another function of the cystoscope in diagnosis is intravesical photography. Nitze invented a camera with which he was able to take ten successive pictures of the interior of the bladder. I have experimented with a photographic cystoscope purchased in 1918 from Loewenstein of Berlin. I took a number of photographs with this instrument and obtained clear pictures of the orifices of the ureters, of the blood-vessels, and of calculi, but I could not get good definition of tumours, and inflammatory conditions could not be satisfactorily shown. During the war I intended to make use of this cystoscope, but I found a far better delineator in the person of Mr. A. K. Maxwell, the well-known artist, who was working in France under the auspices of the Medical Research Committee. He produced some of the most beautiful coloured cystoscopic pictures ever published of gunshot wounds of the bladder.[15] His drawings of gunshot wounds of the kidney, many of them coloured, were of equal merit.[16]

THE CYSTOSCOPE IN TREATMENT.

For treatment and for operative work[17] the cystoscope and the urethroscope have proved equally valuable. Nitze invented many additions to the cystoscope, including forceps, cauteries, snares, and stone crushers. He devised an instrument with which he was able to snare a polypoid tumour and cauterise the pedicle. Casper, Lewis, Buerger, Beer, McCarthy, Caulk, Young and others have added many ingenious instruments for use with the cystoscope. With these it is possible to remove foreign bodies, fragments of stone, and specimens for pathological examination. Additions have also been devised to dilate or divide the orifices of the ureters, and to perform the operation of litholapaxy under the direction of the eye. Minor operations through the cystoscope and urethroscope are of daily occurrence. By the ureteral catheter the pelvis of the kidney may be drained and irrigated, and by the urethoscope applications may be made to the utricle and, by means of a syringe and special cannulæ, the ejaculatory ducts may be catheterised and injections made, for therapeutic purposes, into the ampullæ and seminal vesicles.

THE USE OF DIATHERMY AND RADIUM IN UROLOGY.

In 1910 Beer[18] revolutionised the treatment of papilloma of the bladder by the use of the high-frequency current applied through the cystoscope. With the improved apparatus now at our disposal even multiple papillomata can be efficiently treated while the patient walks about and carries on his ordinary vocation. The advantages of this highly important discovery lie not only in the comfort and safety with which the treatment can be carried out, but also in the fact that a recurrence can be dealt with at the earliest possible moment without damage to the urethra, the abdominal wall, or any other part. The current is applied through a platinum-tipped ureteral catheter, and it is one of the thrills of surgery to see the leaves of the papilloma crumple up like singed feathers when the charged electrode is brought into contact with them.

For malignant tumours of the bladder, treatment by diathermy is only rarely applicable, but modern surgery has so progressed that it is possible to remove half, three-quarters, or even more of the bladder, together with the infected lymph channels and glands, the remaining portion expanding in a few months to accommodate itself to the altered conditions. Other uses of diathermy are to enlarge the ureteric orifice to allow of the passage of a calculus, and to treat resistant ulcers in the bladder, such as those due to tuberculosis.

The discovery of radium in 1898 by Professor and Madame Curie opened up another fruitful field in the therapeutics of urology, but it was not, I think, until 1911[19] that results began to be published. Since that time many ingenious instruments have been devised by means of which, through the cystoscope, radium in the form of emanation seeds or element in small needles can be placed in any part of the bladder for the cure of simple papillomata or malignant growth. At the Johns Hopkins Hospital, in which the first practical application of this method was made in 1914, many hundreds of cases have been treated, with results which show that radium applied through the cystoscope is one of the most important and successful methods at our disposal for dealing with tumours of the bladder.

NEPHROTOMY AND PROSTATECTOMY.

The treatment of renal calculi by modern methods is another of the triumphs of surgery. Sir Benjamin Brodie, writing in 1842,[20] says: "Some of the old surgeons have spoken of an operation for the extraction of calculi from the kidney. The proposal is absurd and dangerous." To-day the operation is almost without mortality if done before the calculi are allowed to block the ureter or to grow to such dimensions that extensive nephrotomies are required to release them.

Prostatectomy has proved a priceless boon to a large section of men who have passed the prime of life. Before the days of prostatectomy the condition of some of these patients was pitiable in the extreme, and many of them were willing to submit to any procedure, however drastic, that held out any prospect of relief. Partial prostatectomy, by the suprapubic route, was performed by surgeons long before complete enucleation was thought of. Amussat in 1827, Dittel in 1885, Belfield in 1886, and McGill in 1888 paved the way for the modern operation, which appears to have been first performed by Eugene Fuller of New York in 1894. P. J. Freyer undoubtedly first launched the operation in England in 1901 and by his strong personality and strenuous advocacy, combined with his own remarkably low rate of mortality, established it on a sound practical basis. Freyer must, therefore, be considered a pioneer in the operative treatment of prostatic hypertrophy.

Perineal prostatectomy was similarly foreshadowed by attempts at removal of portions of the gland at different times, commencing with Covillard who, in 1639, appears to have torn away a portion of the prostate after perineal lithotomy. Sir William Ferguson in 1840, Billroth in 1867, and others followed but, according to Young,[21] Goodfellow, who performed the operation in 1891, deserves the credit of being the first to make a success of it.

The French school, represented by Proust and Albarran, exposed the prostate in the perineum and excised it piecemeal, but the operation of conservative perineal prostatectomy was finally developed in 1903 by Young of Baltimore, who still remains its most brilliant exponent. Young has also invented a cautery punch for cases in which the obstruction is due to a median prostatic bar. By this instrument the obstruction can be removed without disturbing the lateral lobes of the gland. The operation is an endo-urethral one, and has been carried out in a large series of cases with remarkably good results.

Finally, mention must be made of the endo-urethral method developed by Georges Luys of Paris in 1911.[22] His method, "forage de la prostate," consists in removing through the urethroscope, by means of the galvano-cautery or by diathermy, those portions of the prostate which obstruct the outflow of urine. If the results claimed by Luys are obtained by other surgeons, this method of treatment should become a useful addition to the resources of the urologist.

The mortality records of Freyer, Young, Thomson-Walker and other well-known urologists are so good that it would seem almost presumptuous to suggest any improvement in technique, but I have felt for some time that the comfort of the patient might be increased and the incidence of sepsis diminished by a combination of the suprapubic and the perineal operative routes: removal of the prostate by the suprapubic and drainage by the perineal. By this means a continuous stream of fluid can be maintained through the bladder and the patient kept dry during his convalescence. An account of this method, which is at present on its trial at this medical school, has recently been published.[23]

A great medical school is not built up in a day, nor is it given to any one individual to be an outstanding factor in its development, but there are certain men who, by their ability, their foresight, their devotion, their industry, their unselfishness, and their personality, make a lasting impression on its progress. We recall with pride the names of such men as Thomas Andrews, Alexander Gordon, Peter Redfern, James Cuming, W. A. McKeown, Johnston Symington and others, who played no small part in building up the reputation of the Belfast medical school. No one will deny to Robert Campbell the right to stand as a peer among these great men who, in spite of many obstacles, materially advanced our standing as a centre of medical education. With men of the stamp of Robert Campbell to represent us in the world of medical science, the future of our medical school is secure.

OBSERVATIONS ON THE
BRUIT D'AIRAIN (COIN SOUND, BELL SOUND).

BY A. I. GRANVILLE McLAUGHLIN, M.B. SYD.,
CHIEF ASSISTANT, TUBERCULOSIS DEPARTMENT, ST. THOMAS'S HOSPITAL;

AND

A. J. DIX-PERKIN, M.B. CAMB.,
RESIDENT MEDICAL OFFICER, BRITISH HOSPITAL, PORT SAID, EGYPT.

THE *bruit d'airain*, or, as it is commonly called in this country, the coin sound, is the most distinctive and the least understood of the pulmonary acoustic phenomena. It can be heard only when an air-containing cavity (a pneumothorax, a pulmonary cavity, and very rarely a pneumo-pericardium) is present in the thorax. The sign is not constantly obtained in pneumothorax, even when complete collapse of the lung exists. That is to say, the presence of the bruit d'airain is diagnostic of an air-containing cavity, but conversely the absence of the sign does not exclude the presence of such cavity. It was this fact which led to the study of the present series of cases in order to determine if possible the physical or pathological factors governing the incidence of the sign.

It will be convenient at the outset to state or re-state the following facts concerning the bruit d'airain, about which fairly widespread misconceptions have arisen since its original description.

1. The bruit d'airain is one of a group of metallic *phenomena* which *may* be heard in the thorax under varying conditions. The other members of the group are: (*a*) amphoric breath sounds; (*b*) metallic vocal resonance, either of the whispered or spoken voice; (*c*) metallic or tinkling crepitations; and (*d*) the (Hippocratic) succussion splash. All these signs are associated with the presence of an air cavity or cavities in the chest. For the production of tinkling crepitations and the succussion splash, fluid or secretion is a necessary additional factor.

2. The bruit d'airain is a clear ringing musical note exactly like that made by striking a sharp blow on a brass vessel (French: *airain* = brass), and it is elicited by listening over the anterior or posterior wall of the chest while an assistant percusses or taps two coins together on the same or opposite wall. Although it is more convenient to use two coins it must be emphasised that the note produced by two pieces of wood, or by simple digital precussion, is of exactly the same musical pitch and quality as that produced by percussion with coins, whether gold, silver, or copper.

3. Over some pneumothorax cavities a dull, wooden, non-musical note is sometimes heard. To this sound the term *bruit de bois* has been given by French clinicians.

4. In some cases of hydropneumothorax the bruit d'airain may be obtained over the air space down to the level of the fluid, but over the fluid itself a higher pitched, fainter, silvery note may occasionally be heard. To this is given the name of the *signe de Pitres* or the *signe de sou*, described by Sieur[1] in a Thèse de Paris in 1883.

Historical.

Laënnec,[2] in his "Traité de Médiate Auscultate," gave an excellent description of the physical signs of pneumothorax with the exception of the bruit d'airain. This sign was first described in April, *1857, in an anonymous paper*[3] entitled "Pneumothorax—nouveau signe pathognomique de cette affection." The writer reported a case of pneumothorax and said that a sign was present which had been discovered and reported several years before by A. Trousseau. It was obtained by auscultatory percussion, and the resulting sound was so intense as to hurt the ear, resembling the note given out by a brass vessel when struck sharply. He further stated that the sound was pathognomonic of air in the pleural cavity. Boursot,[4] in 1888, dealt with the bruit d'airain, and concluded that one of the most important signs of pneumothorax is the sound elicited by the combined percussion and auscultation of the anterior region of the chest. Harris,[5] in St. Bartholomew's Hospital Reports of 1887, reports five cases of spontaneous pneumothorax, and makes the following note about the bell sound:—

> "In conclusion I may remark that in my experience the bell sound is generally absent *at first*, and that it is then generally heard over wide areas. Later on the sound becomes more localised in extent and can only be heard on very careful and minute percussion with coins over the whole chest. Not infrequently, however, the bell sound may be replaced as the case progresses by some less clear sound, which is exactly like that made by a hammer striking an anvil. I do not know whether this sound has previously received such a name but I always call it the anvil sound."

In 1890 Chauffard[6] reported a case of left-sided pneumothorax following a violent movement of the left arm. The patient was admitted to hospital on the fifth day after the onset. No fluid was present. The whole chest was tympanitic with the absence of the respiratory murmur and vocal fremitus. No metallic phenomena, no tinkling, and no succussion splash were present, *but a splendid bell sound was obtained*. Hoover,[7] in 1898, considered that the coin sound depended, not on the tension of the gas, but on the tension of the walls of the cavity. In 1895 Osler[8] reported a case of chronic tuberculosis with a large cavity in the right upper lobe, with thickened, adherent pleura. In this patient during life the coin sound was heard with great intensity. Until this time the general idea was that the sign was distinctive of pneumothorax.

Emerson,[9] in his masterly and exhaustive monograph on pneumothorax in 1903, reports 48 cases, and in his section on the coin sound remarked that "it should be borne in mind that for the sound of the tap of the coins to be very clearly transmitted does not make the sign positive. The amphoric quality furnished by a resonant cavity is necessary." Unfortunately, in his analysis of cases he does not give his opinion as to why the coin sound was heard in some cases and not in others. Owing, however, to the full notes made on each case, we have been able to determine the type of case in which the coin sound was present or absent in his series.

Our analysis shows that 28 of these cases were investigated for the presence or absence of the bruit d'airain. The sign was present in 22 cases, suggestive in 2, and absent in 5. Fifteen out of the 22 positive cases were examples of pyopneumothorax, 5 of them were hydropneumothoraces and 2 were cases of pneumothorax. Of these two cases one was a case of pneumothorax of 12 years' standing without lung expansion. The other was a case of pure pneumothorax in which the bruit d'airain was heard. Of the cases not giving the sign, one was a case of pure pneumothorax and four were pyopneumothoraces before aspiration. No note was made on the bruit d'airain after aspiration.

F. T. Lord,[10] in Osler and McCrae's "Modern Medicine," remarks that the coin sound like amphoric breathing is probably due to the peculiar resonating qualities of the pneumothorax cavity. Fishberg[11] is of the opinion that the coin sound is due to the presence of fluid in the pneumothorax cavity.

Pratt and Bushnell[12] state that "the cavity of the pneumothorax acting as a resonator reinforces the metallic sounds as overtones of its fundamental note, and since the thoracic wall vibrates as a part of the resonator, the sound is heard by the ear, as it were, at the very place of its production." It is clear that this theory is based on the erroneous assumption that coins are necessary for the production of the coin sound. The remarks of Powell and Hartley[13] seem to have been influenced by the same idea.

The Italian physicians have paid considerable attention to the acoustic phenomena of pneumothorax cavity. Morelli[14] and Moron[15] stated that the bruit d'airain is more marked when the intrapleural tension is high. Cesare Minerbi[16] in a series of studies during 1913–14 pointed out that the necessary conditions for the production of the bruit d'airain are: (1) the cavity must be of sufficient volume: (2) the mediastinal and thoracic walls of the cavity must be sufficiently tense; and (3) that the shape of the cavity must be more or less regular.

In a further interesting series of studies, Minerbi, Mongoni, and Benassi[17] showed that in cases of complete therapeutic pneumothorax where the bruit d'airain was present two distinct tones were invariably found,* one a higher pitched tone corresponding to the extreme points of the diameter extending from the interscapular vertebral space to the base of the mediastinum, and a lower tone corresponding to a line joining the apex of the hemithorax to the costal margin—i.e., a high note corresponding to the short transverse diameter of the cavity, and a lower note corresponding to the longer vertical diameter. They also said that these two sounds were only obtained when the intrapleural pressure reached a level between zero and +1 of the water manometer—i.e., a slight positive pressure. Another observation which they made was that in the first 24 hours after re-establishing the pressure in an already complete pneumothorax the *bruit d'airain cannot be obtained, even if a positive* intrapleural pressure exists.

In a report by one of us (McL)[18] of a case of simultaneous bilateral artificial pneumothorax in which it was possible to study in the same patient the bruit d'airain in two pneumothorax cavities, in only one of which a pleural effusion had occurred, the statement was made that the bruit d'airain or coin sound is elicited in its most marked and characteristic form when the pleura has been thickened or sclerosed by the onset and subsequent absorption of a pleural effusion, either serous or purulent; further, that the main condition for its production, apart from the presence of an air-containing cavity in the thorax, was the hardening and increased elasticity of the wall of the cavity and not the tension in the cavity or the presence of a certain amount of fluid, as other observers had stated.

Analysis of Cases.

The cases examined in this series were 50 in number, of which 26 were males and 24 females. Artificial pneumothorax was induced on the right side in 28 cases and on the left in 24. In two cases a pneumothorax was *induced simultaneously on both sides.*

These cases were examined over a period of two years for the presence or absence of the bruit d'airain in relation to varying conditions, such as the development of pleural effusion, the condition of the walls of the cavity, intrapleural tension, selective collapse of the lung, hydropneumothorax, mediastinal displacement, and ballooning of the pleura. The sign has been investigated in all stages of lung collapse ranging from just after induction, when the air space in the pleural cavity is small, to the period of complete collapse of the lung. Each case was examined on many occasions for the presence or absence of the sign, and it should be noted that at certain stages and under varying conditions in the same cases the bruit d'airain was present at times and absent on other occasions. But in general of the 50 cases, two of which had simultaneous bilateral pneumothorax, the bruit d'airain was present at one stage or another over 28 pneumothorax cavities and in the other 24 it was absent in all stages.

On considering the 28 cases in which the bruit d'airain was heard, it was found that 23 developed pleural effusion during the course of the artificial pneumothorax. Of the remaining five, Case 1 had a previous history of a fibrinous pleurisy and showed signs of a rigid pleura (estimated by the resistance to the pneumothorax needle and by rapid increase of intrapleural pressure during a refill) with bronchiectasis at the left base. Case 7 developed an acute fibrinous pleurisy during the course of pneumothorax treatment. Case 15 showed clinical and radiological evidence of a mediastinal bulge. At this time the bruit d'airain was present but was not heard when the mediastinum returned to the normal position, although the lung was still collapsed. Case 27 did not have a pleural effusion during the course of artificial pneumothorax. A faint bruit d'airain was heard during a period of ballooning of the pleura. This patient also had dense consolidation of the underlying lung. She went to a sanatorium and no further notes are available on the incidence of the bruit d'airain in her case. Case 21 after a refill developed pleural pain which may reasonably be believed to have been acute fibrinous pleurisy. Following this a beautiful bruit d'airain was obtained all over the cavity and was still present two months later.

It is a remarkable fact that in the 24 cases in which no bruit d'airain was ever heard there was no incidence of pleural effusion or fibrinous pleurisy, either before or during the course of treatment. In the majority of these the lung showed good collapse, and in some cases complete collapse.

Pre-effusion Bruit d'Airain.

In four of the series the development of the bruit d'airain in cases where it had not been heard before led to investigation for signs of pleural effusion. In all four cases an effusion subsequently developed.

Case 12.—The bruit d'airain was present for the first time on Jan. 19th, 1928, after the pneumothorax had been established for eight months. There was no clinical evidence of pleural effusion. On Feb. 23rd fluid was found up to the level of the eighth dorsal spine. On referring to the notes of the intrapleural pressures, we find that on Dec. 19th, 1927, the pressure before a refill was −6 ±0. 525 c.cm. of air were injected and the final pressure was ±0 +6. On Jan. 19th, 1928, the day on which the bruit d'airain was first heard, the initial pressure was −2 +5. 800 c.cm. of air were injected, making the final pressure +8 +16. The sudden increase in intrapleural pressure when only 300 c.cm.

---

* In an annotation in The Lancet (1927, ii., 981) it was stated that in all their cases of complete pneumothorax the bruit d'airain was found. On reading the monograph we find that this is not so. Only those cases in which the bruit d'airain was present were selected for experiment.

of air were injected seems to be strong evidence that the pleural membrane was hardened and more rigid than normal.

CASES 18, 31, 44 presented the same features as Case 12.

As an explanation of this pre-effusion bruit d'airain we would suggest that the inflamed pleura is in a hyperæmic and turgid state making the walls of the pneumothorax cavity harder and more rigid. This point is illustrated above in the note on intrapleural pressures in Case 12. It would seem, therefore, that the most favourable factor necessary for the production of the bruit d'airain (as we hope to show later) is present in these cases. The shape and volume of the cavity, the actual presence of the fluid, or increased intrapleural tension do not apparently influence the incidence of the sign. It will be noted, especially in Case 12, that the bruit was present (1) when the intrapleural tension was negative (before the refill); and (2) before pleural effusion had occurred.

Post-effusion Bruit d'Airain.

Repeated examinations of the cases which developed an effusion into the pneumothorax showed that in general the bruit d'airain became more intense as the effusion absorbed and as the pleural membrane became drier and more rigid. This was the most common finding in the majority of cases. In a few, of which Case 2 is an example, the fluid was absorbed fairly rapidly without aspiration. In these cases it was found that the bruit d'airain reached its maximum intensity about four months after the onset of the effusion.

CASE 2.—A girl, aged 20, with a left-sided pneumothorax induced on Oct. 25th, 1926, developed an effusion into the pneumothorax cavity on May 20th, 1927. The bruit d'airain was heard in its maximum intensity on or about Sept. 19th, 1927, when the pneumothorax cavity was dry, and the pleura on puncture with the needle was found to be tense and resistant.

In many cases no bruit d'airain was to be heard until the onset of effusion. Four cases illustrating this point are quoted above. When once the effusion was established the bruit d'airain disappeared, only to reappear perhaps faintly as the effusion cleared, but finally as the pleura became rigid and dry the note became more musical and was heard over a larger area.

CASE 3 was that of a man aged 47. Artificial pneumothorax was induced on the right side on Sept. 9th, 1926. Pneumothorax was well established in one month with fairly complete collapse. A small adhesion was present at the extreme apex. On Jan. 18th, 1927 (three months after induction), a radiogram showed that the apex remained collapsed while the lower lobe had almost completely expanded (illustrating the doctrine of selective collapse). One week later he became ill, and developed an aspiration *broncho-pneumonia in the right lower lobe. Until April 8th,* 1927, no bruit d'airain had been elicited over the pneumothorax cavity. On this date, however, a slight bruit d'airain was heard at the right base. No succussion splash or other signs of effusion could be detected at this time. On May 10th, 1927, the slight bruit d'airain having persisted, a small effusion was discovered at the right base. The effusion did not increase appreciably in amount for some months. Sometimes it appeared that the fluid had been absorbed but it began to reaccumulate in somewhat larger quantities until on April 17th, 1928, one and a half pints of fluid were aspirated and replaced by air. It was noted during the whole of this time of intermittent effusion that the bruit d'airain began to increase gradually in intensity until on May 16th, 1928, a perfect bruit d'airain was heard all over the cavity. At the time of writing a small effusion still exists and an excellent bruit d'airain is heard down to the level of the effusion. The question of the relationship between the incidence of the bruit d'airain and the intrapleural pressures in this case will be discussed later.

Bruit d'Airain in Bilateral Pneumothorax.

Case 20, which has already been reported in THE LANCET,[18] was one in which a girl, aged 17, had simultaneous bilateral pneumothorax induced. The case is of value in relation to the bruit d'airain on account of the fact that in the same patient two pneumothorax cavities were present, in only one of which pleural effusion occurred. The left pneumothorax cavity remained dry throughout the whole period of collapse. On the right side an effusion developed early. The fluid was aspirated and replaced with air three weeks later. Repeated examinations showed that the bruit d'airain developed on the right side two months after the aspiration and became more intense and musical as the pleura became drier and more rigid. The bruit d'airain persisted until the lung was allowed to re-expand one year later. It was present until the cavity became very small—i.e., it could be heard over a partial pneumothorax. On the left side, although the amount of collapse was equal to that on the right side and was more regular, the bruit d'airain was never heard.

Case 40, a man aged 23, in whom bilateral pneumothorax was present, showed the same features as Case 20.

Relationship between Intrapleural Tension and the Incidence of the Bruit d'Airain.

Most observers attribute the fact of the presence or absence of the bruit d'airain to either a negative or a positive intrapleural tension. Widal[19] seems to be in a position of splendid isolation when he stated that the sign was absent when the tension was high and present when the tension diminished. Béclère[20] in 1897 stated that the bruit d'airain was accentuated when the intrapleural tension is increased. Bendove[21] in 1926 found that the bruit d'airain was present in all cases of pneumothorax, whether open or closed, in which the pressure was at atmospheric or above, regardless of the size of the pneumothorax cavity. Although radiograms and histories of illustrative cases indicate that the pleura was thickened in those patients in whom the bruit d'airain was found, Bendove does not mention this as a factor in the production of the sign.

Reference to this series of cases shows that if certain factors are favourable the bruit d'airain is found, whether the intrapleural tension is negative or positive. In many cases before a refill a beautiful bruit d'airain was elicited and on insertion of the pneumothorax needle the intrapleural pressure was found to be negative, e.g., −8 −2. On raising the pressure by injection of air to a positive figure, little alteration was found in the intensity or character of the bruit d'airain. This feature was so constant that the theories stating that a positive intrapleural pressure must be present before a bruit d'airain can be elicited can be dismissed as erroneous.

Reference to the table will illustrate this point.

Case.	Intrapleural tension before fill.	Amount of refill.	Intrapleural tension after fill.	Presence of bruit d'airain.
		c.cm.		
3	−11 −3	400	+10 +16	Present before and not altered by refill.
	− 9 −0	250	+ 5 +11	
4	− 6 +1	375	+ 4 +12	Present before and after refill.
	−10 −3	600	− 3 − 4	Present before—more intense at base after refill.
7	− 8 +1	600	− 4 + 6	Faint before—more marked after.
	− 8 ±0	200	+ 8 +10	Present before—more intense after.
8	−14 +2	200	+10 +20	Present all over before and only over upper zone after.
	− 9 −1	550	− 3 + 5	
31	− 5 −1	300	0 + 3	Present before—duller after fill.
	− 5 +1	350	+ 1 + 7	Present all over before—duller and practically absent after fill.
38	−11 −1	750	− 1 + 6	Present before and after fill.
40	−21 −7	500	+ 1 + 9	Present before and after refill.
42	−10 −5	600	− 4 + 4	Ditto.
44	−13 −5	300	− 8 + 1	Ditto.

Cases 2, 5, 6, 12, 17, 18, 42 illustrated similar phenomena fully represented by Case 3.

It will be seen that in many cases a bruit d'airain was heard when the intrapleural pressure was negative (see Cases 38–44). In some instances the bruit d'airain was heard better after the refill, as in Case 4. It will be noticed, however, that even the final intrapleural pressure was negative. In Case 7 the bruit d'airain was heard better after the fill when the intrapleural pressure became positive. These cases are in the minority and the improvement in the bruit d'airain can be ascribed to other factors such as the increase in the volume of the pneumothorax cavity.

Relationship of Bruit d'Airain to the Size and Volume of the Pneumothorax Cavity.

After the induction of an artificial pneumothorax the shape alters and the volume of the cavity gradually increases until, if no adhesions are present, complete collapse is obtained. If the pleural membrane retains its normal thickness and resilience, and neither mediastinal displacement nor ballooning of the pleura occurs, no bruit d'airain is obtained. This is well shown in Cases 22 and 24, in which collapse was induced in a normal lung for the purpose of transpleural operation on a carcinoma of the œsophagus.

Variations in the shape and volume of the cavity depend on several factors:—

1. *Presence of pleural adhesions.*—A firm adhesion in any situation will prevent the uniform collapse of the lung and hence the production of a regular cavity. The situations of adhesions may be: (*a*) apical, (*b*) mid-zonal, (*c*) basal. For instance, in this series of cases 15 had a free pleura with no adhesions, 17 had apical adhesions, 3 had mid-zonal, 3 had basal, and 2 cases showed both apical and basal adhesions. On the remaining six cases no notes as to the presence of adhesions were made. In some instances the adhesions stretched into long ribbon-like structures and did not prevent the even collapse of the lung. In other cases broad, sheet-like adhesions prevented even collapse of the lung and thus altered the shape of the pneumothorax cavity. It is in these cases that breath sounds are well heard locally over the site of the adhesions. Presence of adhesions per se did not appear to have any appreciable influence on the bruit d'airain, except in so far as their presence rendered the patient more liable to the onset of pleural inflammation and subsequent effusion. Apical or basal adhesions, while diminishing slightly the size of the cavity, did not prevent the formation of a fairly regular pneumothorax. Cases in which adhesions did play a definite part in the disappearance of the bruit d'airain were those in which an obliterative pleurisy developed.

2. *Selective collapse.*—The pneumothorax cavity is sometimes altered in shape by the fact that the diseased areas of lung tissue tend to remain collapsed whilst the healthy areas re-expand. In this series of cases where there was radiological evidence of selective collapse no bruit d'airain was heard. In cases which had a pleural effusion this phenomenon of selective collapse was never seen after the effusion had cleared. The explanation seems to be that the whole pleura is thickened as a result of past inflammation sufficient to prevent the re-expansion of the underlying healthy lung. In those cases which never had an effusion, the pleura, being normally elastic, did not prevent re-expansion of the lung. The absence of the bruit d'airain in these cases of selective collapse might be due to irregularity of the pneumothorax cavity. Further reference, however, to these cases shows that when the lung was evenly collapsed by a further injection of air, the bruit d'airain was still absent. This point was well illustrated in Cases 3 and 45. The explanation of the absence of the bruit d'airain seems to lie rather in the fact that the pleura was not thickened and the shape of the cavity played little or no part.

3. *Hydropneumothorax.*—The presence of an effusion into an artificial pneumothorax cavity definitely alters its shape and lessens the volume. If the cavity is completely or almost filled with fluid the bruit d'airain is not found owing to obliteration of the air cavity. If the fluid occupies about a half of the pneumothorax cavity a good bruit d'airain is usually heard above the level of the fluid. In a few cases the signe de Pitres was obtained over the fluid. This, however, was not constantly observed. Biermer's[22] "change of sound" was found in those cases in which there was a moderate effusion and a fairly complete pneumothorax. The sign consists in an alteration of the pitch of the bruit d'airain when the patient is examined both in the horizontal and upright positions.

4. *Mediastinal displacement and ballooning of the pleura.*—These conditions are sometimes produced during the course of establishment of an artificial pneumothorax by the too rapid compression of the lung. A patient with a lax mediastinum is especially liable to these complications. In displacement, the whole of the mediastinum is displaced to the opposite side and in the other case the pleural reflection is ballooned across the mediastinum without there being much displacement of the mediastinum itself. In both conditions the shape and volume of the pneumothorax cavity is definitely altered. A faint bruit d'airain or a bruit de bois is occasionally heard over the base of the pneumothorax in cases with mediastinal displacement. The sign is obtained even in cases with no evidence of pleural thickening. Again, when there is ballooning of the pleura with either a negative or positive intrapleural pressure a faint bruit d'airain or sometimes a bruit de bois may be elicited over the pleural hernia, definitely outlining the shape of the bulge.

CASE 16 was an instance of right-sided pneumothorax in which there was a complete pneumothorax without adhesions or thickening of the pleura. During a period when there was over-displacement of the mediastinum a faint bruit d'airain was heard over the right base. When, however, the mediastinum returned to its normal position, the lung still remaining collapsed, the faint bruit d'airain disappeared.

CASE 27 was an example of partial pneumothorax in which there was ballooning of the pleura but no mediastinal displacement. Over the pleural hernia a faint bruit d'airain was found outlining the curved shape of the distended pleural reflection. When this distension was allowed to contract the bruit d'airain disappeared and was not obtained again up to the time the patient left for sanatorium treatment.

Relationship between Bruit d'Airain and the State of the Cavity Walls.

Thickening and rigidity of the cavity walls most commonly follows purulent or serous effusion into the cavity. Less commonly it results from an acute fibrinous pleurisy, and also from involvement of the pleura over a diseased area in the lung. Consolidation of the lung itself in some cases may cause rigidity of the walls. Temporary rigidity may be caused by an acute inflammatory process in the pleura occurring before the onset of an effusion. In all our cases in which rigidity of the cavity wall was present, bruit d'airain, either localised or generalised, was heard. This constitutes the main point of our thesis.

Relationship between the Bruit d'Airain and the Other Metallic Phenomena.

In some of our cases the metallic phenomena (bruit d'airain, amphoric breath sounds, metallic vocal resonance, tinkling crepitations, and the succussion splash) were heard at one time or another. Sometimes all five signs would be heard in the one case, as, for example, in Case 3, in which there was a consolidated, partially collapsed lung associated with hydropneumothorax. In such a case it was noticed that all the signs possessed the same note in the musical scale, and that the quality or timbre of each note was identical.

In a dry pneumothorax cavity, with the lung completely collapsed and the pleura hardened, the bruit d'airain was the only metallic phenomenon to be heard. If a collection of fluid was present in the pneumothorax cavity, the succussion splash as well as the bruit d'airain was elicited. Amphoric breath sounds were heard: (1) when the lung was partially collapsed with an area of consolidation around one of the bronchi; (2) when an uncollapsed pulmonary cavity was present; and (3) when a broncho-pleural fistula had formed. In no case were amphoric breath sounds heard in the absence of the bruit d'airain. Further, if the amphoric breath sounds were faint and distant or loud and echoing the bruit d'airain possessed similar characteristics. When in addition secretion was present in the lung tinkling crepitations were heard.

In regard to the significance of amphoric breath sounds over a pneumothorax cavity, we are unable to agree with Bendove who regards them as indicating a broncho-pleural fistula in every case. We are convinced that in certain cases amphoric breath sounds are those that would normally be heard as bronchial breath sounds in a consolidated lung or over a pulmonary *cavity, with a musical quality imparted* to them by an adjacent air-cavity. Again, although tinkling crepitations may in some instances be due to air bubbling up through fluid from a submerged fistula, as some observers state, we are inclined to agree with James,[13] Gerhardt,[14] and Kinghorn,[15] that they are in many cases ordinary crepitations modified by the resonating musical qualities of the adjacent pneumothorax cavity. Tinkling crepitations may also be produced in a pulmonary cavity when its volume and the rigidity of its walls are favourable.

The presence of tinkling crepitations and amphoric breath sounds over a pneumothorax cavity in our experience indicates that the collapse of the lung is incomplete. The bruit d'airain may be heard whether the collapse is complete or partial.

Localised Bruit d'Airain.

In many cases of partial collapse the bruit d'airain was heard only over the base of the cavity, occasionally over the upper zone, and in rare cases over the mid-zone, depending primarily on the situation of the air space. In one case of basal bronchiectasis with complete collapse the bruit d'airain was heard only over the base, presumably because the two layers of the pleura and the lung were thickened only in the lower region. As stated elsewhere, a faint bruit d'airain was also heard at the base in those cases where mediastinal displacement was present.

Discussion.

The term "coin sound" as a synonym for the "bruit d'airain" is misleading and should not be used. It has given rise to the misconception that the clear ringing note obtained is due to amplification of the metallic sounds. "Bell sound" is a better term because its use does not infer that the use of coins is necessary in the production of the sign. It seems best, however, to keep to the original term "bruit d'airain," which was originally described as a phenomenon to be elicited by auscultatory percussion.

The sign, whatever method is used to set up vibrations in the pneumothorax cavity, is a musical note of constant pitch and quality. Each cavity has its proper note—that is to say, that the bruit d'airain is inherent in the cavity and not in the method used to elicit the sign. A further interesting fact is that in some cases all or some of the following signs may be heard—succussion splash, tinkling crepitations, amphoric breath sounds, and the bruit d'airain—and in each case the fundamental musical note is the same *for all these signs.* The presence or absence of the bruit d'airain depends on many factors which are as yet imperfectly understood. But as a result of the prolonged study of these cases we have been able to establish factors which play an important part. The most important appears to us to be: (1) *The condition of the wall of the cavity*—namely, that the wall should be sclerosed and rigid, a state of affairs which most *commonly results from the onset of a pleural effusion* into the pneumothorax cavity. If the effusion is absorbed or is replaced by air, the drying and hardening of the pleura, accompanied by a beautiful bruit d'airain, reaches its maximum about four months after the onset of the effusion. From this time the sign persists in similar intensity until the lung is allowed to expand. The hardening of the walls of the cavity can also be ascribed, although less frequently, to pleurisy occurring before the induction of the pneumothorax, to consolidation of the underlying lung, and to acute fibrinous pleurisy occurring during the course of the pneumothorax. (2) *The size or volume of the cavity* is of moderate although not of paramount importance. The bruit d'airain, if present at all, is heard over an area of the chest wall usually in proportion to the amount of collapse. It was noted in a fair number of our cases that the sign was present over the base, probably owing to the fact that the volume of the pneumothorax was greater in that situation. But if the pleural membrane is hardened the bruit d'airain can be heard even over a small cavity. Conversely, *if the pleura is not hardened, and the volume of the* pneumothorax large, the bruit d'airain is in the majority of cases not elicited. (3) *The shape of the cavity* appeared to play only a minor rôle in the production of the bruit d'airain. (4) *In mediastinal displacement and ballooning of the pleura* a faint bruit d'airain may be heard. The explanation of this, although not quite clear, seems to lie in the combination of three factors—viz., the shape and volume of the cavity and tension on the cavity walls. (5) *Intrapleural tension* is not a factor which determines the absence or presence of the bruit d'airain, but with a positive pressure the sign is usually a little more intense. (6) In *hydropneumothorax* the bruit d'airain is heard when the effusion is small or moderate. In our opinion this is not due to the presence of fluid *per se*, but to the accompanying hardening of the walls of the cavity.

We *have not been able to confirm the observation* of Minerbi, Mongini, and Benassi that the bruit d'airain tends to disappear in long-standing cases of pneumothorax. If the pneumothorax is maintained, the bruit d'airain persists, and sometimes in greater intensity as time goes on. Nor have we confirmed their remark that the sign disappears in the 24 hours following a refill. In practically all our cases when the sign was present before the refill it was heard afterwards, sometimes more intense and usually over a wider area. But we agree with their interesting observation that in nearly complete and complete pneumothorax two distinct and separate notes are heard—the lower pitched note corresponding to the long axis of the cavity, and that of higher pitch to the short axis. In our experience the presence of the higher note was not governed by the fact that the *intrapleural tension was just above zero. In our* cases it was heard whether the tension was positive or negative.

Value of the Bruit d'Airain in Diagnosis.

The first important point to be observed is that failure to elicit the bruit d'airain does not mean that a pneumothorax is not present. Secondly, when the sign is found over the thorax, it gives an indication of the presence of *an air-containing cavity with tense and rigid walls.*

When the mediastinum is displaced the bruit d'airain gives an indication of the amount of displacement. For instance, in excessive displacement the sign can be found extending across the spinal column to the side of the uncollapsed lung. In ballooning of the pleura, the shape and extent of the bulge can be accurately marked out by means of the bruit d'airain. When a hydro- or pyo-pneumothorax is present, the sign is heard down to the level of the fluid, and in this way the amount and level of the fluid can be fairly accurately estimated. In this connexion the bruit d'airain is of much more value than the percussion note, especially in those cases (usually pyopneumothoraces) where a tympanitic or skodaic note is found over the effusion itself.

We wish to acknowledge our indebtedness to Dr. G. T. Hebert, who kindly allowed us to study and include his cases in our series.

ASSAM'S MALARIA PROBLEMS

AND THEIR SOLUTION.

BY G. C. RAMSAY, O.B.E., M.D. EDIN., D.T.M. & H.,
SENIOR MEDICAL OFFICER, LABAC CENTRAL HOSPITAL, CACHAR, ASSAM.

IN a recent paper[1] I stressed the importance of *Anopheles minimus* as the main vector of Assam malaria and also the importance of controlling its breeding areas during the malaria season—i.e., in its monsoon or summer resorts. I said :—

> "The factor which determines the migration of *Anopheles minimus* from a winter to a summer resort is, of course, rainfall. *A. minimus* migrates to lay her eggs in breeding areas at higher and safer levels, free from the dangers of flooding and flushing. The usual monsoon breeding areas of *Anopheles minimus* are slow-running grassy-edged drains, streamlets and streams, sometimes certain types of seepages, and certain types of tanks. It is interesting to note that in its winter resorts *A. minimus* rarely migrates to low-lying drains. These areas are carefully avoided, like some seepages and swamps, owing to contamination with the products of iron-oxide bacteria. Likewise, certain types of stagnant water contaminated with certain types of algæ appear to be factors in restricting the winter breeding areas mainly to the clear water at the grassy edges of slow-running rivers and perennial streams."

As a result of a further study of the subject it is apparent that two of the factors I mentioned as controlling the breeding habits of *A. minimus*—viz., flooding and flushing—should more correctly be described as water contamination and high velocity of current. It has long been known that certain species of anopheline mosquitoes breed exclusively in clear uncontaminated water. A careful further study of anopheline breeding areas on the terrain under my supervision, which has been regularly surveyed during approximately the past three and a half years, has shown that the breeding habits of *A. minimus* are entirely regulated by the availability of clear, uncontaminated, slow-running, or stagnant water, completely or partially exposed to sunlight. The small pockets at the grassy edges of slow-running streams, streamlets and drains, the edges of grassy tanks, kutcha wells, pools, and borrow-pits; also grassy swamps and seepages if the water is uncontaminated and completely or partially exposed to sunlight, are therefore all potential breeding areas. This I have recently proved repeatedly and the classification of *A. minimus* as essentially a stream-breeder would lead to many dangerous breeding areas being left uncontrolled. The prevalence of *A. minimus* in slow-running grassy streams and drains is doubtless due to the mechanical filtering and clarifying effect on the water of vegetation (grass and weeds) growing on the banks and sometimes in the bed of drains and streams, in addition to its action in retarding the rate of flow.

Uneven Rainfall.

The solution of Assam's malaria problem is, however, mainly dependent on solving the effects of an uneven distribution of rainfall on the habits of *A. minimus*, the main natural carrier of malaria in Assam. In countries where the rainfall is more or less evenly distributed throughout the year it is obvious that the breeding areas of anopheline mosquitoes will be more or less permanent in perennial streams, swamps, and seepages. In his article on mosquito control in the Federated Malay States, published in Byam and Archibald's "Practice of Medicine in the Tropics," Sir Malcolm Watson writes that "anopheles breeding places are generally well defined, permanent, and easily recorded on a map. They can be abolished at once by appropriate measures." The problem in Assam differs from that in the Federated Malay States, because in Assam anopheline mosquitoes generally migrate from dry-weather to wet-weather breeding places.

The effect of an unevenly distributed rainfall in a country like Assam has to be studied over the same terrain throughout the year, and preferably over a period of years, thoroughly to appreciate the seasonal changes in the characteristics and distribution of surface waters.

At the break of the south-west monsoon there is usually a complete change in the characteristics of the majority of the dry-weather breeding areas. This change varies with the composition of soil and the presence or absence of bacterial or vegetable contaminations. *During the cold dry season* the undisturbed waters in rivers and perennial streams on low-lying flat land are usually clear. During the monsoon season these disturbed waters are either continually or periodically muddy or laden with silt. Mud and silt and bacterial and vegetable contaminations on low-lying land during the monsoon season are therefore responsible for the migration of *A. minimus* to the uncontaminated clear malariogenic waters at higher levels. Bacterial (iron-oxide bacteria) and vegetable (red and green water-surface algæ) contaminations play a most important part in Nature in restricting the available breeding areas.

The prevalence of bacterial and vegetable contaminations on low-lying land is due to the high percentage of organic matter—i.e., a suitable food supply for these organisms in soils at low levels. Bacterial and vegetable contaminations are present throughought the year on more or less stagnant waters in drains, swamps, seepages, and pools, but are more prevalent during the steamy monsoon season when the temperature and humidity are more suitable for their growth.

The incidence of malaria on varying types of terrain is closely co-related to the clearness of surface water during the malaria season. Some breeding areas are continually dangerous throughout the monsoon season; others are periodically malariogenic, being affected by periodic high velocity of current or periodic contamination; while other areas, due to continual contamination with mud or silt or with vegetable or bacterial contaminations, are constantly free from *A. minimus* and other species of *Anopheles* which breed in clear water.

The importance of water contamination has already been pointed out by Watson. In his book "The Prevention of Malaria in the Federated Malay States," he writes: "Long before I had used oil in ravines I had noticed that the presence of the 'felted alga' meant the absence of *A. maculatus*, and I had noticed its association with pollution of water." The association of felted algæ with water pollution is common in Cachar. We have also streams and drains in Cachar where the water, when seen in dry intervals during the rains, is apparently clear but contains felted algæ. A visit to these streams and drains during a heavy shower solves the puzzle. It will be seen that during the downpour the water has become contaminated with silt, often milky in appearance,

which rapidly sediments after the cessation of the shower. Periodic contamination is also seen on healthy rice land, where the water may appear clear at dry intervals but becomes rapidly muddy during a shower.

A drought in the early part of the monsoon season considerably affects the incidence of malaria on low-lying terrain, for the effect of drought is to retard the period of migration of *A. minimus*—that is, increase of malaria on low-lying land. Likewise heavy rainfall or flooding in the early part of the year drives *A. minimus* from the now contaminated waters on low-lying terrain to the clear water at higher levels (an early formation of summer resorts) resulting in early epidemics of malaria on plateaux and high-lying lands, leaving the low-lying areas surrounded by contaminated waters as health resorts. The result is that during the normal monsoon season we have a paradox: health resorts are areas surrounded by healthy contaminated water, while areas with unhealthy clear water are death traps. Hence, by making drains, tanks, kutcha wells, pools, borrow-pits or other collections of water which remain continually clear during the malaria season mankind has unwittingly created much malaria. When periodically clear and uncontaminated over intervals long enough for the aquatic stages of *A. minimus* to be completed these areas may become periodically malariogenic. On low-lying land malariogenic water during the monsoon season is usually limited to the unshaded grassy clear water tanks used as drinking water supplies. Perennial streams are usually malariogenic only for short periods during the year—i.e., for about six weeks before and about six weeks after the south-west monsoon, but again the period of malariogenicity of perennial streams is entirely dependent on the soil composition of the area they drain and the amount of rainfall before and after the south-west monsoon.

Velocity of Current and Shade.

The second factor, high velocity of current, is an important but unreliable factor in mosquito control because variations in the rate of flow of a water channel are dependent mainly on the amount of rainfall. Further, high velocity of current is liable to erode the banks and bed of a water course and cause pockets or pools. Practical experience has taught me the dangers of pockets and pools. On several occasions I have found *A. minimus* safe and secure in the still water of a grassy pocket of a rapidly flowing stream. I have also frequently found it in the temporary pools left in water courses which only function as streamlets when there is continued rain. These dangerous temporary pools are most common during the north-east monsoon period or for a few weeks after the south-west monsoon. As a practical point when surveying a stream, I advise surveyors to walk against the direction of flow, as *A. minimus* larvæ are more easily caught when undisturbed by movement.

The third factor, the effects of heavy shade, is of the utmost importance when covering clear malariogenic waters. Clear malariogenic waters are usually above flood or contamination levels. The high incidence of fever on high-lying land in Assam has been well known for many years. That it resulted when heavy jungle was cut down and the land cleared for tea-planting was the experience and belief of at least one pioneer tea-planter of my acquaintance. My experience of the diseases among the local hill tribes has also shown me that the degree of malaria among the tribes living on the lower ranges of hills is intense. The reason is obvious when the areas are visited. Annually the hill tribes *jhum* (cut down and burn) the jungle to clear areas for the cultivation of hill-rice, thereby exposing streams, streamlets, and seepages. My predecessor, Dr. H. J. Glover, stated in 1910 that the commonest type of malarial attack in Cachar was "jungle fever." As synonyms for "jungle fever" Glover gave "bilious remittent fever" and "clearance fever." Had the "fever" been more appropriately named "jungle clearance fever," the *fons et origo* of the ill-health on many plateau and high-lying tea estates would have been recognised before the pathological importance of hookworms, a common factor on healthy and unhealthy tea estates, became unduly stressed and obscured the true cause.

The reasons why some anopheline species avoid shade whilst other prefer it have yet to be definitely ascertained. *A. minimus*, in common with most other anopheline species, undoubtedly prefers breeding areas where vegetation containing chlorophyll (grass, &c.) can grow, but extensive field experiences have given me the proverbial exceptions which prove the rule. On several occasions I have found *A. minimus* breeding in clear stony pools devoid of vegetation. Recently I also found larvæ sheltering in a small pocket of a stream covered with dense shade, and I have several times found the larvæ of the shade-loving *A. aitkenii* in clear grassy streams exposed to bright sunlight. The explanation in the latter cases is obvious when the areas are studied, as the larvæ have undoubtedly been accidentally flushed from their natural habitats to unnatural breeding places by a heavy downpour of rain. In the case of *A. minimus* the natural, grassy, exposed, known breeding place was only ten yards away from the heavily shaded sheltered pocket.

Laboratory Findings.

The results of my experiments in the artificial conditions of a laboratory have usually been contrary to my field experiences.

In the laboratory I have bred out *A. minimus* in water which was collected from a pool under heavy bamboo shade where the water was apparently contaminated with decomposing bamboo leaves. I have bred it out in darkened almirahs, in the water from "felted alga" streams, and in red iron oxide water, although the larvæ had an initial struggle to break the oil-like film. The thick scum of surface algæ, however, asphyxiates all anophelines—even *A. vagus*, a contaminated water breeder—within a few hours.

Mud and silt from muddy and silty waters rapidly sediment in hatching-bottles in the laboratory and *A. minimus* larvæ readily breed out in the clear supernatant water. Probably in nature, however, silt in suspension asphyxiates anopheline larvæ such as *A. minimus* from blockage of the respiratory organs. In its natural environment a certain degree of sunlight is apparently essential to provide the normal food-supply on which *A. minimus* larvæ feed, but until definite scientific reasons are forthcoming one can only conjecture that the habits of certain species of anopheles vary like those of the various races of mankind, who cease to procreate their species in unsuitable or unnatural surroundings.

Malaria Control.

In discussing the principles of mosquito control (loc. cit.) I stated that the practical application of Nature's methods of flooding or flushing can be artificially obtained in appropriate areas by mechanical means, such as sluice-gates, bunding, straightening streams, and silting loops. I would here like to emphasise the fact that, as a result of a further study of soil compositions, the appropriate areas where Nature's methods can be artificially applied by these means are very limited indeed. Flooding should never be carried out unless the resultant effect is effective water contamination; periodic flushing is liable to make pockets at the edges or leave pools in the stream bed. Bunding may result in a collection of dangerous clear water, and straightening streams, unless in very carefully selected areas, may not only be associated with the dangers which arise from flushing but, owing to increased velocity of the current, may increase the size of subsequent lower loops in the stream course.

For experimental purposes I have selected duranta to shade known dangerous narrow drains and streamlets, while *Cassia nodosa* or *javanica* has been selected for known dangerous broad main drains and streams. Duranta is the thorny privet hedge commonly seen around bungalow compounds. Animals will not eat it and, owing to the dense shade produced when thickly planted, it should simulate the degree of shade which is inimical to the habits of *A. minimus* and prove a cheap and permanent anti-malarial measure.

On broad streams under natural conditions I have found that heavy bamboo shade eliminates *A. minimus*. Unfortunately bamboos, which are used as building materials in house construction and for many other purposes, are liable to have an uncertain existence when they reach maturity in districts where bamboos are annually becoming more scarce. The two species of cassia, especially the indigenous *nodosa*, appear to be the most suitable type of shade for broad channels. These two species of cassia are rapidly growing leguminous trees, giving dense shade; they are deep-rooted, withstand storms excellently, and, like duranta, their foliage is not eaten by animals.

The more I study the malaria problems of Assam the more does the truth of Watson's statements in the Federated Malay States become apparent: "Work which leaves a trail of malaria behind is bad engineering. As we learn more, perhaps the time will come when we shall be able to say to one species of anopheles 'come' and to another 'go' and shall be able to abolish malaria with great ease, perhaps at hardly any expense." Man-made clear water-tanks, kutcha wells, pools and borrow pits, man-made clear water drains, exposed streams and streamlets, *and improperly constructed bunds or embankments* creating dangerous clear-water breeding areas, swamps and seepages where safe natural thick swamp vegetation has been cleared, are all found on the terrain on which I had been investigating malaria problems.

I have found that low-lying, well-shaded tanks are free from *A. minimus* during the rainy season. On careful examination it will be seen that these tanks are very easily contaminated with mud (rainfall and soil erosion) owing to the absence of a grassy-edged binding, because heavy shade prevents growth of vegetation. I have had no experience of well-shaded tanks at high levels, as all the tanks at high levels on the terrain under my supervision are exposed; I am carrying out experiments in this direction. I have attempted to contaminate clear water-tanks at high levels with surface algæ but, apparently owing to absence or insufficiency of an appropriate food-supply (organic matter) in high-lying clear water, surface algæ rapidly succumb. My researches have also taught me that work which can be carried out with impunity on *certain types of soil and strata* cannot be carried out on others, and that it is unfortunately easier to create malaria than to eradicate it.

The treatment of Assam's malaria problems is based on a complete knowledge in each area of the factors which are responsible for malaria, hence a thorough survey during the malaria season is absolutely essential. In the absence of definite knowledge of the effect of heavy shade around dangerous clear-water tanks, it is obvious that properly constructed wells or piped water-supplies would eliminate this source of man-made malaria. Dangerous clear-water pools, borrow pits, and functionless drains should be filled in. Exposed dangerous clear-water drains, streamlets, and streams should be covered with heavy shade. Swamps and seepages may be assisted to revert to their safe natural condition by replanting thick swamp vegetation such as tarapat. In many cases, however, and especially in the case of seepages, I have found it more practical—i.e., the areas can be brought more rapidly under control—to adopt Watson's drainage methods than to cover the resultant clear-water drains with heavy shade.

It should be clearly understood that there are in Assam many miles of harmless exposed waters in rivers, perennial streams, and drains; it would be a gross waste of human energy and money to cover these with dense shade or to fill in contaminated pools and borrow pits.

Until biological control can be restored, the cheapest and most effective method of controlling malaria is by larvicides, especially by oiling, but it has to be remembered that the control of malaria by oiling can only be compared to the control of the hyperglycæmia of diabetes with insulin; as soon as treatment is discontinued the disease returns. Further, cessation of control may be attended with disastrous results, owing to an increase in the non-immune population during the controlled period.

Clinical and Laboratory Notes.

A NOTE ON PAIN IN RELATION TO DUODENAL ULCER.

By Donald Macleod, F.R.C.S. Edin.,
HONORARY SURGEON, LEIGH INFIRMARY, LANCASHIRE.

The most important factors in the investigation of the cause of that particular pain which is associated with duodenal ulcer are the anatomical disposition of the first and second parts of the duodenum and the behaviour of the contained gas derived from the stomach after a meal, particularly its pressure effect in the first part. There are many types and varieties of stomachs and duodena, no two being exactly similar. In every case, however, the direction and anatomical lie of the first two parts of the duodenum, in relation to each other, are the same. The first part runs upwards and backwards, and is suspended at its termination by the free edge of the gastro-*hepatic omentum, being freely movable*. From here the second part commences and runs directly downwards, *being more or less fixed*.

The most extraordinary features of an active duodenal ulcer (by "active" I mean "unhealed") are that, no matter how full the stomach may be after a meal, the patient is entirely free from pain, and it is only when the stomach is nearly or quite empty that he complains of pain. In other words, a large amount of food will pass over the ulcer for hours on end without causing any pain whatever. Another common but nevertheless strange fact is that taking liquid or solid food when pain is present will soon relieve it. Several theories have been advanced to explain the cause of this particular pain, but they are not altogether convincing. Consideration of the possibility of distension of the ulcer-bearing portion of the duodenum by gas coming from the stomach may, however, help to elucidate it. There is always a certain amount of gas in an empty stomach. After a meal this is greatly increased, a fact easily confirmed by percussion. Most of the increase is said to be due to swallowing atmospheric air, but it is not unlikely that there is some actual diffusion into the stomach itself.

In the last 20 cases of duodenal ulcer which came under my care I introduced an Einhorn's tube into the first part of the duodenum, verified its position under the upright X ray screen, and inflated that part of the gut. In each case I was able to satisfy myself that at a certain point of distension the same kind of pain could be reproduced as that complained of by each individual patient. The volume of air introduced in each case varied. These patients ultimately underwent operation.

Pain due to After-coming Gas.

It seems to me, therefore, quite reasonable to suppose that distension by after-coming gas from the stomach is at least one possible cause of pain in active duodenal ulcer. This gas follows the meal out of the stomach, making its way towards the antrum and pylorus, and eventually filling the first part of the duodenum. Distension follows, and pressure in an already over-sensitive ulcer-bearing area of peritoneum results in pain. This pain is not colicky or griping, but rather an increasing ache, gradually reaching a point of maximal intensity, and as gradually falling and diminishing. This is what one may well expect from slow distension. Owing to the localised inflammation accompanying the ulcer, there is a certain degree of paralysis of that portion of the gut. This in itself is sufficient to delay the expulsion of the contained gas, but much more important is the arrangement of the second part of the duodenum. This part, in the erect posture adopted by man, lends itself very effectively to obstructing and resisting the exit of gas from the first part because of its vertical position and its immobility. The effect is distension followed by pain. The third part of the duodenum offers no such resistance, owing to the slightly upward course which it takes. Food, on the other hand, passes rapidly through the whole duodenum, if it may be assumed that an ordinary meal behaves in the same way as a bismuth feed in cases of duodenal ulcer. The direction of the second part is rather an aid to its progress. As the gas in the stomach becomes less, so does that in the first part of the duodenum. It is slowly evacuated, the distension lessens, and ultimately—although some still may remain—there is not enough to reach that point of distension which will create pain in that particular duodenum of that patient. The duration of the pain depends upon the time which it takes for the volume of gas in the first part to fall below this point.

The ages of my patients ranged from 18 to 53. All except four were males. Six ulcers were situated at the junction of the first and second parts, in the angle between the two. Four were on the posterior surface; two of them were so small that they were only seen on opening the gut. Ten were placed along the anterior surface between the pylorus and the termination of the first part. A partial duodenectomy was performed in three cases, and a gastro-jejunostomy in 17.

The time of onset of the pain bears no relation to the size or position of the ulcer, or to its distance from the pylorus. It simply depends upon the period which elapses between the ingestion of a meal and the beginning of the painful response by the over-sensitive ulcerated area to distension by the after-coming gas.

Treatment Directed towards Lessening Tension.

The more common methods of treatment of duodenal ulcer are:—

(1) *Diet.*—A restricted diet is usually given. This necessarily lessens the intake of air into the stomach. Sippy's method, in my opinion, owes its benefits to the continuous displacement of air at the pyloric end of the stomach. In much the same way the disappearance of pain on taking more food may be explained; it prevents the further addition of gas to the duodenum.

(2) *Drugs.*—Alkalis are freely administered. Their effect, however, is probably due to relaxation of stomach tone, and so to retarding of the passage of gas into the duodenum, rather than to their action in neutralising or diminishing the acidity of the contents of a "duodenal stomach." The accompanying hyperacidity is in all probability not the cause of pain, as this disappears on fasting; the acid content is highest, for instance, in the early morning, and pain does not appear until some time after the first meal. Belladonna is another drug commonly used. One of its principal actions is to relax tonicity, and the effect is much like that of alkalis in delaying the progress of gas into the duodenum. Effervescing drinks merely cause "belching," and so eliminate the gas which is already present in the stomach.

(3) *Posture.*—Rest in bed improves the condition of the patient, and the pain becomes markedly less or disappears altogether. This, I consider, is accounted for by the fact that the second part of the duodenum is changed from a vertical to a horizontal position, thus lessening the resistance to the outlet of gas from the first part.

(4) *Surgical.*—Gastro-jejunostomy is regarded as the most satisfactory form of treatment. I think the effect here is not the neutralisation of the acid by the bile, but the additional opportunity afforded for the escape of gas or some of it through the stoma.

All forms of successful treatment depend upon lessening tension in the first part of the duodenum and so giving rest to the ulcer, and an opportunity to heal. This can be brought about by reducing the intake of air, retarding and preventing the passage of gas into the duodenum, posture, and diverting the gas in the stomach.

Most of the literature on this subject abounds with a mass of technical detail and physiological assumption, and although the cases I have quoted in support of my contention may be too few, I feel sure, having observed and dealt with a large number in the past, that the explanations advanced by the various workers in this field do not fit the facts.

I am indebted to Dr. J. B. Higgins, radiologist to the Infirmary, for allowing me the use of his department.

A NOTE ON

HÆMOSTASIS IN THE MASTOID OPERATION.

By N. Asherson, F.R.C.S. Eng.,
ASSISTANT SURGEON, CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL.

In the course of the mastoid operation there are three separate stages in which the operator is confronted with hæmorrhage which has to be controlled before he can proceed. These stages are: (1) the incisional stage; (2) the osteal stage; (3) the plastic stage (in the radical or modified radical operation only). This division is both anatomical and practical, the bleeding being of a type peculiar to each stage.

Incisional stage.—The scalp has an exceedingly free blood-supply, so that incisions bleed very freely; the hæmorrhage is difficult to control and apt to prove more persistent than it is from incisions in any other part of the body. The bleeding arises from an anastomotic network of arteries, taking source from the posterior auricular, the occipital, and the superficial temporal arteries. The usual method of hæmostasis by artery forceps is time-consuming, and owing to the texture of the scalp no easy task. Moreover, ligatures tend to slip easily. An alternative procedure is to incise boldly down to bone and rapidly elevate the flap, ignoring the immediate bleeding, and controlling it by pressure of the retractor.

Osteal stage.—The chief blood-supply to the mastoid air cells arises from the stylomastoid branch of the posterior auricular, entering through the stylomastoid foramen, on the deep aspect of the mastoid process.

In the *plastic stage* the bleeding is from the vascular integument over the auricle, supplied by the posterior auricular artery.

The procedure to be described renders the incisional and plastic stage a bloodless one and will minimise to a surprising extent the bleeding in the osteal stage. It is applicable to adults and children. The method is not applicable to those cases in which a large *periosteal abscess is present over the mastoid.*

The mastoid area is prepared as usual, shaved and painted with iodine. The hair is kept off the field of operation by a broad strip of sticking plaster along the limits of the shaved area. This plaster is subsequently removed at the termination of the operation, while the patient is still anæsthetised. Ten minutes before the anæsthetic is begun the whole of the retro-auricular (mastoid) area is infiltrated with about 20 c.cm. of novocain solution (1 per cent.) to which about 8 drops of adrenalin solution (1 in 1000) have been added. The infiltration is from the mid-point of the incision, subcutaneous and also towards the periosteum. The needle is also carried along the posterior superior meatal wall and this region infiltrated. Another point to assist in a bloodless operation is to have the patient propped up at an angle of 30°. The sole function of this injection is to secure a bloodless operative field—it is in no sense a local anæsthetic.

The injection of the solution causes an ischæmia of the *tissues and this persists for over 60 minutes. The effect* produced is similar to that seen in the part of a limb distal to a tourniquet.

Stage 1.—The incision down to bone is through exsanguinated tissues. The exposure of the bone might well be as on the cadaver. There is no bleeding or oozing and no occasion to use an artery forceps; the whole exposure of the osteal operative field is performed in as many seconds as it usually takes minutes in the presence of hæmorrhage. Even the use of a swab becomes unnecessary in many cases up to this stage.

Stage 2.—As regards the osteal parts, the effect of the injection varies. In all cases the bleeding from the mastoid is minimised, and in some cases the oozing is so slight that the operative field is never obscured. Gentle dry swabbing at intervals will keep the field clear. The injection is carried along the posterior superior meatal wall, and thus the branch of the posterior auricular, which goes via the stylomastoid foramen to the air cells, comes under the influence of the injected solution. The vessel is "occluded" by the adrenalin and novocain and thus the blood-supply to the bone is diminished.

Stage 3.—At the end of the operation, when any plastic procedure becomes necessary—e.g., in the radical mastoid—the tissues are still blanched. The separation of the skin from cartilage is bloodless, and the removal of the cartilage therefore becomes extremely simple.

A CASE OF
EMPHYSEMA TREATED BY MECHANOTHERAPY.

By A. Kellgren-Cyriax, L.R.C.P. & S. Edin.,
PHYSICIAN IN CHARGE OF THE MECHANOTHERAPEUTIC DEPARTMENT AT THE ELIZABETH GARRETT ANDERSON HOSPITAL, LONDON.

The treatment of emphysema is still so unsatisfactory that I am encouraged to report the following.

In a series of cases I lately had a patient, aged 73, with undoubted emphysema and history of right-sided basal phthisis as a boy. From the latter recovery was complete, and his health was excellent until six years ago when periodic attacks of bronchitis had begun. In spite of wintering in warm climates he still had bronchitic attacks and gradually became so short of breath that he found walking on the level difficult and upstairs impossible. A recent attack of severe bronchitis had left him sitting bolt upright in bed unable to lean backwards or sideways because of the coughing these movements induced, hence getting very little sleep. He had much pain in the right side on coughing, and had been examined several times in the previous weeks, but no active tuberculosis had been detected; neither could I find any. All the usual medicinal treatment had been ineffective.

When called to him I found all the signs of emphysema. The patient was sitting up in bed, very breathless, with a severe spasmodic cough, a barrel-shaped chest with the usual kyphosis. The chest-wall was immobile, percussion note hyper-resonant, and breath sounds barely audible.

I treated this patient entirely on mechanotherapeutic lines, using chiefly passive and active exercises designed to strengthen expiration and in general to diminish the volume of the chest. These were:—

1. Strong manual vibrations over the front of the chest, and stimulatory nerve frictions on the upper four posterior dorsal nerves which communicate with the posterior pulmonary plexus through the anterior spinal nerves and rami communicantes.
2. During attempted prolonged expiration, intermittent pressures (about 5–6 per expiration) manually, over the upper lobe anteriorly, first gently, then more strongly.
3. Strong manual vibrations over the apices, and gentler vibrations on the trachea to loosen the sputum.
4. Short, sharp flicking clapping with the finger-tips to the chest and firmer hacking with the ulnar edge of the hands between the scapulæ.
5. General abdominal manipulation just below the diaphragm, especially the gastric area.
6. Petrissage and circumduction of the legs to remove œdema.

As soon as the patient's condition permitted the following exercises were added:—

7. The patient semi-reclining, stretching above his head his hands, grasped by the operator, approximated his elbows in front of his face, and during forcible expiration drew them downwards on to his chest, against resistance.
8. The patient sitting upright with straight arms abducted to a right angle, carried his arms forwards during forcible expiration against the resistance of the operator's hands placed on the patient's wrists.

The last two exercises were repeated three times, the pressure of the contracting pectoral muscles assisting expiration. The patient was also told to practise expiration by himself several times daily, a few breaths consecutively.

Treatment on these lines daily for a fortnight resulted in increased elasticity of the thorax, diminution of the barrel-shape and kyphosis, the breath sounds became more audible. The pain in the side had gone and the patient had not coughed for two days. Sleep was good and walking quite easy. Six months later the improvement had been fully maintained.

In the course of 30 years I have treated about 200 cases of emphysema and have failed in but two cases to improve the condition. Even if some of the manipulations may not be known to the practitioner, I believe relief would soon follow merely from *intermittent* pressures on the front and sides of the thorax, provided they are done evenly, gently, and elastically during expiration—followed by exercises 7 and 8.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY: SUBSECTION OF PROCTOLOGY.

At a meeting of this Subsection on Dec. 11th, Mr. Cecil Rowntree, the President, opened a discussion on

Complications of Operations for Piles.

It might be said, he remarked, that there should be no complications of an operation for piles on an otherwise healthy patient. But patients were not always healthy, and no surgeon was competent all the time. These operations were attended by so little risk to life that they were often undertaken lightly, without a competent anæsthetist or assistant, and by those who were scarcely qualified to carry them to a successful issue. The easier an operation, the greater was the discredit if anything went wrong, and it was essential to be fully alive to the possibilities of trouble, even in a straightforward case. In dealing with patients who were aged, infirm, diabetic, or paralysed, or who had damaged hearts, there was all the greater reason for care in the minutiæ. In a recent book he noted that 18 possible complications and 6 sequelæ were described in connexion with operation for piles. The Section ought to try to settle some of the outstanding questions on which the text-books at present differed. The choice of anæsthetic had been discussed elsewhere a week ago,[1] but it might be noted that the surgeon's position in these operations prevented his keeping a watchful eye on the thoracic end of the patient. Sudden and complete relaxation of the anal sphincter should suggest the need of added watchfulness.

At operation it might be discovered that the diagnosis was wrong or insufficient. The diagnosis should have been established with the proctoscope, but this need was not always realised in practice. There must always be a good light for the operation. If the case was really one of piles and the operation was satisfactorily completed, the surgeon was often confronted by the problem of post-operative pain. Some patients had little or no pain; others had severe pain which he could not account for. A clumsy operation caused more pain than one in which the tissues were gently handled, yet some of his patients had had pain despite his best precautions. Mr. Lockhart-Mummery laid stress on the importance of maintaining asepsis, but the President had not found that pain was abolished in this way. As the pain came on within 24 hours or less, he did not think it could be due to sepsis. Neither did post-operative pain appear to depend entirely on what operation was done. Some said that the cautery operation was less painful than the ligature operation. For a long time he had been employing the latter, and his strong impression was that the pain was less with this, also that the pain was less severe in women than in men, and less in the aged and feeble of both sexes than in the young and vigorous; hence it might have some relation to muscular vigour and to spasm of the levatores ani. If the pain was due to reflex spasm, what induced it? Probably it was a matter of attention to minor details of technique. In applying the clamp it was necessary to make sure that no sensitive nerve-endings were included in it. The question arose whether the sphincter ani should be stretched. The President thought that stretching was a help, but unless it was done very gently, the tissues might be so damaged as to do away with any advantage it would afford. Where pain was present after operation only one drug was available—namely, morphia—and he used it, though he knew that some people were suspicious of it. The doses given were often inadequate; to dole out gr. 1/8th of morphia to a strong 12-stone man was to ask for trouble.

---

[1] See The Lancet, Dec. 14th, p. 1258.

The most dramatic, and perhaps the most important, complication was hæmorrhage. Both recurrent (or primary) and secondary hæmorrhage followed, with varying frequency, every method of operating for piles. Could anything further be done to reduce the already small proportion of cases in which bleeding followed? He could only urge the need for attention to all the small details, such as avoiding bad anæsthesia, discarding ligature material which had been boiled once too often, and operating with deliberation. The strain on the ligatures was very great. The amount of blood coming away at one of these hæmorrhages would astonish the uninitiated, and inspection of the rectum through a speculum during such hæmorrhage needed caution for the observer's own sake. The bleeding-point had to be found and tied, and it was essential to have a good anæsthetic and a number of sponge forceps to grasp the soft and yielding blood-stained tissues without damaging them. Secondary hæmorrhage was more troublesome and more difficult to deal with, and it seemed clear that it was due to sepsis; it was strange that it did not occur more often. In this form of hæmorrhage the difficulty of finding and securing the bleeding-point in what might be a sloughing area was so great that the best results were obtained by plugging or packing the rectum. Sometimes a stricture formed after a hæmorrhage; both might be the result of sepsis in the operation area.

Another complication was retention of urine. Most of the books said that this ought not to occur after a properly performed operation for piles; yet the same books—assuming its occurrence—gave several alternative methods of dealing with it. This complication might follow every type of operation, and it would be well to know how it could be avoided. He thought it was partly the fault of the surgeon, and that trauma was a factor. It was relatively commoner in vigorous young adults, and he had not yet heard a convincing explanation for it. The passing of a catheter should not be left too long, for if the bladder was over-distended, catheterisation might have to be repeated. Post-operative retention was less common in women than in men. An important pitfall was unrecognised prostatic enlargement; the patient might not have had sufficient cause to seek advice for his prostate, but the rectal interference might be the last straw, and set up a train of prostatic symptoms. Other complications might be more or less coincidental. Thus, he had been asked to see a middle-aged muscular man who had been vomiting for three days after an operation for piles. His abdomen was distended and he had intestinal obstruction; a volvulus, already gangrenous, was discovered, and he died the same day. The speaker thought that the volvulus had been caused by post-operative vomiting. Sometimes fissure in ano developed during convalescence, but, as a rule, he considered the fissure was present before the operation was undertaken; it was overlooked through being tucked away between two piles. This, again, emphasised the need for good light and efficient exposure. The rarity of abscess and fistula after pile operations was a testimony to the care usually exercised in them.

In conclusion, the President pointed out that the patient who exchanged his piles for a stricture was reminded every day of his life what a bad bargain he had made. It was tempting to call strictures in one's own work "traction bands," and he wondered how far these bands were preventable. Occasionally they occurred after operations carried out under the best conditions. Were they due to fibrosis and contraction of the submucous layers, and was there agreement about the relative frequency of stricture in various types of operation? Was it less common in the operation in which the whole pile was ligatured en masse, without transfixion, or cutting except for the V-shaped incision in the skin, or after an attempt had been made to strip up the pile from the rectal wall until a definite pedicle was made, transfixing with a ligature? In the second there was certainly a raw surface left to granulate up, and so one which was exposed to sepsis. No detail should be considered too insignificant to demand attention.

Discussion.

Mr. **Haslet Baldwin** said he had seen but few cases of hæmorrhage after operation for piles. He agreed that maintenance of asepsis would prevent many complications. He always swabbed the rectum with an antiseptic before beginning the operation. After operating he gently dilated and examined the mucous membrane to see whether a stricture had formed. He never dilated the sphincter.

Mr. W. B. **Gabriel** held that post-operative ulceration was an important complication, because it led to chronic disability and needed prolonged after-treatment; and even so it might never return to normal. Operation should never be done on a septic pile; if ulceration was present it should be treated on expectant lines, with antiseptic compresses, and the patient in bed. A 5 per cent. solution of carbolic acid in oil gave good results in bad piles. For internal piles the Whitehead operation should not be done. He had seen severe complications after the clamp and cautery operation. The ligature operation was the method of choice. During the last year he had used local anæsthesia, which gave full relaxation of the sphincter. Post-anæsthetic vomiting was to be avoided in order to prevent external œdema. Piles should not be stripped up high. Ligation at the level of the anus reduced secondary hæmorrhage. Catgut was superior to silk because it gave smoother and more rapid healing.

Mr. **Cyril Norbury** said that at one time he did the high stripping operation and had a number of strictures. He now ligatured a little above the anal margin, and his results were better. He had had two cases of that serious complication, suppurative pylephlebitis, one of which had proved fatal on the eighth day. Absolute asepsis in the anal region could not be secured and the possibility of suppuration in the liver should be in the surgeon's mind. Another uncomfortable complication was irritation after the operation. Some patients had marked pruritus ani after it, but fortunately this responded as a rule to local measures.

Mr. E. T. C. **Milligan** spoke of strictures of the anal canal after pile operations, a complication which he contended could be avoided. The site of the stricture ring was the upper third of the anal canal. In a series of 282 operations stricture occurred in 32 (11·3 per cent.); while in another series of 290 there were 27 strictures (9·2 per cent.). When three or four large piles were removed by stripping up, a large bare ulcerating surface was left, and this, encircling the canal, might result in stricture. Ligature at different levels to obviate this complete encircling had been suggested but could not always be satisfactorily carried out. He did not strip the pile off the anal canal, and he left a good area of healthy intact skin and mucous membrane between the ligatured hæmorrhoids. If a constriction ring did not develop immediately after operation it would not develop at all.

Mr. V. Warren Low thought that most of the complications met with in hæmorrhoid operations were due to leaving raw areas. He carried out the operation devised by Mitchell, of Belfast, and never removed more than four separate hæmorrhoids. He had not had stricture in his cases and he had not seen hæmorrhage follow. In retention of urine in these cases he thought there was a large functional element; it was expected, and doctors for that reason generally complained of it in themselves after this operation.

Mr. W. S. Perrin said his practice was to divide the pecten band, and pain was practically non-existent in the first 24 hours. He objected to dilatation of the sphincter, and he had not had hæmorrhage after the ligature method. He preferred the old-fashioned ligature operation.

Cases were shown and discussed.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

A Fatal Case of Diverticulitis.

A meeting of this Section was held on Nov. 29th, Mr. R. Atkinson Stoney, the President, in the chair.

Sir William Wheeler described the clinical course of a fatal case of diverticulitis which perforated into the free peritoneal cavity. The patient, a man aged 44, had previously been healthy. Half an hour after a dose of salts, when his bowels had acted, he developed an excruciating pain in the left iliac fossa. He was seen within an hour, and the signs and symptoms were then exactly similar to a recent perforation of the duodenum or stomach, except that all were in the left iliac fossa. There was no difficulty in diagnosis, notwithstanding the absence of history. No left-sided appendicitis could have developed with such dramatic suddenness. The bowels had acted well. There was no distension, and the picture was one of inflammation and not of obstruction. Within three hours the abdomen was opened to the left of the middle line below the umbilicus. The pelvic colon was found loose (exceptional in diverticulitis) and the perforation was dealt with by leaving the loop of colon outside the abdomen. Subsequent resection by the Mikulicz method was contemplated. The cæcum was drained. The following day ominous black vomiting became almost continuous. Lavage only produced temporary relief. A high jejunostomy was performed under gas-oxygen and local anæsthesia, but here again the loop failed to drain. Enemata were introduced by a catheter through a stab in the extruded colon, but no evacuation resulted. Vomiting continued. The patient was induced to swallow a duodenal tube, and by means of this a total of three pints of orange-coloured material was aspirated in 12 hours. At first the patient's condition improved considerably following aspiration, but later there were signs of starvation from the loss of duodenal contents. A somewhat similar case published by D. P. D. Wilkie was quoted. Sir William Wheeler pointed out that in persistent high obstruction the surgeon was faced with a dilemma. On the one hand the duodenal contents were extremely toxic, on the other loss of these contents for any prolonged period produced a physiological death. He had adopted Wilkie's plan in a modified form. The fluids aspirated from the duodenum were immediately injected through the jejunostomy. Following this procedure, drainage commenced through the cæcal tube. Peptonised milk, panopepton, and other foods also were given through the jejunostomy. On the fifth day the patient announced that he felt at last he was going to recover. This improvement lasted for six hours, but a relapse followed. Regurgitation recurred, and the patient died. Twelve pints of 10 per cent. glucose solution combined with insulin were administered intravenously during the five days. Continuous saline was given by the drop method into each axilla. During the first three days the patient appeared to be in a condition of alkalosis and some tetanic spasm was noticed. Administration of calcium and increased quantities of chlorides together with glucose proved effectual. Towards the end, air-hunger, combined with diacetic acid and acetone in the urine, indicated acidosis. During the six hours in which recovery seemed likely the material drained from the cæcum contained bile. The bile was not mingled with the other contents but came away separately. Sir William Wheeler had noticed in some cases of chronic pancreatitis the bile did not mingle with the characteristic clay-coloured stools. There was evidence in the case described of insufficiency of both liver and pancreas.

Discussion.

The President referred to the fact that the cæcum had been brought out through the main incision; if a separate opening had been made on the opposite side, the cæcum might perhaps have drained itself and prevented the high obstruction.

Mr. A. Chance was inclined to think that the vomiting was not mechanical but toxic, and suggested that the whole condition might have been toxic.

Mr. H. Stokes wanted to be clear that there really was a diverticulum. He had come across many cases of perforation of the large intestine without diverticula. It was fatal to put tubes into dilated gut for drainage purposes.

Mr. F. J. Henry said that free perforating diverticulitis was a great rarity. In the only case in his experience there was no difficulty in closing the perforation and the patient recovered fairly easily.

Reply.

In reply, Sir William Wheeler said that the cæcum was loose and it was possible to perform cæcostomy through the primary incision. He believed that the obstruction which followed septic peritonitis was usually mechanical. Loose adhesions between loops were the cause of obstruction. The loop of bowel was removed after death, and the perforation of one of many diverticulæ demonstrated.

Mr. Oliver Chance read a paper on Some Experiences in an English Radium Clinic.

PAN-PACIFIC SURGICAL CONGRESS, HONOLULU.

(From our Australian Correspondent.)

Representatives of all the principal races bordering on the Pacific attended the Pan-Pacific Surgical Congress at Honolulu from August 14th to 23rd last.

A Honolulu Hospital.

The 13 delegates from Australia and New Zealand reached Honolulu four days before the Conference, and had a chance of studying the wonderful Queen's Hospital, built by public subscription, and containing 280 beds. It is under the directorship of Dr. Nils Larsen, a Swede of great ability and organising power, and it has reached a high level of efficiency.

Ninety-eight per cent. of the income comes from patients; the city and county pay for indigent persons who have been resident for more than five years, and there are 30 endowed beds for waifs and strays. Ward patients pay 10*s.* a day. Private wards are from £2 a day. The meals are brought to each patient, even in the ward, on a tray with a linen cloth and a vase containing one flower to give a home-like touch. The name of each patient is on a card on the treaty, and these cards are of different colours according to the diet, so that the sister in charge can see at once that no mistake has been made. The lighting of the wards at night is from a diffused dull electric light in the floor, which cannot be seen by the patient, but is sufficient to guide the sister to the different beds.

There are five resident medical officers in the hospital, and every man in the city who is a member of the medical society is entitled to send in patients under his own care. This, of course, complicates the work, and does not make for the most expert treatment of the patient; but the disadvantage has been countered to a certain extent by the director, who has instituted weekly meetings of all those entitled to send in patients. At these meetings every week any untoward event is brought up for discussion and criticism. The name of the medical man is suppressed, but, of course, is known to most of those present. The criticism is unsparing, and even if the responsible doctor has not attended the meeting he is very soon informed of it by his colleagues in the town. Another feature of this hospital is that director, residents, and nurses are regarded as one unit, having but one object in view. Thus when lunch was given to some of the selected delegates it was attended by all those members of the staff who could be spared, including nurses.

Hospital Standardisation.

An afternoon was devoted to a discussion on hospital standardisation which was illustrated by exhibits, including a model of the new King County Hospital of Seattle, which is considered the most modern hospital supported by charity. Another exhibit showed the standardisation of sponges used at operation. This subject was investigated throughout America, and it was found that the different varieties in use numbered over two hundred. These were standardised and seven varieties only are now recommended. Dressings have been dealt with in the same way.

Prof. O. JEFF MILLER (New Orleans) said that in the 12 years since hospital standardisation began in America it had spread into every branch of hospital work. Its annual survey included 3000 hospitals, of which nearly 2000 were on the approved list.—Dr. M. T. MACEACHERN explained hospital standardisation:—

It is a movement, he said, which has been carried on by the American College of Surgeons during the past 12 years with the object of providing better service to the patient. An annual survey of all hospitals of 25 beds and *over is carried out. The rating of each hospital is based on* what is known as the minimum requirements, of which the fundamental principles are: a properly organised medical staff; regular conferences for review and analysis of the clinical work; accurate and complete case records; and adequate laboratory and X ray facilities under competent supervision. This movement has done much to reduce the average stay of patients and mortality-rates in hospitals.

Surgery of the Alimentary Tract.

Prof. MILLER emphasised the need for early diagnosis and rapid operation in cases of intestinal obstruction. "This was a condition," he said, "in which the lowest mortality is achieved, not by the conservative surgeons, who operate only on definite diagnoses and for whom, ordinarily and properly, we have only praise, but by that other group of enthusiasts, whose resort to the knife is immediate, and for whom, ordinarily and properly, we have only condemnation. Their craftsmanship may be dubious, their surgical judgment is unquestionably dubious, but in this one contingency at least we should do well to emulate them, for they lose the fewest patients from this deadly disease." He outlined the medical *and surgical treatment in detail, and stated "that* the mortality rises approximately 1 per cent. with each hour of procrastination, and any mortality over 10 or 12 per cent. can be charged only to delay. The death-rate, which is popularly quoted as 30 or 40 per cent., actually is 55 or 65 per cent., and we are only stultifying ourselves when we refuse to face the true figures."

Prof. J. R. B. BRANCH (Shanghai), in a communication on the surgical treatment of intestinal tuberculosis, said that pictures after a barium meal showed two striking things—hypermotility due to ulceration, and filling defect in the cæcum and ascending colon, which might be due to hypermotility or actual *stenosis. Surgery was clearly desirable in some* borderline cases, in cases with stenosis, and in those which had resisted thorough medical treatment.

Dr. A. O. LOE (Seattle), speaking on acute perforation of peptic ulcers, pointed out that early diagnosis and operation were imperative. The mortality-rate was directly proportional to the time intervening between perforation and operation. Simple suture was a safe routine. Resection and suture might require secondary operation later, owing to obstructive symptoms or disturbed physiological action. Resection with Finney or Horsley pyloroplasty was the more ideal operation in early cases, *relieving symptoms and producing more normal* physiological relations between stomach and duodenum. The mortality-rate was low. Resection and gastro-enterostomy was indicated only in cases of large calloused ulcers and immobility of the duodenum.

Dr. HORACE J. WHITACRE (Tacoma, Washington), in a paper on duodenal surgery, said that loss of appetite, nausea and vomiting, dizziness, general malaise, and a great variety of vague abdominal symptoms were duodenal in origin. Duodenal adhesions secondary to cholecystitis, duodenal ulcer, duodenitis, and other abdominal conditions could and did cause these symptoms. "I now," he said, "look upon duodenal mobility and an unhampered duodenum as an objective, which, from the viewpoint of a complete cure, outweighs in importance the removal of the gall-bladder in a case of cholecystitis with adhesions." He described a peritoneal plastic operation which would restore free peristaltic mobility to the duodenum and which would cure the symptoms.

Goitre.

Dr. DAVID C. HALL (Seattle) reported observations on 30,000 students of the University of Washington, and said he had found the incidence of goitre to be high on mountain range slopes and low on plains and Puget Sound islands. Recent years show a marked decrease due to education, iodised salt, and iodine tablets.

Dr. CHARLES L. MIX (Chicago) said that adenomatous goitre could be wiped out by the administration of proper amounts of iodine to all pregnant women; in this respect veterinary surgeons were ahead of physicians. In pure adenoma, the administration of iodine might do harm instead of good. Dr. Mix was emphatic in his belief that any adenoma should be removed surgically as soon as discovered. Goitre of non-toxic type might become toxic at any time, *through abnormal innervation brought on by fright* or a number of other causes.

In goitrous regions one-third of the girls and one-fifth of the boys showed thyroid enlargement. The reason for the excess in girls was that they must store up enough thyroid secretion to last their offspring for a certain length of time. If they were unable to do this owing to an insufficient supply of iodine in food or water, the thyroid gland would enlarge by way of compensation in an effort to increase its secretion by increasing its capacity.

Dr. J. RUSSELL WELLS (New Zealand) stated that he had known a few instances of goitre in Maoris, but this was in a district where the Maoris had largely adopted the customs of the residents of British origin. He agreed with Dr. Mix that all adenomata should be removed.

Dr. R. E. MCKENCHIE (Vancouver) maintained that an ultramicroscopic organism is the probable *cause of goitre, while absence of iodine makes people* vulnerable to invasion by the organism.

The Lungs and Bronchi.

In a symposium on bronchoscopy and thoracic surgery, Dr. EMIL HOLMAN (Stanford University, California) read a paper on post-operative intrapulmonary abscesses. "An analytical study of 1908 cases of pulmonary abscess shows," he said, "that 29·6 per cent. followed some operation, and more than half of these followed tonsillectomy. The available experimental evidence corroborates clinical impressions that intrapulmonary suppuration may be produced both by the intrabronchial and intravascular routes. There is no experimental evidence to support the theory that the lymphatic system is a factor in the production of intrapulmonary suppuration."

Dr. **Leo Eloesser** (Stanford University) spoke on chronic bronchial stenosis. Whilst tracheal stenosis and acute bronchial stenosis (foreign bodies and massive collapse) had been closely studied, not enough attention, he thought, had been paid to the chronic condition. The causes were sometimes congenital and sometimes took the form of compression due to tumours, inflammatory processes, or foreign bodies. He uttered a warning against the use of iodides, and spoke of the danger of placing the patient on his sound side in the hope of draining secretions from the affected side.

"Stenosis is important," he concluded, "not only in theory but in practice. There is much to be done for it. There is also reason to suspect that bronchial stenosis is more frequent than has been supposed, and that it has been responsible for more pulmonary damage than has been cast to its account. I am convinced that lipiodol, the bronchoscope, and familiarity with these pictures will make bronchial stenosis a common disease."

Dr. **E. D. Roberts** (Honolulu), in a paper on iodised solutions as aids in X ray diagnosis, discussed the various methods of combining iodine with oleaginous and other subjects, and described some original experiments. He had first tried corn oil as a base for the solution, but now exclusively used "kukui" oil, a Hawaiian product. This oil had proved very satisfactory and was inexpensive.

Diseases of the Eye.

Dr. **Lloyd Mills** (Los Angeles) presented a cinema film illustrating the prevention of complications in the surgery of cataract. The modern preparation for the operation, he said, had largely eliminated many of the former difficulties. Vitreous prolapse, which resulted more from the patient's sudden reaction to unexpected pain than from heavy-handed surgery or predisposing ocular disease, had been reduced by adequate mental preparation for operation, perfect anæsthesia, and full suture of the wound. The use of a full conjunctival flap and its complete suture was applicable to any form of cataract extraction, save that with corneal incision. The difference between the final results of intracapsular and extracapsular operations in the hands of equally experienced surgeons who used full closure of the wound by flap and suture should depend solely upon the reaction of the eyes to retain lens substance.

Sir **James Barrett** (Melbourne) read a paper on visual standards for mariners and railway officers. In men of the first class, he said, the initial vision should be 6/6 in each eye, with normal eyes and colour vision and an error of refraction not exceeding 1 dioptre, including 0·5 of astigmatism, with a little flexibility as regards the error of refraction. For less responsible positions a larger error of refraction could be permitted if there was no eye disease. The vision of all those concerned in a railway or marine accident should be re-examined before they were allowed to resume duty.

Leprosy.

Dr. **Forrest J. Pinkerton** (Honolulu), reviewing 700 cases illustrating the surgery of the leprous eye, said that early surgery upon the lid in orbicular paralysis was imperative and should be done before corneal changes have begun. In iritis early medical treatment was essential. Novocain infiltration was the operation of choice for all surgical procedures on the leprous eye.

A demonstration of clinical leprosy was given at Kalihi Receiving Station.

A rural community has been established on a peninsula of the island of Molokai, in which the inhabitants live without restriction and enjoy all the privileges of an ordinary community. They may even marry one similarly afflicted, but children are removed from the settlement immediately after their birth. To this settlement are sent lepers, whose progress towards convalescence is slow or have become a burden to their friends, but before being sent there every individual is legally entitled to remain for six months at the Kalihi Hospital, which acts as the receiving station for the territory. Here they may be examined by three physicians: one selected by the Board of Health, one by the patient, and the third selected by the former two; or they may elect to accept the diagnosis and recommendations of the physicians in attendance at the hospital. Provisions are made for subsequent examinations in cases of doubt. *No children under 15 years of age are transferred to the* Settlement except at the wish of their parents.

Dr. **J. T. Wayson** said that since leprosy was first introduced into Hawaii it had spread rapidly. Fifty years ago there were two known cases to every hundred of the people. Since 1890 the annual number of admissions had continuously though slowly fallen.

Neuro-surgery.

Dr. **George W. Swift** (Seattle) gave an address on the dural venous sinuses and choked discs. He upheld the view that choked disc was mechanical in origin and caused by a damming of the venous blood, resulting directly or indirectly from pressure upon the cavernous and petrosal sinuses.

Dr. **Steele Stewart** (Los Angeles) presented a paper illustrated by cinematograph on a possible explanation for the effects observed following ramisection in cortical rigidity. He suggested that they were due to a segmental vasodilatation of the vessels of the cord, resulting in a lessened irritability of the anterior horn cells.

Dr. **E. B. Towne** (San Francisco) and Dr. **Makoto Saito** (Japan) read papers on radiographic localisation of cerebral tumours, and the latter showed a film demonstrating the technique of a fascial transplant from the thigh to replace adherent dura, excised in a patient suffering from traumatic epilepsy. For demonstration of the arteries of the brain he had, he said, discarded the sodium bromide recommended by Moniz and used an emulsion of lipiodol. The emulsion was injected through the superior thyroid artery after a temporary clamp had been put on the common carotid and external carotid arteries. The size of the droplets of the emulsion used was larger than a red blood corpuscle, but smaller than a white blood corpuscle. This method had been used in 40 instances without any untoward result.

Prof. **W. A. Osborne** (Melbourne) delivered an address on the surgical applications of recent advances in physiology. Dealing first with anæsthesia, he said that doses of atropine should be on the low side, since the absence of secretion removed a natural protection. Speaking of the so-called nerve patterns he maintained that "tendon transplantation is physiologically a far sounder procedure than any form of nerve implantation or nerve graft." Later in his paper he said: "The alimentary canal has duplicate chemical plant, but has only one tube for transport. Disorders of digestion are disorders of motility. Let the surgeon therefore satisfy himself about the motility, and let the chemistry look after itself."

Cancer.

Opening a symposium on cancer, Dr. **Edwin I. Bartlett** (San Francisco) pointed out that in cancer of the breast the earlier and smaller and more hopeful the lesion the more thoroughly should the operation be performed.

Mr. **Frederick L. Hoffmann** thought that in general cancer statistics were of little practical value. Most cancer discussions concerned cancer deaths and their relative incidence to a given population, often only roughly estimated. The calculation of specific death-rates by sex and for different age-periods involved a knowledge of data often out of reach. Hence the extreme urgency that it should be understood that most statistical conclusions were only a rough approximation to the truth. The questionaire method of research, while very useful, had endless fallacies.—At another meeting Mr. Hoffmann gave a detailed analysis of the cancer mortality records of

Hawaii for the five years ending June, 1928. The general cancer death-rate is low as compared with the United States registration area. The most outstanding feature of the analysis is the extreme rarity of cancer of the breast in Japanese women.

Out of 125 Japanese females dying from cancer during the five years under review, not a single death was attributed to cancer of the breast. For Chinese women, however, the proportion dying from cancer of the breast was 16·7 per cent. This compares with 6·1 per cent. for all races, 6·9 per cent. for Hawaiians, 8·0 per cent. for Caucasians. Unfortunately, for many of the races, the numbers are too small for a generalisation.

Amœbiasis.

Dr. Y. S. **Lee** (Korea) reviewed 200 cases of amœbic liver abscess treated at the Severance Hospital since 1912. The first 100 were treated by open operation; of the second 100, 27 were treated by operation and 73 by aspiration. Ludlow, in 1920, had reported 160 of these cases.

In discussing the predisposing causes he stated that climate would appear to have a definite rôle in producing liver abscesses in those who were not accustomed to tropical conditions. The incidence in the native army in India was 0·6 per cent., whilst in the European army it was 7·4 per cent. Whilst in India white people would appear to be predisposed to the condition, in Korea the figures showed just the opposite. Race in itself seemed to be an unimportant factor. The disease was much more frequent in males, but 19 females were affected in the 200 cases; of this there was no explanation. The use of alcohol appeared to be an important predisposing cause to liver abscess.

Indigestion was a constant symptom and was sooner or later followed by pain in the right lower chest or hypochondrium, attended in most cases with fever, sweating, and chills. A sign of the utmost importance was deep-seated pain in the region of the abscess elicited by a sudden thrust with the end of the finger. This was important not only for diagnosis, but is a guide for the insertion of the aspirating needle. Enlargement of the liver and bulging of the intercostal spaces occurred during the chronic stage, and when the abscess formed near the surface it may rupture into the abdominal cavity, pleural cavity, lung, abdominal wall, and, more rarely, into one of the adjacent hollow viscera.

In treatment, the early and energetic treatment of amœbic dysentery with emetine and the prohibition of alcoholic drinks was almost specific. In the early or presuppurative stage emetine alone was usually sufficient for a cure; when pus had formed aspiration of the abscess with subcutaneous injections of emetine was the method of choice. Aspiration should, as a rule, be repeated in from five to ten days. Open operation had been abandoned except for cases of mixed infection or sinus formation.

Surgical aspects of the treatment of bubonic plague were dealt with by Dr. **Wu Lien Teh** (China), and Dr. **Teishin Seo** (Japan) read a report on the results of splenectomy for the splenomegaly due to chronic schistosoma infection, which is endemic in various districts of Japan. He also demonstrated specimens of mycotic splenomegaly.

Medical Education in China.

Dr. F. C. **Yen** (Shanghai) said that great strides had been made in medicine, public health, and sanitation since the formation of the Nationalist Government in China. Work was unified under the Ministry of Health, and rules are being drafted for licensing medical practitioners. A national midwifery board had set up a standard for the practice of midwifery, and has just opened its first training school. A big modern hospital had been established in Shanghai for treatment, research, and the training of students and nurses; it was to be dedicated to the memory of a medical man, "who unified China and conferred great blessings on her 400,000,000 people—Dr. Sun Yat Sen." In China there were 24 medical colleges; 11 were Chinese, 7 were controlled by missionaries, 2 were under direct foreign control, and the remainder were managed jointly by Chinese and foreigners. The total number of students was 2050, whilst the number of practising physicians is estimated to be 4500. China thus had but one medical school for each 16,000,000 of population, and but one doctor for every 90,000 of population. After praising schools established by missions and by groups of Chinese and foreign citizens, Dr. Yen spoke of the type of medical school in China, which was controlled, conducted, and financed entirely by foreign Governments, as represented by the Medical Department of Hong-Kong University and the Japanese Medical College in South Manchuria.

> "While they have all helped in turning out doctors, yet it raises a very serious question as to whether their contributions are for the ultimate good of the Chinese medical profession. What China needs is a united profession, not one divided up into cliques, engaged in the less profitable work of proselytising British, French, German, American or Japanese medicine."

Anæsthetics.

Dr. **John S. Lundy** (Rochester, Minn.) read a paper on agents and methods used for the induction of anæsthesia in the Mayo Clinic from 1922 to 1928. Local anæsthesia alone or in combination had been employed, he said, in more than half the operations performed. The use of chloroform had been discontinued and had been supplanted by ether. The custom of giving ether by the semi-drop open method was decreasing, but there was an increase in its use through the anæsthetic machine. Dr. Lundy laid stress on the good results obtained with acetylene at the Mayo clinic. "With acetylene," he said, "it has been possible to produce anæsthesia and relaxation, with quiet breathing, without anoxæmia and without the necessity of adding ether." Besides ethylene, there had been an increase in the use of nitrous oxide, ethyl chloride, and carbon dioxide.—In a paper on anæsthesia for operations in the lower part of the abdomen Dr. Lundy said that the choice of anæsthetic was of less importance for the lower than the upper abdomen, but open ether was probably the method of choice. Nitrous oxide and ethylene, especially with ether, was often frequently indicated. It was with operations in this area that spinal anæsthesia found its greatest usefulness. "Surely," he said, "there is no place in anæsthesia for any method to be used as a routine, and with so great a variety of agents and methods at one's disposal there is no acceptable excuse for fitting the patient to the anæsthetic rather than the anæsthetic to the patient."

In the course of a further paper Dr. Lundy referred to the derivatives of barbituric acid, and especially sodium iso-amyl-ethyl-barbituric acid, generally known as amytal. Apart from its other uses, it appeared to be of great value in sea-sickness.

He reported the use of this drug in 1000 surgical and non-surgical conditions. In 617 surgical cases there was little if any delirium, rarely any nausea, and no difficulty with respiration; in the non-surgical cases amytal was used for such purposes as controlling convulsions—e.g., tetanus, hiccup. It was used with carbon dioxide and oxygen in these cases. Amytal was also of value in the treatment of post-operative psychoses and delirium. Following operation after the use of amytal, sleep lasted from 12 to 72 hours. After discussing the disadvantages, which seem to result largely from large doses, he stated that the barbiturates had many practical uses.

Urogenital Surgery.

Mr. S. **Harry Harris** (Sydney) reported that he had performed suprapubic prostatectomy with complete closure in 104 out of 112 consecutive prostatectomies, included in which were 15 two-stage operations. Of the 104, two patients died, one of pneumonia and the other 48 days after operation. Of the 112 cases, post-operative suprapubic drainage was necessary in eight. Complete control of hæmorrhage was accomplished by suture; further, obliteration of the prostatic cavity and reformation of the prostatic urethra was performed. He thought that "the comfort of the convalescence from the patient's point of view, and the simplicity of the nursing, are in marked contra-distinction to that usually experienced after the usual method of suprapubic drainage."

Mr. J. **Jenkins** (Dunedin) read a paper on the diagnosis and treatment of stone in the ureter. He said that after clinical and radiographic examination, investigation should be done under spinal or caudal *anæsthesia.*

After cystoscopy with an indirect cystoscope, this is changed to a direct instrument and a wax-tipped catheter passed along the ureter well lubricated with oil. This is passed beyond the stone, and if possible several catheters are then passed. The wax bulb is now withdrawn until it comes into contact with the calculus. With the stone thus gripped, intermittent elastic traction is applied by fixing a rubber band at one end to the catheters and to the leg at the other end. After two to three days the catheters work down with or without the stone; if without, the process is repeated a week or ten days later. If it is impossible to pass a catheter or bougie beyond the stone, several attempts are made, and, if still unsuccessful, operation is performed. If infection is superadded to obstruction, operation should be performed at the earliest possible moment. One tends to operate early, if the stone is very large, is impacted high up in the ureter, or infection of the kidney is present.

Dr. **ALEXANDER PEACOCK** (Seattle), speaking on the treatment of the neoplasms of the bladder, commented on the growing tendency to regard all neoplasms of the bladder as potentially malignant. Electric coagulation applied through the cystoscope seemed to be the most efficient treatment so far devised.

Fractures.

In a symposium on industrial surgery, Dr. **L. L. GOODNOW** (Washington) pointed out that fracture of the spine and skull were not always treated satisfactorily. In fractured spine all cases which did not clear up quickly should undergo laminectomy; fixation should be done at the same time by inlay graft. Lumbar puncture was indicated if operation was not done. In fractured skull the quantity of fluid removed by lumbar puncture should not be sufficient to reduce the pressure more than one-half at any one puncture. Compound fracture of the skull, as a rule, caused less temporary and permanent disability than the moderate so-called closed fracture. All depressed fractures should be elevated, and decompression should be performed in chronic œdema of the brain and all severe concussions with elevation of intracranial pressure. In another symposium Dr. **L. R. CHANDLER** and Dr. **J. T. WATKINS** (San Francisco) communicated a paper on non-union. This paper was an appreciation of the work of the late John Cowan of San Francisco.

The essentials of Cowan's operation are: to elevate the periosteum for a short distance on either side of the fibrous bond; to remove the fibrous bond; to open up the medullary spaces of the end of the fragments; and to prevent the recurrence of fibrous tissue ingrowth between the fragments. This is done with a portion of rib, split into halves. The thin cortex of rib is rolled up into a band or cut into short segments and inserted under the periosteum, about the ends of the fragments at the fracture line, and the periósteum is closed. The operation has been performed on 47 patients; bony union has occurred in every instance except one.

Dr. **EVERETT O. JONES** and Dr. **H. T. BUCKNER** (Seattle) presented a paper on fractures of the pelvis. These fell into three main groups: fractures of the wing of the ilium, of the acetabulum, and of the pelvic ring. The authors of the paper said their practice was to put up fractures involving the acetabulum in a Whitman cast as for fracture of the neck of the femur. Fractures of the pelvic ring were treated in a double plastic spica for three months, except where there was upward displacement of one-half of the pelvis—when skeletal traction was applied to the femur—and in upward displacement with lateral spreading, caused by separation of the symphysis, in which a special method of suspension is used. Non-union of a pelvic bone was almost unknown, but failure of the symphysis to unite was very common, and a disrupted sacro-iliac articulation never became normal again. The paper was based on 40 personal cases, and the records of 312 cases. The mortality-rate (15 per cent.) was not high, but the final results were not "surprisingly good." In their series of cases 41 per cent. were left with some degree of disability ranging from 5 per cent. to total.

The Ear.

Dr. **ROBERT PULLEINE** (Adelaide), in a communication entitled An Insufficiently Considered Factor in Chronic Progressive Hardness of Hearing, said that snoring and blowing the nose, continued over a long period, resulted in gradual impairment of hearing. The primary cause was hereditary spur of the nasal septum, against which treatment should be directed. In the past this form of deafness had shared the bad prognosis of familial deafness, and has often been wrongly treated by routine inflation—the form of treatment most detrimental to it.

Dr. **FRANK A. PLUM** (Honolulu), summarising a paper on meningitis of otitic origin, said that delay was often caused by a diagnosis of meningism. Diagnosis must not wait upon appearance of a turbid fluid containing organisms, for the only chance of success depended on operation, which entailed removal of the focus of infection and drainage of the subarachnoid according to the route of infection. A careful bacteriological examination should be made of every mastoid operated on, and in pneumococcal and streptococcal infection the immediate use of serum was desirable. In diffuse cases, drainage, intracranial lavage, cerebral, cisternal and spinal, and Kolmer's intra-arterial medications are indicated.

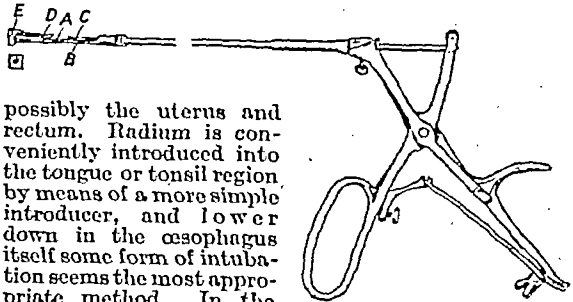
Dr. **A. T. WANAMAKER** (Seattle), in the course of an address on lateral sinus thrombosis, said that the Queckenstedt test was useful in diagnosing a mural clot, an obliterating clot, and narrow or absent lateral sinus on the non-infected side. A portion of the lateral sinus plate should be removed in all cases of mastoiditis with septic temperature. Experimental work on dogs had shown the value of not severing the jugular vein.

At the close of the Congress it was decided to hold a Pan-Pacific Surgical Conference at Honolulu every three years, the next to meet in 1932. Dr. George W. Swift was elected first President, Dr. Nils P. Larsen Vice-President, and Dr. F. J. Pinkerton Secretary.

New Inventions.

RADIUM-NEEDLE INTRODUCER.

I HAVE had constructed a radium-needle introducer for use in the less accessible parts of the pharynx (epiglottis, pyriform fossæ) and possibly the uterus and rectum. Radium is conveniently introduced into the tongue or tonsil region by means of a more simple introducer, and lower down in the œsophagus itself some form of intubation seems the most appropriate method. In the middle region of the lower pharynx, however, I have felt the need of an instrument which can be used through a direct laryngoscope, and the one shown in the illustration has proved slender enough for this purpose. Moreover, it affords a very accurate aim. The silk-threaded needle lies in the groove A in the shaft B, held down by a spring D and is propelled by a movable bar C through a countersunk opening in the square-ended, rough-surfaced foot-piece E which is held firmly on to the surface of the growth, all movements being slow and gentle to avoid damage to the silk thread.

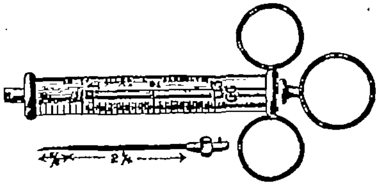


The instrument is made by Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, London, W.

DOUGLAS A. CROW, M.B., Ch.B. Edin.

A SYRINGE AND NEEDLE FOR THE INJECTION OF HÆMORRHOIDS.

HAVING adopted the treatment of internal hæmorrhoids by the high submucous injection of 5 per cent. phenol in vegetable oil, as described by Albright and Blanchard, I have had made a modification of the original Graeme Anderson outfit as shown in the illustration. The syringe holds 3 c.cm and is graduated in tenths of a c.cm. The valuable *bayonet fitting* for the needle is retained which permits immovable attachment of the needle to the syringe. The base of the needle is bored out as wide as possible and a No. 20 standard wire gauge stainless steel needle is now fitted. The total length of the needle has been increased to 3¼ in. The syringe and two needles are fitted into a small case as before. I find that the oily solution, even when cold, flows very readily through this needle with quite light pressure, and the high injection of the solution in adequate doses is rendered easy.

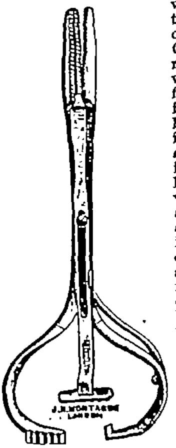


The instrument has been made for me by Messrs. *Allen and* Hanburys, Ltd., 48, Wigmore-street, London, W.

W. B. GABRIEL, M.S., M.B. Lond., F.R.C.S. Eng.

A PROSTATECTOMY INCISING CLAMP.

As is well known, after the actual enucleation of a prostate by Freyer's method a shelf often remains, which if not divided, may lead to partial or even complete occlusion of the vesical outlet. Cutting it with scissors may result in further hæmorrhage, while tearing it with the finger is not only crude but in some cases impossible. I have, therefore, designed the instrument shown in the accompanying illustration. It is about eight inches long, has an outer or handle portion with a self-releasing rack, and an inner portion consisting of a clamp and blade. The inner end for clamping and *cutting the shelf has flat* serrated jaws, each of which is deeply grooved down its centre. When the clamp has been applied the blade is pushed down the grooves to the end of the instrument. In this way the partition is not only divided but thoroughly crushed on each side of the incision, the process taking only a few seconds, and very much minimising the possibility of dangerous bleeding.



The instrument has been neatly and skilfully made for me by Mr. J. H. Montague, of New Bond-street, W.

W. K. IRWIN.

Reviews and Notices of Books.

INTERNAL SECRETIONS OF THE OVARY.

By A. S. PARKES, M.A. Cantab., Ph.D. Manch., D.Sc. Lond., Beit Memorial Research Fellow, Department of Physiology and Biochemistry, University College, London. London: Longmans, Green and Co. 1929. Pp. 241. 21s.

TEN years ago a book written upon the internal secretions of the ovary might have contained as much theoretical discussion, but it could only have included a fraction of the experimental facts which form the basis of Dr. Parkes's monograph. The rapid growth of the subject, to some of whose developments we recently called attention,[1] has not made his task any simpler, but has added greatly to his difficulties. It is easier to review the value of past discoveries than *to assess the importance of contemporary work*; there is always the possibility that some point at present apparently insignificant may suddenly become the centre of the picture. This possibility has recently been illustrated in the inter-relationship between the anterior pituitary and the ovary. As long ago as 1901 A. Fröhlich pointed out the connexion between pituitary disorders and aberration of sexual function, but it was not until 20 years later that the work of H. M. Evans provided a sound experimental foundation upon which B. Zondek and S. Aschheim in Germany, and P. E. Smith and E. T. Engle in America, have built up quite an imposing structure during the last three years. Their labours show that the anterior pituitary hormone, exercising influence on the gonads of both male and female, plays a much more important rôle than was previously supposed. *This is true of its effect on the ovaries* with which aspect of its activities the present volume is alone concerned, quite apart from the great part which the anterior lobe has been shown to play in promoting general bodily growth.

Dr. Parkes has well fulfilled his duties as a contemporary historian, and this in itself is an achievement. But he has done more than this. The value of his book is principally due to the fact that its author is himself in the vanguard of the small army of workers who are actively engaged in research upon these problems, and has thus been able to exercise a wise discrimination in the selection of his subject matter. There are few statements in this book that cannot be proved by direct experiments. Theoretical considerations receive adequate consideration, but Dr. Parkes has them well under control. Essential arguments are stated briefly but clearly, and at each stage the experimental evidence in their support is critically surveyed.

The book starts with a brief account of the morphology of the glands, the reader being referred for a detailed description to special anatomical and histological treatises. A fairly exhaustive survey follows of sexual periodicity and types of œstral cycle in those species of the female mammal in which it has been sufficiently well investigated. This *section is well illustrated, and will be found valuable*, particularly by those who are themselves carrying out experimental work in this subject. The ovary as an organ of internal secretion is then considered generally, in a section which forms an introduction to the more detailed one dealing with the œstrus-producing hormone. This latter occupies some fifty pages of the book and is the best account of this subject available at the present time. No important contribution seems to have been omitted and all are clearly presented as part of a coherent whole—an entirely successful conclusion to what must have been an exceedingly intricate piece of work.

The final sections of the book deal first with the anterior pituitary body and then with the corpus luteum, considered in their relation to the ovary and its function. Both these sections are well done, and the literature here, as elsewhere, is complete up to the end of last year. The final chapter on parturition will be of very general interest. For the selection of the bibliography of some 650 references we have nothing but praise, but this most valuable collection would have been made even more useful if the numbers of the page as well as the year and volume of the various journals had been included. The book is admirably produced and is illustrated by more than fifty excellently chosen photographs.

---

SURGERY.

Beiträge zur praktischen Chirurgie. By Dr. ALBERT KRECKE. Munich: J. F. Lehmanns. 1929. Pp. 1094. M.12.

THESE reports from Dr. Krecke's private surgical clinic for the years 1923 to 1926 inclusive are well worth reading. The 18 sections deal with almost every branch of general surgery, and many of them make very interesting reading. The author makes no startling new suggestions but he describes clearly his methods of dealing with everyday surgical problems. He reviews critically the results of different treatments and his deductions seem to be based upon sound logic. A valuable feature is an analysis of his failures, which are faithfully described without excuse or extenuation. The reader may not agree with all the author's recommendations and ideas on different surgical problems, but will inevitably ponder these views and consider whether his own need revision. Much that is here written is mere commonplace routine surgery; yet the records are worth the attention of any surgeon, for there are sure to be interspersed here and there interesting clinical facts of which he is unaware.

MOVABLE KIDNEY.

Second edition. By WILLIAM BILLINGTON, M.S., Ch.M., F.R.C.S., Senior Surgeon, Queen's Hospital, Birmingham; Professor of Surgery, University of Birmingham. London: Cassell and Co., Ltd. Pp. 177. 12*s.* 6*d.*

IT is 19 years since the publication of the first edition of this monograph. When it appeared the subject of movable kidney occupied much attention both in this country and abroad, but since then nearly every surgical observer has become convinced that nephropexy is an operation seldom required. Perhaps the pendulum has swung too far in the direction of abstention. Mr. Billington obviously thinks so, for he says "movable kidney may be responsible for seriously lowered efficiency of mind and body and for widespread and persistent functional disturbance." This is a conclusion reached after an experience of operations upon upwards of 1500 patients. The reader may reasonably inquire what increase of surgical knowledge has accrued from this unusual experience of a single operation. He must judge by reading this book. It contains some stimulating suggestions, as when the author attributes the symptoms of movable kidney to imbalance of the sympathetic and parasympathetic systems. "Chronic recurrent over-stimulation of the nervous mechanism whether from constant tugging as in movable kidney, or chemical as in retained products of excretion, produces permanent changes in the nerves and ganglia." Such an explicit statement seems to require some supporting evidence which is not here offered. The author does, however, say definitely that the urine in movable kidney often contains albumin, which disappears after the fixation of the kidneys. A valuable observation is that a large proportion of movable kidneys show some structural change. In the diagnosis of this condition it appears to be a little difficult from objective signs to say when a degree of mobility is abnormal. A pyelographic examination is surely of more importance than Prof. Billington is willing to concede. It does at least show when dilatation is occurring, with consequent changes in the renal substance. Such conditions are really signs of hydronephrosis and not only of simple renal mobility. "A growth of the colon may be easily mistaken for a movable kidney and vice versa," says Prof. Billington; but the symptoms and signs are so different that this must surely be an unusual mistake.

In order to get a true estimate of results the author asked an independent physician to investigate 163 of his 1500 cases. There was "complete success" or "success" in 43 per cent. and improvement in 25 per cent. of this group. The evidence offered is invalidated by the fact that "by far the greater number which constituted groups 1 and 2" (that is "complete success" and "success") "have had appendicectomy as well as kidney fixation." The author does well to emphasise the fact that the operation has no moral value. Indeed he regards it as a further strain upon a mind and body already over-stimulated and exhausted. The last word on this surgical problem has not yet been said.

ON NEPHRITIS.

By A. CECIL ALPORT, M.D. Edin., M.R.C.P. Lond., Assistant to the Director of the Clinical Medical Unit, St. Mary's Hospital, London. With an introduction by Prof. FREDERICK LANGMEAD, M.D., F.R.C.P., Director of the Unit. London: William Heinemann (Medical Books), Ltd. 1929. Pp. 175. 7*s.* 6*d.*

THE student will be somewhat disappointed in this book, after reading the excellent introduction by Prof. Langmead, for Dr. Alport in surveying the inflammation and degeneration of the kidney does not succeed in elucidating the confusion which surrounds their classification. From Chapter VI., dealing with the Degenerative Group or Nephrosis, no very clear conception of what the term "nephrosis" connotes is obtained, and the author makes no mention of the absence of all cardiovascular change in this condition. This is a grave omission, and in the chapter dealing with Subacute Parenchymatous Nephritis Dr. Alport fails to point out the essential distinction between cases of albuminuria and œdema with cardiovascular change and those in which such change is absent. The failure would be more understandable if these chapters were not enlarged by the inclusion of copious references to recent literature. In the chapter dealing with Chronic Interstitial Nephritis it is hard to reconcile the inclusion of many recent references with the omission of all reference to the classical work of Gull and Sutton, who many years ago laid down accurately the pathology of the majority of cases included in this book. The chapters devoted to biochemistry are not up to a standard which would be favourably received by expert laboratory workers; for example, the description of methods for the estimation of the nitrogenous constituents of the blood contain no reference to the classical methods of Folin and Wu. We are well aware of the difficulties surrounding the subject, but hold that the exposition of modern ideas of classification is only profitable if the essential differences between the old and the new conceptions are made clear.

Dr. Alport's survey contains much interesting material, but he has not given a clear picture of nephritis as distinct from nephrosis.

DIETETICS.

Chemistry of Food and Nutrition. Third edition. By HENRY C. SHERMAN, Ph.D., Sc.D. Mitchell Professor of Chemistry, Columbia University. London: Macmillan and Co., Ltd. Pp. xii. + 636. 12*s.* 6*d.*

The progress of the science of nutrition in recent years has necessitated the frequent revision of textbooks. Prof. Sherman's book has been almost completely rewritten and now includes several new chapters as well as considerable additions to the valuable lists of references which are appended to each chapter. This work is not a treatise dealing merely with the chemical composition of food and the mode of utilisation of foodstuffs in the animal body, but is a clear and connected account of the physiological principles concerned in the normal nutrition of mankind. It is intended primarily for those who are making a special study of nutrition, although it can be recommended also for those who are interested in a more general way in modern conceptions of the relation between diet and health. As an illustration of the difficulty of keeping a text-book up to date it may be noted that no mention is made of ergosterol as the precursor of the antirachitic vitamin, and the water-soluble vitamin B complex is still dealt with as a single entity.

A Laboratory Handbook for Dietetics. Third edition. By MARY SWARTZ ROSE, Ph.D., Professor of Nutrition, Teachers College, Columbia University. Same publishers. 1929. Pp. 269. 12*s.* 6*d.*

A handbook written by Prof. Mary Swartz Rose consists essentially of tables indicating the average chemical constitution of common foods in respect of well recognized constituents such as protein, fat, carbohydrate, calcium, phosphorus, and iron. The tables are preceded by instructions on how to use them to devise diets containing the required amounts of any of these constituents, together with the requisite energy values. The tables are designed so that all unnecessary calculations can be avoided, hence the amounts of the various food constituents are given not merely as a percentage of the raw or cooked food, but as the actual amount present in one gramme, one ounce, one pound, and one portion furnishing 100 calories of energy. The book has already proved of value to those engaged in constructing diets either for individual hospital patients or for healthy inmates of institutions. It should not be forgotten, in using a reference book of this kind, that even the most elaborate calculations of the dietetic needs of an individual are liable to many sources of error. In the first place the interpretation of the results of chemical analyses is not always a simple matter. For example, recent work done in this country on the carbohydrate content of fruits and vegetables makes it clear that considerably larger amounts of such foods may often be allowed to diabetic patients than would be calculated from the food analysis tables included here. Again, it is assumed in certain of the tables that we have a working knowledge of man's daily average requirements of mineral salts such as calcium, iron, and phosphorus. But on the contrary the body's needs for these substances vary enormously with other factors in the diet or environment, and it is clear that the giving of an accurately calculated quantity of each mineral element may not itself necessarily secure the desired physiological result. These criticisms do not affect the main usefulness of the book, which will enable diets of any particular character to be designed with the minimum amount of labour.

CHEMISTRY AND BACTERIOLOGY OF PUBLIC HEALTH.

By C. L. DUNN, C.I.E., D.P.H. Lond., Director of Public Health, United Provinces of Agra and Oudh; and D. D. PANDYA, D.P.H. Camb., Professor of State Medicine, University of Lucknow. Calcutta: Butterworth and Co. (India), Ltd. 1929. Pp. 412. 12*s.* 6*d.*

THIS is a publication primarily intended for students in India who are preparing for the Part I. Course of the Diploma in Public Health, and is a companion volume to an earlier work by the same authors entitled "Indian Hygiene and Public Health." Its scope is a wide one, embracing public health chemistry, bacteriology, and parasitology, and in the small compass of some 400 pages the student will find that most of the essential subject matter has been dealt with.

In the chemical section the practical tests are well chosen. A valuable section is that devoted to Indian milk products and substitutes. There is only a brief reference to British regulations for preservatives in foods, or to methods of estimation, and no mention is made of Royal Commission Standards for Sewage Effluents, or of the theory of action of natural waters upon lead. The small quantities recommended for some tests for water and the high dilutions for its bacteriological examination are no doubt connected with the low degree of purity commonly found in Indian water-supplies. Details of technique are not always correct, and this applies both to chemical and bacteriological sections. For example, phenolphthalein is recommended in the standardisation of sulphuric acid with sodium carbonate, and, again, methyl orange for acidity of waters, ignoring carbonic acid. In Winkler's method for dissolved oxygen a serious error would be introduced by the exposure in pouring before acidification; and it is stated that all vegetable oils have a clarifying temperature (Valenta test) above 80° C., and that the silver nitrate precipitate with CO_2 is insoluble in nitric acid.

In the bacteriological section, also, there are several misleading statements. For instance, the spore *B. anthracis* is contrasted with that of *B. tetani*, and only the former is termed an endospore. Such misstatements as those made on p. 249, giving the temperature range for cultures of *B. typhosus* as 40° C. to 46° C., and on p. 261, where for preventive inoculation a dose of "500 to 1000 units of *toxin* is advised," require correction. The discussion of agglutination in diagnosis is inadequate; such important points as the inhibition zone, variation in the agglutinability of suspensions, and delay in the appearance of agglutinins are not mentioned. In the description of typhoid agglutinations the series of diagnostic titres given show that the authors do not appreciate Dreyer's method, although they give it in detail. References to food poisoning and other pathogenic organisms in food, and to methods of isolation, are too brief. Four chapters are devoted to spirochæta, protozoa, animal parasites and hosts, and these contain much useful information, with classification of these organisms, and a detailed study of mosquitoes. The work suffers from the lack of illustrations which are really necessary for the study of all branches of hygiene.

It will be clear that the work can only be recommended as a text-book, where it is supplemented by practical laboratory instruction under capable teachers, so that defects in the descriptions and in the technique prescribed may be corrected verbally.

TUBERCULOSIS.

Laboratory Diagnosis and Experimental Methods in Tuberculosis. By HENRY STUART WILLIS, The Johns Hopkins University and Hospital. London: Baillière, Tindall and Cox. Pp. 330. 16*s.*

THIS is primarily a book on the laboratory diagnosis of tuberculosis, but since it is written from a very wide angle the reader is given a good understanding of the rationale of the methods adopted. Furthermore, Dr Willis has been generous in his interpretation of the term laboratory diagnosis, so that much information is included, notably in Part 3, on tuberculin, which is not supplied in ordinary laboratory text-books. The book is divided into five sections. The first gives a general description of the various secretions and excretions which must be examined in the study of tuberculosis. The second deals with bacteriological diagnosis and includes the well-known staining reactions for the tubercle bacillus, concentration methods, animal inoculation, culture media, and so forth. It also contains two chapters worthy of special comment. One forms a useful summary of the three main types of tubercle bacilli with their characteristics and includes a suggestive section on the probable basis of acid fastness; the other is concerned with the non-pathogenic acid-fast bacteria, which are too often tactfully ignored in laboratory manuals. The third part of the book is devoted to tuberculin, its preparation and its diagnostic application to tuberculosis. A welcome chapter describes the standardisation of tuberculin. The fourth part is devoted to the serological diagnosis of tuberculosis, and here a full description is given of the tuberculo-complement-fixation test. The other serological tests are described very briefly, rather less than four pages being devoted to them all, including the sedimentation-rate test. The reason that the author has not considered it worth while to give more space to their consideration is clear from his comment that, although certain of these tests are of value in prognosis, none is dependable for diagnosis. Perhaps nothing more damning could be said about them. The fifth part deals with histological technique; the whole process is traced from the technique of handling and fixing tissues to the various staining methods, and the types of stains suitable for different tissues are described. This part of the book also includes a careful account of the methods of animal inoculation for tuberculosis, together with a description of experimental tuberculosis as induced in various animals.

Numerous diagrams and illustrations of laboratory apparatus add to the value of this work, which supplies an equipment list for a tuberculosis laboratory compiled from the inventory of the laboratory of the Kenneth Dows Tuberculosis Research Fund. An adequate bibliography is appended.

THE ESSENTIALS OF HISTOLOGY.

Twelfth edition. By Sir EDWARD SHARPEY SCHAFER, F.R.S., Professor of Physiology at the University of Edinburgh. With the coöperation of H. M. CARLETON, Ph.D., Lecturer in Histology in the University of Oxford. London: Longmans, Green and Co. 1929. Pp. 628. 15*s*.

THIS most familiar of medical school text-books has again been exhaustively revised and brought up to date. Practically every section has received detailed attention in the process. The section on blood has been recast and much extended, and the appendix on histological methods thoroughly modernised. Many excellent new illustrations have been added, while few of the old ones have been discarded, so that the book is even more liberally illustrated than ever. Indeed, this liberality is carried almost to a danger-point, in that the authors have permitted the retention of some of the old figures which are hardly up to modern standards of photomicrography, and fall notably below the general high standard of the book as a whole.

One point arises out of the teaching matter, and this touches the question of the identity of the "proximal" renal tubule. Schafer remains a steadfast supporter of the claims of the second convoluted tubule to the title, while a large body of teachers now favour the first convoluted tubule. This is one of the questions which medicine has so far failed to solve.

DENTAL ANATOMY.

A Graphic Presentation of Tooth Forms with an Original Technique for their Reproduction. By M. DIAMOND, D.D.S. Associate Professor of Dentistry, Columbia University Dental School. New York: Macmillan Company. 1929. Pp. 300. 21*s*.

IN America the investigation of tooth forms has been developed in considerable detail, and the training of the student in many dental schools comprises the reproduction of the teeth in wax or other material. This book provides a detailed study of the naked-eye anatomy of the teeth which corresponds to the descriptions in text-books on osteology of every mark on the skeletal bones. There is no doubt that the macroscopic anatomy of the teeth is important, and that the dentist should be thoroughly familiar with the normal structure of the organs which he has to repair or closely to imitate. A book devoted to the subject can scarcely make light reading, and must be used as a laboratory manual rather than a text-book for systematic study. If it is used in conjunction with laboratory exercises in the carving of tooth forms it should prove useful. Presumably it was designed for this purpose, since considerable space is allotted to precise instructions for carving teeth out of blocks of wax. In view of the detailed descriptions of every cusp and fissure on each tooth, it is surprising that the author does not deal fully with the deciduous teeth other than the first deciduous molar. The idea that the deciduous teeth are only a replica in miniature of the permanent ones is widespread, but in many points their anatomy differs, and the five pages devoted to the deciduous dentition are inadequate. The value of conservative treatment of the deciduous tooth is now firmly established, and a detailed knowledge of their anatomy is therefore necessary. We trust that this defect in a useful book will be remedied in future editions.

INFANT WELFARE.

The Infant and Young Child. Second edition. By JOHN LOVETT MORSE, A.M., M.D., EDWIN T. WYMAN, M.D., and LEWIS WEBB HILL, M.D. London and Philadelphia: W. B. Saunders Company, 1929. Pp. 220. 9*s*.

THE intelligent public now demands authoritative and up-to-date information about its health and more especially about the health of its children. This book, by three well-known members of the staff of Harvard Medical School, should be popular, for it is well written, up to date, and thoroughly sound. In this new edition the sections on rickets and ultraviolet light have especially been revised and rewritten because in the authors' opinion there exists a great deal of misinformation about these subjects. New sections have been included on whole milk modifications, green vegetables, poor appetite, and sunshine. In many details the book is excellent and the authors are to be congratulated on their courage in including a small but wise section on the religious education of children.

OUTLINES OF ZOOLOGY.

Eighth edition. By J. ARTHUR THOMSON, M.A., M.D., Regius Professor of Natural History in the University of Aberdeen. London: Humphrey Milford, Oxford University Press. 1929. Pp. 972. 21*s*.

THIS excellent manual for students of zoology has now reached its eighth edition. Numerous original figures have been added, more account has been taken of the physiological aspect of the subject, and more space has been devoted to the structure and development of certain types, such as the Mud-fishes. As a manual for the zoology lecture-room, museum, and laboratory this book has a deservedly high reputation.

The medical and veterinary student will find the chapter on physiology valuable as a preparatory study for his future work. The chapters on morphology and embryology are presented in a readable style. Throughout the book the author links up general with medical zoology. He gives clear accounts of the malaria parasites, the coccidia, trypanosomes, and disease vectors. The details of the process of rumination (page 581) might have been given a little more precisely. We are told (page 220) that "the young fluke makes its way up the bile-duct and its tributaries" to the liver, whereas in fact it burrows its way through the bowel wall and penetrates Glisson's capsule to reach the liver parenchyma. It is this fact which makes the disease so disastrous.

In some places the nomenclature used is not up to date; for example, *Distomum hepaticum* is now generally called *Fasciola hepatica*, and *Eustrongylus* becomes *Dioctophyme*. The volume is well bound, clearly printed, and profusely illustrated.

THE LANCET.

LONDON: SATURDAY, DECEMBER 28, 1929.

AIR-BORNE INFECTION IN PUERPERAL SEPSIS.

In the early days of the antiseptic theories air-borne infection as a factor in the causation of wound infections was given a prominent place; however, it gradually receded into the background and for a time was discarded, though not as whole-heartedly as the carbolic spray designed to counteract its dangers. The possibility that pathogenic organisms might reach the wound surfaces from the air was not entirely banished from the minds of surgeons, and thus, after a long interval, the face-mask was introduced and generally adopted at operations in order to lessen the risk of spray infections from the mouth and respiratory passages of the persons surrounding the patient. The adoption of a mask during the dressing of wounds and attendance on maternity cases has never become general, but in a recent paper on Air-borne Infection in Puerperal Sepsis[1] Dr. Richard Armstrong brings us back to the original Listerian position, and, since the evidence produced is convincing, a wider use of the mask by accoucheurs and nurses should be encouraged. Dr. Armstrong's paper gives clinical data and a scientific basis for air-borne wound infections, and describes three epidemics of puerperal sepsis in two of which full bacteriological examinations were made of patients and their attendants. One of these epidemics took place some years before the other two, and no bacteriological investigations were made, but there was strong evidence that the resident medical officer was a carrier of *Streptococcus pyogenes.* The hospital records showed not only a higher incidence of morbidity during his term of office than in those of his predecessor and successor, but also a lull in the epidemic during his absence on holiday. He had a hæmatoma which suppurated, although the overlying tissues were intact, and, after his hospital appointment was over, developed erysipelas after a facial injury—both strong indications that he was a carrier. Besides these three outbreaks of puerperal infection, a smaller one of erysipelas in a surgical ward was studied by Dr. Armstrong. Here the epidemic was traced to staff nurses responsible for the dressing of wounds, who were found to have streptococcal throat infections.

Dr. Armstrong quotes other spray infections such as the one in the Aberdeen Maternity Hospital described in the ten-year maternal mortality investigation made by Dr. Parlane Kinloch; and the epidemic of puerperal fever in the Sloane Hospital, New York, recorded by Watson and others, both of which support his thesis. From consideration of these, from observation of the origin and spread of other infections, and from animal experiments, he draws the conclusion that the rate of spread in air-borne sepsis is by geometric progression; each carrier infects several persons, and each of these a corresponding number, so that once infection is introduced into a maternity ward, all in it, mothers and attendants alike, become liable to harbour the organism though the maternal placental site is the most susceptible. On admission into an area in which the density of infection is already high, each batch of later and susceptible entrants meets also the increased bacterial virulence that is likely to follow the passage of infection from case to case, and hence the disease tends to assume a more serious form. There appears to be a period of three to five days between infection and the appearance of symptoms, and this incubation period is taken to represent the *passage upwards from vulva to uterine cavity,* probably by the suction of diaphragmatic respiratory movements. Since attendants and patients may both be infected by carriers and yet show no clinical signs of illness, prevention and detection of an air-borne epidemic in its earliest stages may not be easy, but Dr. Armstrong has established a case for special precautions in maternity hospitals and wards. Prevention by the investigation and exclusion of all with sore-throats or other suggestive symptoms, by the wearing of face-masks, and by the early detection and isolation of both patients and attendants in order to lessen spread and the effects of heightened virulence, are clearly necessary precautions, and point to the need of a pathologist with adequate laboratory facilities attached to all institutions which provide maternity beds.

Precautions against air-borne infections must not, however, be allowed to dominate the situation, for, by themselves, they will not succeed in effecting a substantial reduction in the incidence of puerperal sepsis. Dr. Armstrong draws attention to the greater mortality risk in streptococcal infections arising from operative interference and trauma, and quotes the result of a study of 2000 cases delivered in the extern *maternity district of St. Bartholomew's Hospital* where the morbidity-rate amongst the forceps deliveries was found to be increased tenfold. The introduction of infection during parturition is still the most important factor in the production of sepsis, and the avoidance of operative interference and trauma is the measure that will diminish the mortality from puerperal fever.

GOOD FAITH AND REASONABLE CARE.

The Court of Appeal has given an important decision in an action brought against two medical practitioners by a patient whom they had certified under the Lunacy Act. Not only is the decision significant in view of the attempt in Clause 16 of the Mental Treatment Bill to strengthen the protection afforded to the medical profession by Section 330 of the Act of 1890; it is also valuable as evidence of a welcome tendency on the part of His Majesty's judges to interpret the existing law in such a manner as not to deprive the doctor of a useful first line of defence. As the profession well knows, Section 330 declares that a doctor who takes any step in the certification of a lunatic is not to be liable to any civil or criminal proceedings if he has "acted in good faith and with reasonable care." The Section goes on to enact that proceedings may be stayed by the High Court or a Judge thereof if the Court or Judge is "satisfied that there is no reasonable ground for alleging want of good faith or reasonable care." It has never been an easy matter to obtain the aid of the Court under this latter provision. Judges are conscious that they must protect the liberty of the subject and must not lightly intervene between a plaintiff and a jury. The Court of Appeal's recent intervention is the more notable because of the terms used by Lord Justice Scrutton in expressing it.

---

[1] St. Bartholomew's Hospital Reports, vol. lxii., p. 169.

Mrs. JANE EASTON, of Lancaster-gate, brought an action against Dr. WILLIAM ALEXANDER POTTS, of Edgbaston, and Dr. A. V. JOHNSON, of Aldridge, claiming damages for alleged negligence on their part in certifying her in 1926. The defendant doctors applied to have the action stayed on the ground that they had acted in good faith and with reasonable care. The Master, before whom the application first came in Chambers, was satisfied of their good faith but did not feel able to say that there was no evidence of a failure to use reasonable care. Mr. Justice FINLAY agreed with the Master. The Court of Appeal has reversed this view and has ruled that the defendants acted with reasonable care and that there was no evidence on which a jury could reasonably find to the contrary. Mrs. EASTON, at the material date, was on a visit to Staffordshire. The friend with whom she was staying took a serious view of her condition and sent for her sister. The sister agreeing, a doctor was called in. One of the first two doctors refused to certify; next day Dr. POTTS and Dr. JOHNSON certified Mrs. EASTON and she was sent to an institution for treatment. Evidence of her mental state can be gathered from the Lord Justice's judgment. She was, it seems, between 48½ and 50 years old. She had suffered from malaria and she admitted she was in a very depressed condition. A belief in hypnotism, telepathy or thought transference is, as the Court observed, no proof of insanity. This patient, however, seems to have had the delusion that people could, by hypnotic influence, have carnal intercourse without touching each other, and that a doctor whom she saw for the first time had in this spiritual fashion criminally assaulted her in London some years earlier. If a woman thought this, said Lord Justice SCRUTTON, no reasonable jury ought to find that she was not reasonably certified. He was also impressed by her belief that everybody had a sort of aura of smell; she had apparently told the doctor that she smelt him through the door; her letters and postcards, too, though the certifying doctors had not seen them at the time, would have been significant evidence to put before a jury.

Protection offered by Section 330 of the Lunacy Act has thus for once proved not less substantial than the medical profession originally believed it to be. There should, however, be no relaxation of the endeavours to obtain a further strengthening of it in the Mental Treatment Bill. The proposed new Clause seeks this object by throwing upon the plaintiff the burden of proving that the certifying doctor acted in bad faith or without reasonable care. Although English law has always insisted that this burden must be discharged by the plaintiff as a general principle, Section 330 of the Lunacy Act is so drafted as to suggest that the defendant doctor cannot avail himself of the statutory protection unless he positively proves his own good faith and reasonable care. The proposed amendment falls a long way short of the security to which the medical profession is entitled, but, for what it is worth it is a welcome instalment. Lord Justice SCRUTTON emphasised the importance of protecting those who, at the invitation of Parliament, fulfil a duty in the interests of the community as well as of the patient. "If any doctor certifying is to be exposed to the cost and danger arising after the event of judgment (by people who did not see the patient at the time) that the patient at that time was not of unsound mind, the only effect and the natural effect would be that no doctor would certify, and that the community, which is to be protected as well as the individual, would be exposed to the risk of having persons of unsound mind wandering about without adequate control to the danger of themselves and possibly to the danger of the community. We have had a series of cases in recent years showing the risks to which doctors are exposed by actions alleging that they have certified improperly either dishonestly or without due care. It is common knowledge that the result of these cases has been that many doctors will not certify at all. They would not run the risk of undertaking the duty Parliament seeks to put upon them." Other judges have used similar language, and Parliament should take note of the warning.

It is, of course, a difficult matter for one judge to say that there is no possible case for a jury when another judge has taken a different view. This difficulty was remarked by Lord Justice VAUGHAN WILLIAMS in 1913, when the Court of Appeal similarly overruled Mr. Justice ROWLATT in Shackleton *v.* Swift. But in the present case Mr. Justice FINLAY relied upon the affidavit of Dr. RISIEN RUSSELL, and Lord Justice SCRUTTON patently did not. Remarking that he intended no reflection upon Dr. RUSSELL in describing him as usually the principal witness for the plaintiff in lunacy cases, the Lord Justice observed that Dr. RUSSELL'S affidavit said nothing whatever about Mrs. EASTON'S case. Dr. RUSSELL had not seen her; he did not say he had seen the other doctor's affidavits; he said in general terms that a thorough physical and mental examination should always be made before certifying in a case of suspected insanity; he detailed an elaborate system of tests which he said should be applied. But, said Lord Justice SCRUTTON, a doctor coming to examine a patient in this way is not employed by the patient, and has no authority to conduct these detailed operations to all of which the patient would strenuously object. On this same point Lord Justice GREER added that if it were intended to lay down a general rule that no medical man can safely sign a certificate without carrying out all these tests enumerated in Dr. RUSSELL'S affidavit, "then I have no hesitation in saying that the affidavit ought not to be accepted by any court which knows anything about the matter." It was ridiculous, he continued, to suppose that a doctor could not without all those tests under any circumstances certify that a person should be placed under control. This common-sense and highly authoritative ruling may act as a corrective which has long been wanted.

CLINICAL RESULTS WITH ŒSTRIN.

THE progress made during the last few years in the study of the hormones of the ovary has recently been described in our columns. A longer survey made by Dr. A. S. PARKES is reviewed on p. 1367 of this issue of THE LANCET. The reason for the rapid advance is the development of methods of biological assay on the one hand, and of preparation and purification on the other, until at the present time it is possible to prepare very potent extracts from ovaries and placenta. To these sources must now be added the urine of pregnant women, a particularly rich source of the hormone. Not all material from these sources is active and it is therefore of the utmost importance that all clinical trials with these extracts of the ovary and placenta should be carried out upon biologically standardised preparations. The most definite and certain property of these extracts is their action upon the ovariectomised animal, particularly the mouse and rat, discovered by ALLEN and DOISY a few years ago. To ascertain whether any particular extract is active and to determine its potency, it is only necessary to observe whether it will restore the sexual cycle in the ovariectomised animal and to discover what dose is necessary to bring about this result. The discredit attached to ovarian therapy in the past was due to ignorance of a reliable method of testing the activity of the preparations employed. Whether the use of standardised preparations will restore faith in this method of treatment depends on clinical results, which are not easy to assess. Mr. WILFRID SHAW[1] in this country and Dr. E. L. SEVRINGHAM and Dr. J. S. EVANS[2] in America have been trying respectively the oily and water-soluble preparations on a group of cases and have published their experiences which are encouraging though not conclusive. This is not surprising, for there is little analogy between the œstrus of the laboratory rodents, coincident as it is with the period of sexual activity, and menstruation in man and the higher primates; the difference is held to be connected at least in part with the functions of the corpus luteum. It is clear that in those patients in whom the deficiency, whilst it may be hormonal, is not primarily one of the œstrus-producing hormone of the ovary no effect can be anticipated. Moreover, the problem of dosage is not yet solved. If the correct dose is proportional to the body-weight, a woman with complete ovarian deficiency will require a dose of some 1500 rat units, an almost impracticable quantity. With the small doses available at present too much must not be expected. The distribution of the dose, however, can be controlled. The preparations used are of two kinds: oily and water-soluble. The earlier oily preparations suffer from the disadvantage that they are liable to give pain on injection, and SHAW refers to the severity of the local reaction produced. The fact that they are slowly absorbed, however, may be an advantage, since the effect of the dose is spread over an appreciable time. In animals a single injection of the aqueous preparation is much less effective than that of the same total amount of material given at frequent intervals. Aqueous preparations such as those used by SEVRINGHAM and EVANS are not followed by any local reaction, but they have to be given frequently, probably daily, to get the best results.

The hysterical tendencies associated with some of the conditions studied tend to increase the difficulties of the clinical work. In view of the fact that one of the most striking properties of œstrin is its action in promoting uterine growth in experimental animals Mr. SHAW examined the effect of the hormone in 15 cases of spasmodic dysmenorrhœa, with the typical ill-developed uterus associated with this condition. In six of these no improvement was observed, even when 50 units were given at weekly intervals; all were severe cases. In nine others the treatment was successful either in completely freeing the patients from pain or in alleviating it. The size of the uterus, however was increased only in two cases and in all the symptoms returned when the injections were stopped. The author recommends trial of the treatment in young women and where dilatation of the cervix is not successful. Not all cases respond, and if after eight weeks there is no improvement the injections should be discontinued. In five cases of primary amenorrhœa no definite effect was observed and menstruation was not established in any of the subjects. Two cases of amenorrhœa of secondary type also gave negative results. Both of these were combined with adiposity, and in each of six further patients who were not adipose menstruation followed the administration of œstrin. The results indicate that the treatment may be of value when the symptoms are of recent date. Other cases in which good results have been observed include women with irregular menstrual periods. According to SEVRINGHAM and EVANS, relief is also given in menopausal disturbances, particularly those associated with vasomotor phenomena, in which good results are reported in 10 or 11 out of 15 cases treated. Both the English and American investigators refer to the handicap of the lack of an objective index of ovarian activity in the human subject, a circumstance which together with the spontaneous improvement well known to occur in young patients, makes the scientific evaluation of any drug extremely difficult. The workers themselves consider the results obtained to be in many ways encouraging.

Annotations.

"Ne quid nimis."

HOSPITAL ASSESSMENT.

WHY is it that the attempt to lighten the burden of rates borne by the voluntary hospitals has achieved so little success? The hope of total de-rating has been frustrated because it spoilt the symmetry of recent enactments framed by reformers who forgot the hospitals. The Central Valuation Committee's advisory functions have failed to achieve the uniformity in valuation which it is that body's statutory duty to promote. The Committee most helpfully suggested an equitable basis for assessing hospitals; it would have meant an advantage only less valuable than total de-rating; but the suggestion has been largely ignored and the utmost diversity of practice flourishes. The hospitals' prospect of swollen demands for rates is deplorable. The recent report on the Voluntary Hospitals in Great Britain[1] (excluding London) contains a memorandum on the present situation which makes gloomy reading. The revision of assessments consequent upon the Rating and Valuation Act of 1925 means that the provincial voluntary hospitals in England and Wales will have to pay £66,000 annually in rates where formerly they paid £44,000. It is a crushing imposition, unjust in its haphazard and anomalous incidence. Stated in terms of assessment per patient bed, the amounts vary from nothing at all in one place to £20 in another. Only 19 per cent. of the new assessments are less than £1 per patient bed; more than 12 per cent. are £5 and over. The British Hospitals Association has done its best. It has tried to obtain general support for a uniform and preferential assessment which would not exceed £1 per patient bed, such assessment to cover all those parts of the hospital that are necessary to enable it to carry out the purpose for which it is established. Unanimity in support of this reasonable proposal has been lacking. Many hospitals are willing to uphold it; a few favour independent action and other remedies. Meanwhile the financial prospect is uncertain and dark. Some local authorities are making contributions under the Public Health Act—that is to say, they take with one hand and give back with the other; this process may be satisfactory locally but it does nothing to solve the problem as a whole. If hospitals elsewhere have a greatly increased bill for rates, is the deficit to be met by a contraction of the hospital's facilities or by begging from generous donors whose charitable donations may be diminished in view of impending new taxation? There is general sympathy for the voluntary hospitals; nobody wants to see them unfairly harassed. Cannot some sensible formula be framed which will give them equitable treatment and which can be submitted to the valuation authorities with unanimous support?

THE BLOOD COUNT IN RHEUMATIC FEVER.

IT has long been recognised that rheumatic fever in children is associated with a mild leucocytosis, and the work of Swift and his collaborators[2] seemed to show that its degree bears some rough relationship to the severity of the joint manifestations. Could such a relationship be demonstrated in cases where infection falls rather on the heart muscle than on the joints, it might help us in gauging cardiac damage and the response to treatment. This possibility has recently been investigated by Dr. C. Bruce Perry,[3] working in the University Centre of Cardiac Research, Bristol. He finds that some degree of leucocytosis is common to all cases of rheumatic fever, whether the predominant feature is arthritis, carditis, or chorea. The presence of eosinophilia—which has been described as characteristic of the condition—is, he notes, associated with subsidence of the acute symptoms, and with the relative lymphocytosis which is seen when many kinds of infection are subsiding. As in most other infections, the increase of white cells in the more acute stage mainly affects the neutrophiles. The subacute and smouldering cases of carditis show only a slight and varying leucocytic response, and since it is just in these cases that an indication of the activity of the infection is most needed, Dr. Perry concludes that the leucocyte count can give us little or no assistance in measuring the progress of this disease.

X RAY APPARATUS.

To realise how rapid has been the growth and development of the X ray industry one had only to compare the exhibits at the recent annual meeting of the British Institute of Radiology with those of former years. High tension installations, radiographic and therapeutic equipment formed the three main groups of apparatus shown, and in each group there was a welcome tendency to simplification and standardisation in design. The X ray transformer has become more and more popular. The advantages of economy and freedom from contact troubles, associated with the inductive devices for the control of transformers, have no doubt led many to adopt the transformer instead of the resistance-controlled coil unit. With the erection of the grid system for the supply of alternating current to large areas, the use of the X ray transformer to the exclusion of direct current instruments would appear almost inevitable. It seems that the rating of a transformer in kilo-volt ampere hours is still widely used, although this unit is inadequate for the special requirements of radiology, and a specification for the electrical performance of transformers for X ray purposes was issued more than a year ago by the British Electrical Standards Association. General acceptance of this specification by manufacturers would materially help the buyer of high tension equipment. As a means of rectifying the current from a transformer the mechanical rectifier is fast disappearing. The majority of the transformer units of to-day are fitted with valves, the noiseless rectification of which appeals to the radiologist. Accumulated experience in the manufacture of valves has led to the production of a rectifier which, though expensive, is generally claimed to have a long life. The insertion of high tension condensers in the secondary circuits of transformers is quite common especially in deep therapy units. By means of condensers and an ingenious switch-gear some manufacturers have produced a plant which will develop a heavy milliamperage at medium voltages for radioscopy, or alternatively a small current at a high voltage for therapy. The exhibit of X ray tubes suggested that the gas tube has almost disappeared. The majority of hot cathode tubes shown were of the metalix type. The ray-proof shield which allows only a cone of rays to issue from the tube, together with the single central suspension of the latter, has led to simplification in the design of tube carriers, and supports for this type of tube are now made by most X ray firms. Attempts have been made to produce a shock-proof X ray apparatus, and a unit of this type for radioscopy was to be seen at the exhibition. In this case the transformer and tube were enclosed in an earthed metal tank which was mounted after the manner of an X ray tube. Apart from the advantage of being shock-proof, a greater flexibility of movement than is usually possible is claimed for this method of mounting both transformer and tube. A noteworthy feature of the radiographic equipment was the attempt made by some manufacturers to facilitate the taking of stereoscopic pictures in rapid succession. The stereoscopic binocular gives an excellent, though reduced, stereoscopic picture at any distance from a pair of stereoscopic radiograms placed side by side. To obviate the distortion often seen in earlier radiograms, most firms now incorporate in their equipment means whereby the X ray tube may be placed at a distance of six feet from the film. X ray manufacturers have sought to obtain greater flexibility and smoother travel of the movable parts of radiological apparatus, and the exhibits in general bore testimony to the success they have achieved.

THE ACTION OF LEAD ON THE CHORIONIC EPITHELIUM.

EARLY in 1925 a paper was published in the *Journal of Obstetrics and Gynæcology of the British Empire* by Prof. Blair Bell and others in which it was demonstrated that lead, in suitable doses of a suitable preparation intravenously administered, produced coagulation necrosis of the chorionic epithelium in the pregnant rabbit without damage to the maternal tissues—an effect not produced by the other metals tested. A subsequent investigation by M. M. Datnow, also a member of the staff of the Liverpool Medical Research Organisation, published in the same journal (1928, xxxv., 693), confirmed these findings, but showed that this property is more evident with certain preparations of lead than with others, and that in regard to all the preparations examined the chemotherapeutic index was not high. The importance of these observations was related to the working hypothesis of Blair Bell that malignant development in a somatic cell is a structural and functional reversion to the chorion epithelial type which is able to live independently and parasitically, and is in other respects also normally malignant, and that a toxic agent which will destroy the chorionic epithelium should—other conditions being equal—also be lethal to the cancer cell. The work at Liverpool has met both with support and criticism, the latter being no doubt often founded upon the results obtained from the employment of inefficacious preparations, but, until recently, there seems to have been no satisfactory attempt by independent workers to confirm or refute the clearly stated results obtained in Liverpool—results that, in so far as they were new, conflicted with previous views as to the manner in which lead causes abortion, of itself a well-known fact. In the recent issue, however, of the beautifully produced and illustrated *Archivio dello Istituto Biochimico Italiano*, edited by Prof. Lorenzini (1929, i., 193), N. Dallera has published with coloured histological drawings a considerable research on this subject, entitled "L'azione del piombo sulla cellula coriale," from which the work of the Liverpool School receives much confirmation.

Dallera, in his investigations concerning the abortive action of lead in rabbits, studied the action of doses smaller than those which provoked abortion, and ascertained the effects of different doses on the chorionic epithelium and on the placenta generally. In all the animals submitted to experiment the urine was examined, and subsequently a histological investigation was made of the liver and kidneys. Fifty-three animals between the eighth and twentieth day of pregnancy were used. Of these, 21 received injections of Christoni's colloidal sulphite of lead, chemically prepared. Twenty-five animals received the colloidal lead electrically prepared by Prof. Ganassini, with the addition of sodium thiosulphate, the action of which has been extensively studied by Prof. Lorenzini and Dr. Simon; to seven animals

---

[3] Perry, C. Bruce: Arch. Dis. Childhood, 1929, iv., 247.

Dezani's organic non-colloidal preparation of lead was administered. The following conclusions were reached: 1. Lead, when introduced intravenously into the pregnant rabbit in small repeated doses, shows a selective poisonous action on the chorionic epithelium. 2. The following changes in the chorionic epithelium, and further in the placenta are progressive, and depend on the dosage: (*a*) Swelling of the syncytial layer of the chorionic villi, with alterations of the protoplasm and consequent ischæmia in regard to the maternal blood-spaces of the placenta. (*b*) Necrosis of the syncytium with congestion of the placental blood-spaces. (*c*) Complete disappearance of the syncytium, breaking down of the supporting septa, and the production of hæmorrhagic areas with necrosis of the fœtal placenta. 3. The pregnant rabbit reacts to lead with toxic symptoms with smaller doses than when not pregnant. (Dallera did not attempt to define the abortion dose as was done by Blair Bell and his fellow-workers.) 4. There are no essential differences between the changes of the placenta in relation to the different periods of pregnancy. 5. The action of lead may not always be confined to the fœtal ectoderm, but some derivatives of lead may also affect the maternal organs to a degree that varies with different preparations. 6. The colloidal lead prepared at the Institute of Biochemistry of Italy acts chiefly on the placenta, and in order to produce slight temporary lesions in the liver it is necessary to inject doses four to five times greater than those which markedly damage the chorionic epithelium. (This preparation appears, therefore, to have a higher chemotherapeutic index than the preparations used in Liverpool.) 7. The metallic colloidal lead is that which best realises the essential postulate of chemotherapy—that is, the greatest divergence between the active dose and the toxic dose. 8. The distribution of the lead conveyed in different preparations varies. The colloidal lead localises itself specially in the placenta, and only in very heavy doses also in the liver (which, however, does not present any alteration). The lead sulphite and Dezani's soluble salt are found only in small quantities in the placenta, and in large amounts in the liver and kidneys with evident lesions in these organs. From these data it appears that the colloidal state of the lead is of great importance.

THE MORALE OF THE BLUEJACKET.[1]

A LITTLE book, described on its appropriately blue "jacket" as a social study of the lower deck, is worth the serious attention which its modest contents hardly claim for it. In a recent issue of THE LANCET we reviewed a study of the mental reactions of the sailors of the fleet in war by Dr. Thomas Beaton, *himself then* a Temporary Surgeon-Lieutenant, R.N., and thus possessing full opportunity for his investigations; and this skilled alienist concluded that "the training of the sailor has for its first aim the rendering of the individual, not into a precise automaton, but into a intelligent and coöperating personality, and in the achievement of its purpose it cannot be too highly praised"—in other words, the object of training was to turn out a good ship-mate, since incorrect conduct makes a man a bad ship-mate. How the education which has earned so high an encomium effects its purpose, what are its reactions in daily life on the lower decks of ships, we learn from Mr. Trystan Edwards's account of his three years' service wearing "the three rows of tape" on his blue collar as a seaman "for the duration" (1915–18). Judged even in comparison with the life of the public school and university man, he did not find the training wanting. It is disciplinary training, he says, which while it saves the seaman from carelessness and from panic in times of stress, gives him health, a sense of cleanliness, and steadiness of nerve, and makes him energetic and alert, as well as good-mannered. On the lower deck there is no word for good manners—they are a sine qua non; the few and new without them are called "ignorant," but it is charitably expected that they will soon acquire them. The author found the men habitually cheerful, often singing, working very hard, and always wanting sleep. And there is a significant comment that the men of exceptionally fine physique and character were nearly always from large families whose parents had both married young. He covets the bluejacket training for more of the youth of England, and concludes his important study thus: "Complete liberty and equality there can never be . . . . .fraternity finds nowhere a greater measure of fulfilment than in the humane company of those who serve under the White Ensign." But it will surprise everyone, and especially parsons, to learn why it is the seamen like church on board (p. 123).

THE STUDY OF TROPICAL MEDICINE.

THE transactions of the seventh congress of the Far Eastern Association of Tropical Medicine appear in a volume[1] containing 97 communications which occupy some 871 pages. The chief subjects discussed are plague, cholera, dysentery, sprue and intestinal infections, bacteriophage, leprosy, tuberculosis, typhus-like diseases, leptospiræ, and malaria in all its aspects. To the section on plague such well-known authorities as F. P. Mackie, Wu Lien-Teh, Fabian Hirst, and N. H. Choksy appear. The Joint Meeting of the Expert Plague Committee of the League of Nations Health *Organisation and of this Association* stressed the importance of further inquiries into the methods of destruction of rats and fleas, the comparative epidemiological rôle of various species of fleas in plague transmission in selected areas in India, the survey of plague in wild rodents in Northern Asia, and the part played by grain and cotton in the dissemination of plague. As regards prophylaxis and therapeutics, the speedy preparation of antiplague vaccine, the possibility of producing a plague antitoxin serum, further studies on anti-plague bacteriophage and its practical application were considered. Pneumonic *plague is dealt with separately in these Transactions;* the incidence of bubonic plague, and its relation to pneumonic plague, is considered important, as well as the possible existence of a special ultra-virus or filter-passing form of *B. pestis*. The subject of cholera stimulated a number of communications. Lieut.-Colonel A. J. H. Russell is responsible for statistical studies in its epidemiology. C. L. Dunn and S. Khan show that cholera is not endemic in Hardwar, but is an accompaniment of pilgrimages. J. W. Tomb and G. C. Maitra, from experiences gained in Asansol Mining Settlement, believe that the non-agglutinating intestinal vibrios take on the agglutinating characteristic under certain still unrecognised conditions in the human intestine.

The dysenteries of Bengal have been studied by A. C. Ukil, who finds mild forms of bacillary dysentery to be the form most prevalent. F. P. Mackie, N. H. Fairley, and the staff of the Haffkine Institute, Parel, Bombay, contribute a report of progress on the sprue inquiry. P. Manson-Bahr, L. M. Maybury, and P. H. Martin testify to the therapeutic value of blood transfusion in sprue anæmia. S. S. Sokhey writes upon the pancreatic and liver functions in sprue. Special interest centres on the accounts of bacteriophagy and bacteriophage by F. d'Herelle. He sets out clearly his reasons for regarding the bacteriophage as a living being, an ultra-virus parasitic on bacteria and which provokes in them an extremely contagious disease. With Major R. H. Malone and M. N. Lahiri he believes that in the treatment of cholera with bacteriophage the cultures of this substance should be endowed with maximum virulence and maximum activity. Lieut.-Colonel Morrison and Major C. de C. Martin state that bacteriophage alone has been proved as effective in the treatment of bacillary dysentery as is orthodox treatment given in control cases.

[1] Three Rows of Tape. By A. Trystan Edwards (ex-Able Seaman, R.N.). London: William Heinemann, Ltd. 1929. Pp. 167. 6s.

[1] Transactions of the Seventh Congress, British India, 1927. Edited by Lieut.-Colonel J. Cunningham, C.I.E., B.M., M.D., I.M.S., Director, Pasteur Institute of India, Kasauli, British India; Chief Organising Secretary for the Seventh Congress. Calcutta: Thacker's Press and Directories, Ltd. Vol. II. 1929. Pp. 871.

The leprosy section is particularly full. E. Muir propounds his latest views on the treatment with special reference to the employment of potassium iodide; R. Row amplifies his well-known work on the curative value of tubercle bacillary autolysate in leprosy; it must be remembered that it is still doubtful whether this action is specific or whether it is due to non-specific protein. E. V. Pineda contributes an important paper on the presence of the leprosy bacillus in 53 per cent. of the placenta and umbilical cord of advanced sufferers of the disease. R. Inada contributes a short comparative study of leptospiræ. R. McGuire writes on colour variations in the fungus of Dhobie's itch, and D. G. Panja believes he has cultivated the organism responsible for dandruff, which he has termed *Malassezia ovalis*. Typhus and typhus-like diseases also attracted much attention, notably from J. W. D. Megaw and C. Strickland. Under the section of Protozoology, R. Knowles and B. M. das Gupta have studied the influence of the thyroid gland on the course of a protozoological infection.

No less than 30 papers are devoted to the question of malaria, divided under three headings—control, general considerations, and treatment. Sir Malcolm Watson writes informatively on the future of malaria control in the Federated Malay States. Colonel S. P. James, Drs. W. D. Nicol and P. G. Shute have studied the habits of anopheles in relation to their rôle in the spread of malaria from observations made in England, and they have also made experiments on the treatment of malaria, from which it appears that thorough and prolonged quinine treatment of the primary attack has no more effect in preventing a true relapse than has intensive treatment by quinine during the acute phase.

A MEMORIAL TO JOHN THOMSON.

ON Saturday, Dec. 14th, a memorial to the late Dr. John Thomson was unveiled by Sir Thomas Barlow in the Royal Hospital for Sick Children at Edinburgh. The memorial takes the form of an inscribed marble panel with a bronze portrait medallion by Mr. Pilkington Jackson, placed opposite the entrance of Dundas Ward, where Thomson did such a large part of his work. In addition, a medal is to be awarded by the University of Edinburgh for a thesis or original investigation of special merit and dealing with children. Recalling Thomson's appointment in 1884 to one of the resident medical posts at the Hospital for Sick Children in London, Sir Thomas confessed that at the outset of their acquaintance he was not impressed by Thomson's personality, while some of his contemporary residents esteemed him but lightly. They little knew then what a reserve of quiet power, sound method, and good judgment lay beneath that modest, half-deprecating demeanour. A slight hesitancy of speech was the outcome of a resolute determination to cultivate accuracy of statement. Good botanist that he was, he had been trained in sound observation. When his two years at Great Ormond-street were completed and he returned to Edinburgh, Thomson was almost immediately appointed physician to the New Town Dispensary, where he soon developed a successful children's clinic, and shortly afterwards he was elected assistant physician to the Children's Hospital. His most important contribution to medical knowledge was, in Sir Thomas's opinion, his account of pyloric stenosis in infants; an exhaustive report of 100 cases under his own care during a series of years opened the eyes of medical men to the serious importance of its early recognition, and the vital indications for its treatment. In this as in all his work he was keen to share his knowledge in the give and take of real fellow workers. He was generous in acknowledging the help of his colleagues, whether older or younger; jealousy and self-advertisement were both unknown to him. Later in his career Thomson set himself to engage the interest of the mothers of mentally deficient children in simple methods of wakening intelligence and cultivating self-control. He was determined in his instructions to use no word or phrase which might discourage or humiliate the mothers, holding by the maxim, "By hope are ye saved." To those that knew him best, Sir Thomas concluded, the memory of John Thomson would always be that of a modest gentle true-hearted soul, with a passion for verification and a deep desire to widen the boundaries of beneficent knowledge. The same sentiments were expressed in other ways by Prof. G. F. Still, Dr. Logan Turner, and Dr. Robert Hutchison, who were also present to do honour to a great pædiatrician. In accepting the commemorative medal on behalf of Edinburgh University the Principal, Sir Thomas Holland, pointed out its economic as well as its humanitarian value. There was, he said, as yet no organised research into the psychology of the child under the age of five years, with the result that much harm was done in our schools through ignorance.

TREATMENT OF CATARACT AND GLAUCOMA IN MADRAS.

Lieut.-Colonel R. E. Wright's professional report[1] of the Government Ophthalmic Hospital, Madras, for the year 1928 will be of interest to ophthalmic surgeons everywhere. The average number of operations for senile cataract alone is over 1500 a year. Precautions to prevent squeezing on the part of the patient while on the table and to secure quiet afterwards include novocain injections to block the seventh nerve and into the orbit, and the drugging of the patient to such an extent as sometimes to amount to a kind of twilight sleep. Various forms of conjunctival bridge flaps have been tried during the year in order to maintain the lips of the section in contact, but the natives, it seems, are more liable to conjunctival bleeding than Westerners, and blood clot under the bridge sometimes interferes with healing. In Colonel Wright's opinion no form of bridge is so efficient as suturing the lips of the section. Various types of operation are performed, but in the great majority of cases the capsulotomy operation is chosen, usually with a peripheral iridectomy. In a proportion of cases Barraquer's intracapsular extraction is performed, a procedure not now popular in this country; but no mention is made of Colonel Henry Smith's intracapsular method.

In the Madras Hospital they classify all their primary cases of glaucoma, whether acute or chronic, into posterior segment types and anterior segment types. In the former the important factor is the increase in the volume of the vitreous: the anterior chamber early becomes shallow, but the cupping of the disc does not appear till late. In the anterior segment type, on the other hand, the anterior chamber is not shallow and cupping of the disc is an early symptom, and in these cases it is suggested the blocking of the angle of the anterior chamber takes a more important part in causation. A systematic investigation of 100 cases was undertaken along these lines, which may help towards resolving the perennial controversies. As to non-operative treatment or treatment preliminary to operation, eserine drops are the great stand-by, but in certain cases their effect was greatly enhanced by simultaneous employment of adrenalin. Glaucosan and amino-glaucosan are not so highly spoken of. In well-marked cases a decompression operation, preferably trephining, was always necessary eventually.

Elsewhere in the report there is reference to an epidemic of superficial punctate keratitis which occurred in 1928. Over 800 cases were seen before the end of that year. Like herpes febrilis it appears to be due to a non-filtrable virus, and is probably identical with the keratitis described by Herbert in

---

[1] Madras Government Press, 1929. Rs. 2.

Bombay in 1901, and by Kirkpatrick in Madras in 1920. The affection is known to Western ophthalmologists but not in an epidemic form.

AN IDEAL OPERATING TABLE LAMP.

WHAT the surgeon needs when he is operating is an illumination of the field, concentrated and yet practically shadowless, along with a high vertical component of intensity, ensuring penetration into deep cavities. The intense light must be confined to the wound area, but at the same time the room must be sufficiently illuminated to prevent difficulties from mal-adaptation of the eye. The high intensity should be produced without striations or glare, and the source of light should be as unobtrusive as possible. At a meeting of the Illuminating Engineering Society, held at the Home Office Industrial Museum on Dec. 10th, Mr. Ernest Stroud described a special unit designed to fulfil all these conditions. It consists of a number of prismatic plates formed into a panel or false ceiling of relatively large area. The construction of the plates is such as to refract the light rays which reach them into a converging beam of high intensity. Each plate is 12 in. square, and made up of quarter-concentric prisms, and four plates are grouped into one large lens 24 in. square of 12 in. focus length. The complete unit contains 15, 18, or 21 of these 4-plate groups, its dimensions being 6 ft. wide by 10, 12, or 14 ft. long. Over each group of plates is fitted a lamp and reflector in such relation to each other that the maximum beam strikes the centre of the operating area; thus with a 15-group system the combined 15 concentrating beams coming from different directions build up and focus their rays over the predetermined area. The method differs from a reflector system in the largeness of the area whence the light comes, which secures adequate diffusion, avoids harmful shadows, and absolutely avoids glare. The overflow from the lens system gives sufficient general illumination to avoid contrast glare, and the optical characteristics of the lens are such as to allow for the varying thicknesses of bodies and heights of tables. With a 15-lens system employing 15 lamps of 150 watts each, or 2250 watts in all, the maximum horizontal illumination is 1050 ft. candles, on a plane 45° from the vertical it is 725 ft. candles, and on a vertical plane facing the centre of the table 175 ft. candles; these high intensities being developed without any semblance of glare. The smooth sides of the glass plates are towards the source of light, and since the complete unit can be totally enclosed so as to form the ceiling of the operating theatre there need be no collection of dust and no obstruction projecting into the operation theatre.

A SCULPTOR OF YOUTH.[1]

A BEAUTIFUL book has recently appeared describing the work in marble and bronze of that accomplished sculptor, Tait Mackenzie, a professor in the medical school of the University of Pennsylvania. The importance of Tait Mackenzie's sculpture lies in the fact, as Mr. Christopher Hussey says in a critical résumé of Mackenzie's work, that we have here the first considerable attempt since the marvellous accomplishments of Athens to take for the sculptor's main subject the athletic ideal. For many years before his present appointment Mackenzie was director of physical education at McGill University, and in 1894, when he first occupied that chair, he had made few or no attempts in sculpture, though undoubtedly it was then that he was receiving the formative influences which enable him to-day to express his ideals of motion and rhythm in the human body. When, as now, athletics occupy so prominent a place in educational life it is certain that the Greeks have once again shown the way to great accomplishments for those who have the necessary receptive attention, instruction, and fine thought. The contents of Mr. Hussey's book consist largely of excellent representations of Mackenzie's best known work, with a running commentary of appreciation which though enthusiastic appears always to be justified. While the large imaginative groups will command most of our admiration—and rightly so—medical men will be interested in the portrait medallions, for they include representations of, among others, William Osler, Crawford Long, Wilfred Grenfell, Chevalier Jackson, Robert Jones, Weir Mitchell, W. W. Keen, and Charles Brockden Brown. Brockden Brown's chief claim to public interest is that he is always cited as the first American novelist, with the funny suggestion that he imitated William Godwin, but medically speaking he is remarkable in that he wrote in "Arthur Mervyn" a wonderful description of an epidemic of plague from personal observation of the horrors that fell upon Philadelphia at the end of the eighteenth century.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

LVIII.

INTERPRETATION OF RADIOGRAMS OF THE ALIMENTARY TRACT.

PART V.*—LARGE INTESTINES.

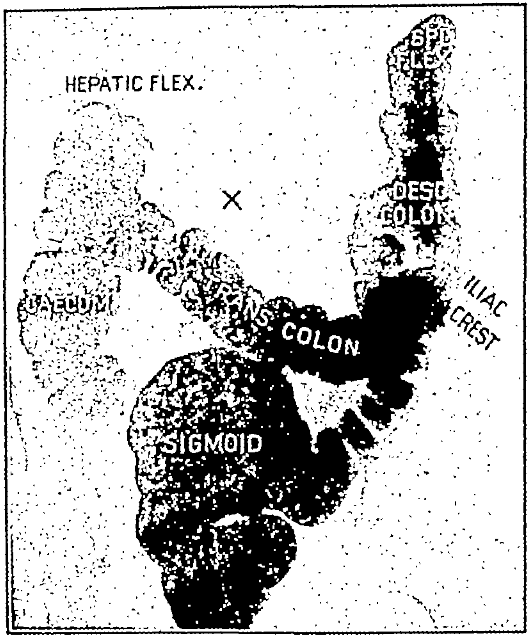
THE food arrives in the cæcum in about four hours and should be somewhere near the splenic flexure in nine hours, but the times at which it arrives at different parts are so extremely variable that even approximate figures are far too definite. The normal colon as seen after feeding with barium is shown on Fig. 23. A typical picture of a normal colon distended by an enema is shown in Fig. 24. Individuals vary to an amazing degree, and even yet the movements of the large intestine are not clearly understood. There is no peristalsis in the ordinary sense and the shadow of the food in the colon remains inert hour after hour. Wingate Tod, using serial films over a long period (a very risky procedure for the subject), thinks that he detects a very slow rhythmic peristaltic movement which we certainly do not detect on screen examination. Whether it is or is not present, however, the main factor in the movement of food through the large bowel is one that is unique and is not comparable to any other in the body. It is difficult to obtain observations, for the movement occurs only occasionally, at no fixed time, and without the slightest subjective sensation. What we observe is that the haustral shadows, the divisions in the intestinal shadow, disappear and that, quite suddenly, the whole column makes a forward rush, usually from the region of the hepatic flexure, the column passing quite rapidly on, perhaps as far as the sigmoid or even to the rectum. Sometimes there is a partial rebound, but within a minute or so the haustral segmentation has again appeared and it is once more a picture of still life. Movements such as this—mass movements as they are called—occur perhaps three times a day, but we do not know, for we only detect that they have occurred by the completely altered disposition of the shadows. The first mass movements that were seen were estimated to have occurred in three seconds, but later observations suggest a quarter of a minute as a more usual time. Naturally, therefore, the rate of progress through the large bowel cannot be gauged accurately. The limits of the normal, which are wide enough in the stomach, become wider and wider as we go further down the alimentary tract until in the large intestine

---

[1] Tait Mackenzie, a Sculptor of Youth. By Christopher Hussey. London: Country Life, Ltd. 1930. Pp. 107. With 14 figures and 91 plates. 25s.

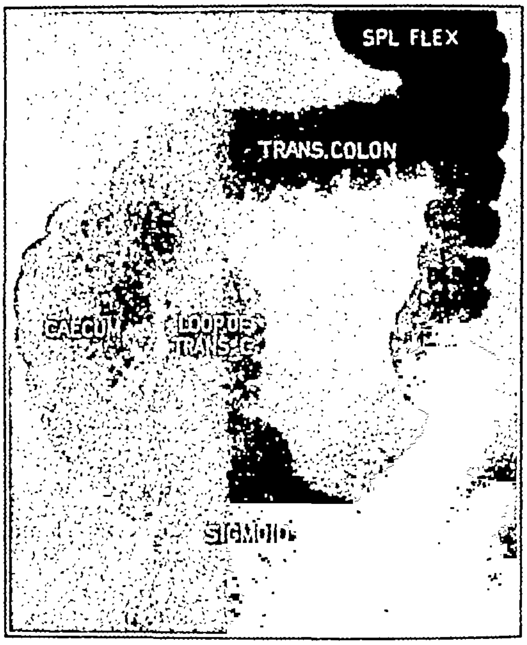
[1] Parts I., II., III., and IV., respectively on the Œsophagus, the Stomach, the Duodenum, and the Small Intestine with the Appendix, appeared in THE LANCET of Nov. 30th, Dec. 7th, 14th, and 21st.

FIG. 23.



Well-filled large intestine. Note the haustral segmentation. The hepatic flexure is rather higher and the splenic flexure rather lower than usual. The transverse colon is looped down over the descending colon. Such a loop is more common on the right than on the left—there is nearly always more or less of a loop. The ascending and descending parts of the splenic flexure are superimposed. The cæcum is not well filled—note the close anatomical relationship between the loaded sigmoid and the cæcum.

FIG. 24.



Normal colon distended with a rather large enema. Note the big loop of the transverse colon that drops down over the cæcum. The shadows in the right iliac fossa are blotted out by this loop. The haustral segmentation is usually not noted just after the enema is given but is noted within a few minutes—as the colon accommodates itself to the enema and as the discomfort passes off.

FIG. 25.

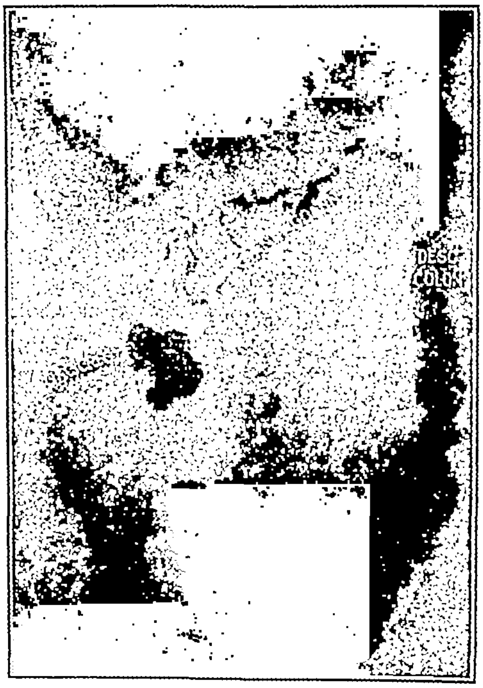


FIG. 26.

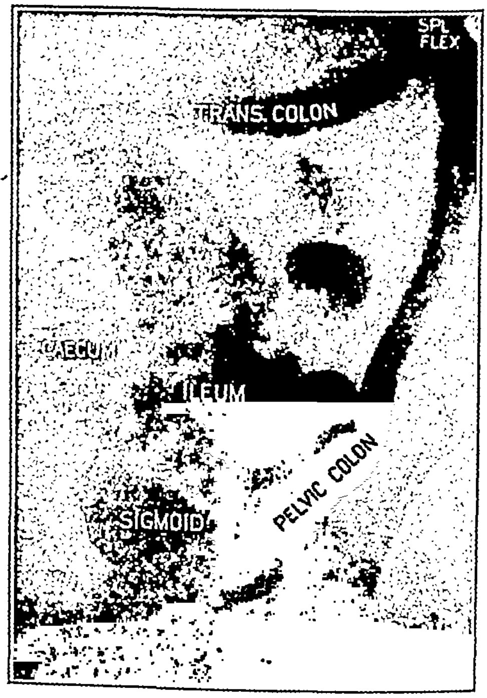

Fig. 25 shows "string" sign of colitis of the transverse colon. In Fig. 26 the opaque enema has flowed through the length of the colon and a portion of it has passed into the coils of small intestine. The "ribbon" appearance of the colon, with its absence of haustral segmentation is often associated with some forms of colitis. It is not pathognomonic, and in many cases disappears after an interval, especially if the bowels act.

FIG. 27.

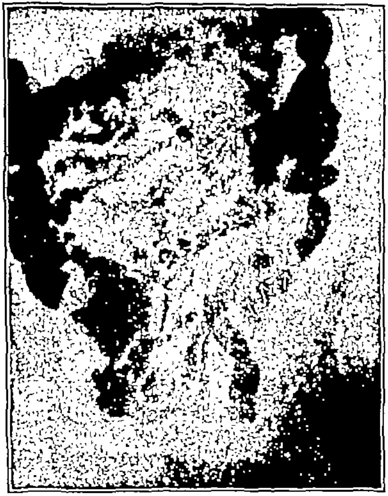

FIG. 28.

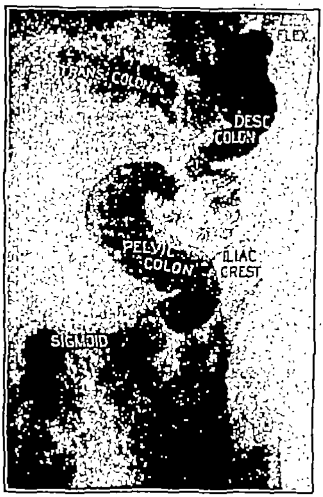

Fig. 27 shows a growth of large intestine after a barium meal, and in Fig. 28 the same growth is seen radiographed after an opaque enema.

they are almost impossible to define, making the study of constipation one of the most tricky and treacherous of subjects. Our very foundations are a quicksand of possible variables in which we make marks for our guidance—four hours to the cæcum, four and a half hours to the hepatic flexure, and so forth, but we know quite well that we shall be doing an injustice to any patient if we erect the structure of our diagnosis on such flimsy foundations. In the study of constipation, therefore, we can only accept definite extremes as our guides—incidentally never accepting the patient's statement as to whether he or she has had a satisfactory motion. On numerous occasions patients have stated that they have only had a very small motion when observation has shown that the whole of the opaque food has passed out. And sometimes they give the same reply on the following day, when we know that everything they have eaten between the two opaque meals has been voided within 24 hours. The number of patients who have an obsession as to bowel movement is not small.

We have been drilled into imagining that a movement of the bowels once in 24 hours is the normal habit to acquire, although certain extremists are nowadays trying to persuade us that this is not sufficient. But the fact of the matter is that there are extremely wide variations and what is normal for one subject is not necessarily normal for another. Two or three stools a day may be normal for some individuals, while others may live to as ripe, happy and healthy an old age on one evacuation a week. Such cases are, of course, rare, but I have seen one rosy-cheeked girl whose habit was one a month.

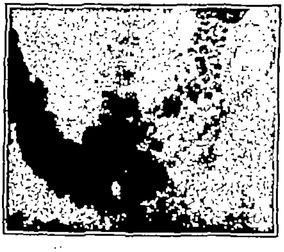
In the study of *constipation* we thus have to depend on following through from day to day and determining where the delay is occurring and why. Three types can be noted, namely: 1. Where the cæcum remains filled, and is of the large, sloppy type. 2. Where the food gets into the large intestine and remains inert for days. 3. Where the food reaches the rectum but there is no call to stool (dyschezia).

There are many forms of *colitis*, and there are no typical X ray pictures, with the single exception of what is known as the "string sign," that is, a string of opaque food running along the lumen of the gut (Fig. 25), but this is only seen in certain cases. There are various other appearances, none of them typical, which cannot be discussed in a brief space. The "ribbon" appearance of the colon which is often associated with colitis, but is not pathognomonic, is shown in Fig. 26.

Growths.

Growths of the large intestine may remain latent for long periods before giving symptoms. Obstruction is often the first, and probably the only, sign. The opaque food given by the mouth may fail to be held up at the obstruction. In the early stages we may find the affected area partially filled with traces of opaque food, lying in inequalities of the canal, but one can deduce nothing from the absence of such shadows. It is only in the latest stages of an obstructive lesion that the opaque food is held up actually behind the growth—apparently the food is thrown back either by the associated spasm or by the rebound when the mass movement takes place. Whatever the mechanics, however, the fact remains that it is only in the latest stages that the gut immediately behind the obstruction becomes distended and allows the opaque food to gather in it.

FIG. 29.



Diverticulitis. Note the small "currant" shadows left in pockets. These are usually left filled or partially filled after the bowels have been emptied.

The picture of scattered air spaces, bounded below by fluid lines that indicate extending back pressure from an obstruction has already been referred to under the small intestine—it is obviously a case for the surgeon and the sooner he deals with it the better.

A number of fallacies in interpretation have given rise to many mistakes, the main one being the obstruction to the flow of the enema that may be caused by the brim of the pelvis or other bony projections. By raising the pelvis and other posturing this difficulty can usually be overcome. A pint of enema fluid should flow easily as far as the splenic flexure and even beyond. With two pints it is usually possible to fill the whole of the large intestine. *Definite obstruction at a certain point, coupled* perhaps with the presence of a tumour, makes the diagnosis of a growth reasonably certain. Fig. 27 shows a radiogram of growth of the large intestine after an opaque meal. Fig. 28 shows a radiogram of the same growth taken after an opaque enema. The *presence of filling defects must be looked for through*out the whole length, more particularly, in my experience, in the region of the splenic flexure. Rotation of the patient is always necessary to show this flexure properly—it may, however, be difficult to get satisfactory photographic records in this position. There is one fallacy connected with the palpation of thickening of the colon which should be pointed out—namely, that one can frequently palpate the pelvic colon as a sausage-shaped mass which is not always present, and seems to be due to an intermittent and painless spasm. Sometimes, at any rate, it appears to be associated with a chronic appendix, but what the connexion is I do not know.

The presence of *Hirschsprung's disease*, like that of an acute obstructive lesion, is indicated by collections of air and fluid, but the chronic clinical picture and the distended abdomen make the diagnosis clear. Incidentally some of these cases at any rate are not congenital, but are acquired, being due to some adhesion or thickening in the sigmoid or rectum. The X ray picture of these cases shows the large, distended and redundant colon. In extreme cases it would take several times the normal quantity of enema to fill the large intestine. There is no difficulty in getting the enema to flow and the obstructive lesion, if it is still present, is of a valvular type and only interferes with the downward passage of the fluid.

Diverticula of the large intestine (Fig. 29) are common and may give rise to considerable palpable thickening, but radiographically the presence of pockets of opaque material like currants, left around the intestine after the bowels have been moved, is quite positive evidence as to the nature of the condition. It is a curious fact that these pockets are much more certainly demonstrated by the residue of the opaque meal than by giving an enema. The appearances of a well-established case are quite typical, but in the early stages the diagnosis is not by any means certain or straightforward.

CONCLUSION.

As to the value of the opaque meal investigation—it depends entirely on the experience and skill of the man who conducts the examination. No elaboration of apparatus or perfection of technique in the production of X ray films can make up for lack of skill and experience in this highly specialised work in which a thorough knowledge of the medical problems involved is fundamental. The time has almost if not quite come when a surgeon should not open an abdomen, at any rate for certain lesions, unless the report of the radiologist is positive. The responsibility for operation or refraining is knocking more and more at the door of the radiologist.

A. E. BARCLAY, M.D. Camb.,
Lecturer in Radiology, University of Cambridge.

THE CITY DISPENSARY.—This old City of London charity, which dates from 1789, reports a deficiency of income over expenditure of £227 and, not for the first time a portion of the very small invested capital has had to be sold. The patients of the dispensary, who are attended free by an honorary medical staff, have made 12,707 attendances in the last two years. The Lord Mayor, who is President, is appealing for help.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

ON Dec. 17th a meeting of the President and General Council of King Edward's Hospital Fund for London was held at St. James's Palace for the purpose of awarding grants to hospitals and convalescent homes, including the Thank-offering Fund Distribution.

The Prince of Wales, who was in the chair, read the following message:

Buckingham Palace.

> "The King is glad to hear that King Edward's Hospital Fund is again able to distribute £250,000 and that the hospitals will also benefit so greatly by the Thank-offering Fund. His Majesty wishes the Council every success during the coming year.—STAMFORDHAM."

Continuing, the Prince said that if he took as his texts, first, the impressive little table at the end of the Distribution Committee's list of grants (see page 1382) and, secondly, the different sums of which the total was made up, he would have covered the chief activities of the Fund during the year. The ordinary distribution was again £250,000. Last year, when the Fund had reached the round quarter million, that sum was thought of as a mile-stone where it might be good policy to rest awhile, lest they went too fast and perhaps be forced to retreat; but the Distribution Committee's report showed that the work of the hospitals did not stand still and, if the distribution remained at £250,000 for more than two years, the hospitals would suffer. The Thank-offering Fund had enabled them to meet the increased demands of hospitals this year, but the continued increase in hospital work would have to be met next year by distribution beyond the £250,000. The Pension scheme for nurses and hospital officers now covered some 30,000 beds, but the growth of the scheme would mean larger grants from the King's Fund. The amount available from the Thank-offering Fund to the King's Fund was £220,000 and of this, £105,000 represented the splendid gift of "Audax" which would be invested. The special distribution of this fund included a large grant to the new King George Hospital for the extreme east of Greater London. But the £220,000 was only a fraction of the sums subscribed to Thank-offering Funds throughout the country. The whole of the 4 grammes of radium purchased with Sir Otto Beit's gift of £50,000 had been allocated among 20 hospitals, and they had this morning received for the Radium Fund £10,000 from Mr. Roger C. Parr, whom he thanked for his generous gift. After referring to the report of the committee dealing with the Local Government Act and the hospital system, His Royal Highness pointed out that coöperation between the King's Fund, the Teaching Hospitals, and the British Hospitals Association had been effected and a joint committee appointed to devise a representative Voluntary Hospital body for the consultations with the London County Council required by the Local Government Act.

The Prince closed his speech by thanking all those who had helped to carry on the work of the Fund during the year, mentioning especially Sir Cooper Perry, Chairman of the Distribution Committee, Mr. Eardley Holland, Chairman of the Radium Subcommittee, Prof. Russ, the technical adviser, Lord Donoughmore, Chairman of the Management Committee, who had also been treasurer of the Thank-offering Fund, Lord Luke, Chairman of the Revenue Committee, and, in connexion with the thanksgiving for the

King's recovery His Highness asked how could he omit to mention the name of Lord Dawson. He added that a testator, happily still living and vigorous and most emphatically anonymous, was, by his will, making the King's Fund the permanent landlord, so to speak, of a large house and grounds to be used as a convalescent home, and was setting aside a trust fund to help with its maintenance.

Treasurer's Statement.

Mr. E. R. Peacock (the hon. treasurer) said that the estimates laid before the Council in November justified a distribution of £250,000 for the second year in succession, but left no margin. Last year the cost of special pension grants was met from unexpected legacies received after the ordinary distribution had been fixed. This year the position was similar. A legacy of £20,000 had been received, and as the pensions grants amounted to £13,734, there was every reason to anticipate that they could be covered in the same way as last year. Invested funds had been increased by further sums of £7000 from the estate of Mr. Samuel Lewis and £1520 from that of Sir Julius Wernher, and by £15,000, the first of the seven yearly instalments of the gift of £105,000 from "Audax" through the Thank-offering Fund. Taking into account the additions made to general fund legacies since the date of the estimates, the receipts from that source amounted to £67,000, a figure almost exactly the same as that of last year. Annual subscriptions were slightly larger. But a smaller amount than usual had been received in donations this year. Every endeavour to ensure that the receipts from voluntary sources, which now came to £90,000 a year, must be fully maintained.

The League of Mercy.

Lord Marshall then made the annual statement on behalf of the League of Mercy. (The report of the annual meeting of the League of Mercy was published in THE LANCET of Dec. 21st, p. 1320).

Grants to Hospitals and Convalescent Homes.

The Chairman of the Distribution Committee (Sir Cooper Perry) presented the report of the Committee on the Distribution to Hospitals (including Recovery and Convalescent Branches). The report showed that 143 hospitals had applied for grants as against 141 in 1928. Ninety-four hospitals had joined the Pension scheme, as against 89 in the previous year. The total annual distribution amounted to £261,784, and when the Thank-offering Fund was added, the grand total reached £376,784. Of this, £239,709 was for maintenance, and £136,035 for schemes of capital expenditure, and it also included a grant for the building fund of the new King George Hospital at Ilford. The proposal for the provision of a single large hospital on the Ilford site, he said, was the result of the amalgamation of several schemes for providing for the needs of the increasing population of the eastern part of Greater London. It was drawn up at a series of conferences for which the King's Fund acted as convener, and in which representatives of the London County Council, the Ilford Hospital, and the local hospital funds of Barking and Becontree took part. The King's Fund made a grant of £10,000 out of the Wells legacies distribution on the understanding that the London County Council would contribute a similar sum. A grant of £2000 set aside for the extension of the Ilford Hospital had also been transferred to the building fund of King George Hospital. 2300 mg. of radium had been actually delivered to 15 hospitals out of Sir Otto Beit's gift, the remaining 1700 mg. were being delivered as fast as containers and needles could be supplied.

Lord Somerleyton (hon. secretary) presented the schedule containing the lists of awards to hospitals (including Recovery and Convalescent Branches) as follows.

*List of Awards.**

	£
Acton Hospital (of which £250 to deficit on extension)..	951
All Saints' Hospital	78
Baby Clinic Hospital (Kensington) (of which £100 towards the acquisition and adaptation of new premises)	186
Beckenham Cottage Hospital	450
Belgrave Hospital for Children	1,700
Bermondsey Medical Mission Hospital	50
Blackheath and Charlton Hospital (of which £50 towards improvements)	221
Bolingbroke Hospital (of which £100 to deficit on new block)	2,218
Brentford Hospital (of which £150 towards additional staff accommodation)	267
British Hospital for Mothers and Babies, Woolwich ..	550
Bromley (Kent) and District Hospital (of which £200 towards extension)	375
Carshalton and District Hospital (of which £250 towards extension)	335
Catholic Nursing Institute	15
Central London Ophthalmic Hospital (of which £350 towards extension)	706
Central London Throat, Nose and Ear Hospital (of which £500 to deficit on extension)	866
Charing Cross Hospital (of which £500 towards new casualty department, &c.)	4,500
Chelsea Hospital for Women (including Convalescent Home at St. Leonards)	1,115
Cheyne Hospital for Children (including Country Branch at St. Nicholas-at-Wade) (of which £100 towards improvements at country branch hospital)	450
City of London Hospital for Diseases of the Heart and Lungs (Victoria Park)	3,664
City of London Maternity Hospital	1,304
Clapham Maternity Hospital	301
Connaught Hospital	1,550
Croydon General Hospital	1,068
Deptford and Greenwich Babies' Hospital (of which £100 towards rebuilding and extension on new site) ..	150
Dreadnought Hospital (Seamen's) (including Albert Dock Hospital, Hospital for Tropical Diseases, Sanatorium at Liphook, and Convalescent Home at Cudham) ..	1,525
East End Maternity Hospital (of which £250 to deficit on acquisition of adjoining building and its adaptation for nurses' quarters)	925
East Ham Hospital (of which £500 to reduce deficit on equipment of new general hospital)	1,545
East London Hospital for Children (including Convalescent Home at Bognor) (of which £250 to reduce debt)	3,336
Elizabeth Garrett Anderson Hospital (including Recovery Branch at Barnet) (of which £250 to deficit on reconditioning the existing hospital building in connexion with recent extension)	2,392
Eltham and Mottingham Cottage Hospital	50
Enfield War Memorial Hospital	350
Evelina Hospital for Children	1,290
Finchley Memorial Hospital (of which £200 towards new nurses' dining-room)	621
Florence Nightingale Hospital for Gentlewomen ..	311
Forest Hospital (Buckhurst Hill) (of which £100 to deficit on extension)	313
French Hospital	350
General Lying-in Hospital (of which £500 towards new nurses' home)	1,265
German Hospital	500
Golden-square Throat, Nose and Ear Hospital	495
Gordon Hospital for Fistula	80
Grosvenor Hospital for Women (of which £100 towards accommodation for resident medical officer and for nurses)	650
Guy's Hospital (of which £1000 towards provision of site for out-patient department extension)	12,818
Hampstead General and North-West London Hospital (of which £200 to deficit on new operating theatre and emergency beds)	3,022
Hampstead Hospital for Children (in consideration of the fact that curable cases are admitted)	200
Hanwell Cottage Hospital	50
Harrow Hospital (of which £200 towards extension) ..	376
Hendon Cottage Hospital	300
Hornsey Central Hospital (of which £150 towards new nurses' home)	380
Hospital for Consumption, Brompton (including Sanatorium at Frimley) (of which £200 to deficit on improvements)	1,687
Hospital for Epilepsy and Paralysis (of which £150 towards extension)	2,103
Hospital for Sick Children (including Country Branch at Tadworth)	4,378
Hospital for Women (Soho-square)	1,131
Hospital of St. John and St. Elizabeth (of which £200 towards nurses' home extension)	1,000
Hostel of St. Luke (of which £25 towards new larder) ..	125
Ilford Emergency Hospital	653
Infants Hospital (including Convalescent Home at Burnham) (of which £250 towards extension) ..	605
Invalid and Crippled Children's Society's Hospital (Canning Town)	500
Invalid Children's Aid Association Heart Hospital, West Wickham	300
Italian Hospital	300

---

* The Distribution Committee draw attention to the fact that it must not be assumed that the reduction or absence of a grant implies dissatisfaction.

	£
Jewish Maternity Home (of which £100 towards provision of clinical laboratory)	210
Kensington, Fulham, and Chelsea General Hospital (of which £250 towards extension)	351
King Edward Memorial Hospital (Ealing) (of which £200 to deficit on extension)	1,000
King Edward VII.'s Hospital for Officers	300
King George Hospital (see end of list)	
King's College Hospital (of which £100 towards improvements)	7,542
Kingston-upon-Thames Victoria Hospital	75
London Fever Hospital	600
London Homœopathic Hospital (of which £150 towards nurses' home extension)	1,908
London Hospital (including Recovery Branch at Reigate)	15,179
London Jewish Hospital (of which £100 to deficit on acquisition of adjoining site)	700
London Lock Hospital (of which £773 to Harrow-road Hospital and £397 to Dean-street Hospital, £250 of the latter being towards extension of out-patient department at Dean-street)	1,170
London Temperance Hospital (of which £750 to reduce debt, and £1,000 towards provision of new special departments and pay beds)	3,844
Marie Curie Hospital (of which £100 towards out-patient accommodation)	115
Medical Mission of the Good Shepherd, Babies' Home (Hoxton)	25
Metropolitan Hospital (of which £500 to deficit on nurses' home and accident wards)	4,444
Middlesex Hospital (including Convalescent Home at Clacton (of which £1,000 towards reconstruction) ..	9,119
Middlesex Cancer Hospital..	1,205
Mildmay Memorial Hospital (of which £100 towards extension of maternity pay block)	400
Mildmay Mission Hospital	1,100
Miller General Hospital for South-East London (including Convalescent Home at Bexhill) (of which £1,000 to reduce debt, and £500 to deficit on extension) ..	5,860
Mothers' Hospital of the Salvation Army	650
Mount Vernon Hospital (Fitzroy-square and Northwood)	842
National Hospital for Diseases of the Heart (of which £100 to deficit on extension of out-patient department)	512
National Hospital, Queen-square (including Convalescent Home at Finchley) (of which £250 to reduce debt and £250 towards extension)	4,512
Nelson Hospital for Wimbledon, Merton, and District (of which £250 towards provision of maternity pay-bed block)	1,000
North Islington Infant Welfare Wards	75
Norwood and District Cottage Hospital	304
Paddington Green Children's Hospital (including Convalescent Home at Slough)	620
Passmore Edwards Hospital for Wood Green, &c. ..	152
Phillips Memorial Homœopathic Hospital (Bromley) ..	15
Plaistow Maternity Hospital (of which £250 towards extension)	850
Poplar Hospital for Accidents (including Convalescent Home at Walton-on-the-Naze) (of which £100 towards extension of X ray department)	325
Prince of Wales's General Hospital (including Convalescent Home at Nazeing) (of which £1,000 to reduce debt and £250 towards new out-patient department)..	5,850
Princess Louise Kensington Hospital for Children (of which £200 towards further stage of new hospital) ..	600
Queen Charlotte's Maternity Hospital (of which £1,000 towards rebuilding and extension on new site) ..	2,703
Queen Mary's Hospital for the East End	4,644
Queen's Hospital for Children (including Convalescent Home at Bexhill)	4,019
Ross Institute and Hospital for Tropical Diseases (to the Hospital)	20
Royal Dental Hospital of London	320
Royal Eye Hospital	837
Royal Free Hospital (of which £1,000 towards extension)	7,424
Royal Hospital (Richmond) (of which £200 towards new operating theatre)	1,467
Royal London Ophthalmic Hospital (of which £250 towards provision of additional nurses' accommodation and wards)	2,963
Royal National Orthopædic Hospital (including Country Branch at Stanmore) (of which £250 to reduce debt and £500 to deficit on extension of country branch) ..	4,746
Royal Northern Hospital (including Royal Chest Branch in City-road, Recovery Branch at Southgate, and Convalescent Home at Clacton) (of which £500 to reduce debt and £250 towards provision of pay beds) ..	9,145
Royal Waterloo Hospital for Children and Women ...	2,820
Royal Westminster Ophthalmic Hospital (of which £500 to deficit on rebuilding and extension on new site) ..	1,206
St. Andrew's Hospital, Dollis Hill	303
St. Bartholomew's Hospital (of which £1,000 towards new operating theatres)	7,461
St. Columba's Hospital (of which £15 towards sun-blind for balcony)	431
St. George's Hospital (including Recovery and Convalescent Branch at Wimbledon) (of which £1,000 to reduce debt)	9,008
St. John's Hospital (Lewisham)	1,623
St. John's Hospital (Twickenham)	75
St. John's Hospital for Diseases of the Skin	302
St. Luke's Hospital for Advanced Cases	300
St. Mark's Hospital	484
St. Mary's Hospital	6,302
St. Mary's Hospital for Women and Children (Plaistow) (of which £250 to reduce debt and £500 to deficit on first stage of new out-patient department)	2,828
St. Monica's Home Hospital	125
St. Paul's Hospital	75
St. Peter's Hospital for Stone (of which £150 towards extension)	600
St. Saviour's Hospital for Ladies of Limited Means (Osnaburgh-street)	159
St. Thomas's Hospital	11,621
St. Thomas's Babies' Hostel (of which £100 towards new out-patient department)	125
Samaritan Free Hospital for Women (including Convalescent Home at Amersham)	1,337
Santa Claus Home (of which £25 to reduce debt and £20 to deficit on recent improvements)	120
Seamen's Hospital Society (*see* Dreadnought Hospital)	
South-Eastern Hospital for Children (Sydenham) (of which £100 towards new casualty department and pay beds)	1,235
South London Hospital for Women (of which £500 to deficit on new out-patient department)	1,682
Stoke Newington Home Hospital for Women	75
Streatham Babies' Hospital (of which £25 towards new sun-room)	50
University College Hospital (of which £250 towards extension of nurses' home)	9,187
Victoria Cottage Hospital (Barnet)	91
Victoria Hospital for Children (including Convalescent Home at Broadstairs)	2,671
Weir Hospital (Balham)	75
Wembley Hospital	100
West End Hospital for Nervous Diseases	1,538
Western Ophthalmic Hospital (of which £250 towards rebuilding)	553
West London Hospital (of which £250 to reduce debt)..	5,336
Westminster Hospital	5,505
Willesden General Hospital (of which £500 to reduce debt and £250 to deficit on completed stages of extension)..	3,074
Wimbledon Hospital (of which £200 to deficit on provision of children's wing)	700
Winifred House Invalid Children's Convalescent Hospital Home	25
Woodford Jubilee Hospital	105
Woolwich and District War Memorial Hospital ..	1,500

Special Grant.†

King George Hospital Building Fund (towards first stage of new hospital)	2,000
Total	£261,734

Summary.

	£
Grants to hospitals (including recovery and convalescent branches) for the year 1920 out of the ordinary distribution, per list above :	
Ordinary grants	248,000
Special grants towards expenditure under the Federated Superannuation Scheme for Nurses and Hospital Officers	13,734
Total grants	261,734
Grants to hospitals, out of the special distribution of the Thank-offering Fund for the King's Recovery ..	115,000
Total grants to hospitals and branches for 1920 ..	376,734
Grants to non-hospital convalescent homes	2,000
Total distribution for the year 1920, besides allocation of radium purchased with the gift of £50,000 from Sir Otto Beit	£378,734

Lord Ebbisham having seconded, the report was carried.

Sir Cooper Perry then presented the report of the Committee on the Distribution to Convalescent Homes not attached to particular hospitals, which stated that the number of applications eligible for consideration amounted to 53, as compared with 49 last year.

Colonel H. A. Wernher (hon. secretary) presented the list of awards.

Thank-offering Fund for the King's Recovery.

The Chairman of the Management Committee (the Earl of Donoughmore), in presenting the report of the Committee on the Thank-offering Fund for the King's recovery, said that he did so with profound thankfulness, and would like to say how much they had been encouraged all through by His Royal Highness's own great help and assistance at every stage of the work. He would like to emphasise the fact that the costs of collection had been nil.

The report showed the origin, history, and results of the Thank-offering Fund, and stated that it was realised from the moment the gift of "Audax" was received that the King's Fund could not by itself put forward a claim to be regarded as the sole channel for an expression of the feelings of the whole country, though the Committee pointed out that the hospitals of London were national institutions in the sense that they treated patients from all parts, and formed the largest centre of medical education and research. To this extent, and also because of its peculiar relation to its Royal Presidents, the King's Fund might be regarded as a national institution, but for the purposes of a thank-offering it was desirable that the public outside London should have an opportunity of selecting local charities; so provision had been made for earmarking contributions for local hospitals. The expenses were kept low, and would be more than covered by the bank interest on the money received while on deposit. The Management Committee recommend that an address be presented in the name of H.R.H. the President and the General Council to the King as Patron of the King's Fund, referring to the origin, history, results, and distribution *of the Thank-offering Fund, and tendering* to His Majesty their loyal congratulations on his recovery, and on his return to the full discharge of his high functions in Church and State.

---

† See (supra) Distribution Committee's report.

Lord Luke, in seconding the recommendation of the report, said that the difference between the £118,397 contributed in addition to the gift of "Audax," and the £115,000 distributed, was, like the expenses, covered by the interest received.

Mr. Leonard L. Cohen (hon. secretary) presented the list of awards as follows:—

	£
Acton Hospital (to reduce deficit on extension) ..	750
Baby Clinic Hospital (Kensington) (towards the acquisition and adaptation of new premises)	150
Belgrave Hospital for Children (to enable the hospital to extinguish the deficit on the completed stages of the extension)	1,000
Bolingbroke Hospital (towards provision of new block)	150
Brentford Hospital (towards provision of additional staff accommodation)	250
British Hospital for Mothers and Babies, Woolwich (to reduce deficit on the completed stages of the new hospital)	1,500
Bromley (Kent) and District Hospital (towards extension)	300
Carshalton and District Hospital (towards extension) ..	250
Central London Ophthalmic Hospital (towards extension)	750
Central London Throat, Nose and Ear Hospital (to reduce deficit on extension)	1,000
Charing Cross Hospital (towards provision of new *casualty department*, and other improvements) ..	1,000
Connaught Hospital (towards extension)..	600
Deptford and Greenwich Babies' Hospital (towards rebuilding and extension on new site)	250
Dreadnought Hospital (Seamen's), Greenwich (towards first stage of extension)	1,000
East End Maternity Hospital (to reduce deficit on acquisition of adjoining building and its adaptation for nurses' quarters)	1,250
East Ham Hospital (to reduce deficit on equipment of new general hospital)	2,500
Elizabeth Garrett Anderson Hospital (to reduce deficit on reconditioning of existing hospital in connexion with recent extension)	750
Finchley Memorial Hospital (towards provision of new nurses' dining-room)	300
General Lying-in Hospital (towards provision of new nurses' home)	2,500
Grosvenor *Hospital for Women (towards provision of* accommodation for resident medical officer and for nurses)	100
Guy's Hospital (towards provision of site for out-patient extension and to reduce deficit on recent improvements)	3,000
Hampstead General and North-West London Hospital (to reduce deficit on provision of new operating theatre and emergency beds)	200
Harrow Hospital (towards extension)	300
Hornsey Central Hospital (towards new nurses' home)..	600
Hospital for Consumption, Brompton (to reduce deficit on recent improvements)	800
Hospital for Epilepsy and Paralysis (towards extension)	350
Hospital for Sick Children (towards provision of wards for recovery cases at country branch)	700
Hospital of St. John and St. Elizabeth (towards enlargement of nurses' home)	800
Infants Hospital (towards extension)	750
Kensington, Fulham, and Chelsea General Hospital (towards extension)	1,250
King Edward Memorial Hospital (Ealing) (to reduce deficit on extension)	800
King George Hospital (to the building fund for the first stage of the new hospital)	10,000
King's College Hospital (towards improvements) ..	150
London Homœopathic Hospital (towards nurses' home extension)	600
London Jewish Hospital (to reduce deficit on acquisition of adjoining site)	100
London Lock Hospital (towards extension of out-patient department at Dean-street)	750
London Temperance Hospital (towards provision of new special departments and pay beds)	1,000
Marie Curie Hospital (towards provision of permanent out-patient accommodation)	100
Metropolitan Hospital (to reduce deficit on new nurses' home)	3,500
Middlesex Hospital (towards reconstruction)	14,000
Mildmay Memorial Hospital (towards extension of maternity pay block)	100
Miller General Hospital for South-East London (to reduce deficit on extension)	12,000
National Hospital for Diseases of the Heart (to reduce deficit on extension of out-patient department) ..	500
National Hospital, Queen-square (towards extension) ..	750
Nelson Hospital for Wimbledon, Merton, and District (towards provision of maternity pay-bed and child welfare block)	1,250
Plaistow Maternity Hospital (towards extension) ..	500
Poplar Hospital for Accidents (towards extension of X ray department)	150
Prince of Wales's General Hospital (towards provision of new out-patient department)	1,500
Princess Louise Kensington Hospital for Children (towards next stage of new hospital)	800
Queen Charlotte's Maternity Hospital (*towards* rebuilding and enlargement on new site)	9,000
Queen Mary's Hospital for the East End (to extinguish deficits on out-patient department and on maternity isolation block)	2,000
Royal Free Hospital (towards centenary extension scheme)	5,500
Royal Hospital (Richmond) (towards provision of new operating theatre)	300
Royal London Ophthalmic Hospital (towards provision of additional nurses' accommodation and wards) ..	750
Royal National Orthopædic Hospital (to reduce deficit on extension of country branch at Stanmore) ..	4,500
Royal Northern Hospital (towards provision of pay beds)	1,500
Royal Westminster Ophthalmic Hospital (to reduce deficit on rebuilding and enlargement on new site) ..	1,000
St. Bartholomew's Hospital (towards new operating theatres)	2,000
St. Luke's Hospital for Advanced Cases (to reduce deficit on new hospital)	100
St. Mark's Hospital (to reduce deficit on extension) ..	100
St. Mary's Hospital for Women and Children (Plaistow) (to reduce deficit on first stage of new out-patient department)	3,500
St. Peter's Hospital for Stone (towards extension) ..	400
St. Thomas's Babies' Hostel (towards provision of new out-patient department)	100
Seamen's Hospital Society (*see* Dreadnought Hospital)	
South-Eastern Hospital for Children (Sydenham) (towards provision of new casualty department and pay beds)	600
South London Hospital for Women (to reduce deficit on new out-patient department and nurses' quarters) ..	1,500
University College Hospital (towards extension of nurses' home)	750
Western Ophthalmic Hospital (towards rebuilding) ..	500
Westminster Hospital (towards provision of annexe for radium patients)	1,000
Willesden General Hospital (to reduce deficit on completed stages of extension)	750
Wimbledon Hospital (to reduce deficit on provision of children's wing)	500
Woolwich and District War Memorial Hospital (to reduce deficit on first stage of new hospital)	5,000
Total	£115,000

Voluntary Hospitals and the Local Government Act.

In the absence of the Vice-Chairman of the Voluntary Hospitals (Local Government Bill) Committee (the Rt. Hon. Hugh P. Macmillan, K.C.), Sir Edward Penton presented a report describing a draft scheme for a body representative of the Voluntary Hospitals of London to confer with the London County Council, under Section 13 of the Local Government Act.

The Voluntary System and the L.C.C.

The Chairman of the London County Council (Lord Monk Bretton) said that he thought the London County Council would welcome most cordially the coöperation of the Voluntary Hospitals of London in the extremely difficult and onerous duty of making adequate provision for the sick of London, and he was glad to be able to say that the draft scheme of representation *referred to had been approved by the* Central Public Health Committee of the Council, subject to one or two minor observations. It would, of course, in its final form be subject to the approval of the Council itself. It was the well-known policy of the Council for the last 20 years to do everything in its power to promote the welfare of the Voluntary Hospitals of London, and to seek their active coöperation in carrying out the various duties of the Council in connexion with the treatment of the sick. He believed that the County Council desired that the harmonious coöperation and happy relationship which had always existed between it and the Voluntary Hospitals should not only continue, but, if possible, should be still further extended, in the near future.

Sir William Collins trusted that the future of the voluntary system would be safeguarded, whatever might be the progress of municipalisation.

Hospitals and Motor Accidents.

Lord Ebbisham referred to the very important Bill before the House of Lords that day on which a proposal had been made which would be very helpful to the Voluntary Hospitals.

Lord Luke said that his amendment to the Motor Traffic Bill would provide that in the event of any patient being carried to a hospital, the hospital should receive recompense for curing that patient. At the present moment, in regard to more than nine-tenths of those who were taken to hospital, the hospital had to pay. If the amendment were added to the Bill, then in future the compulsory insurance would include up to £4 a week for the hospital for the out-of-pocket expenses, up to a maximum of £25. It would only cost the owner of a motor a premium of 5s. a year, and he should think the motorist would feel more comfortable if he held such a policy.

Arrangements for 1930.

The Prince of Wales said that Viscount Ullswater, whose wise advice the Fund would miss, had been compelled to discontinue his service on the Council owing to the pressure of his numerous duties. The Rev. Owen Spencer Watkins was being invited to serve in the place of the Rev. W. T. A. Barber, who had left London and was unable to continue his membership. There would be a change in the title of the Voluntary Hospitals (Local Government Bill) Committee which would now be called the Voluntary Hospitals (Parliamentary) Committee, thus enabling it to consider any other Bills that might affect hospitals. His Royal Highness also mentioned that during his forthcoming absence in South Africa he proposed to delegate his powers, as President, to a Committee consisting of the Lord Chancellor, the Speaker of the House of Commons, and the Governor of the Bank of England.

On the motion of Lord Donoughmore resolutions delegating powers to committees were passed, and the usual votes of thanks terminated the proceedings.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

School Health Administration.

THE Department of Health for Scotland and the Scottish Education Department have issued a joint memorandum on school health administration as affected by the new Local Government Act. This document, which is an excellent summary of the whole system of school health administration, is too condensed to be summarised further; but medical officers and school medical officers, as well as members of the new education committees, ought to make themselves familiar with every word of it. The new committees will be responsible for over 800,000 children—that is, roughly one-sixth of the whole population of Scotland—and the supervision of this large group continues during nine or ten of the most critical years of life. The school-child spends some 2000 days in the school environment, and the school health service has a long and unique opportunity for influencing the health and habits of the rising generation.

Proposed Clinic for Rheumatic Children in Edinburgh.

The public health committee of Edinburgh town council have agreed to recommend the establishment of a clinic for rheumatic children. Dr. William Robertson, the medical officer of health, suggests that a system of voluntary notification of rheumatism should be started, the notifying practitioner being invited to say whether hospital or other special treatment is required. The notification will give a rough indication of the incidence of early rheumatism—under which heading Dr. Robertson includes rheumatism, growing pains, chorea, St. Vitus's dance and pains in the joints accompanied by fever—and medical men will be invited to send patients for critical examination at the hands of an expert.

Dr. A. S. M. Macgregor, in his current bulletin on the health of Glasgow, says that November proved a favourable month. The general death-rate was 12·2, against 12·8 for November, 1928, and in one of the weeks it fell to 10·5, the lowest figure yet recorded for the month. Measles and pneumonia, though prevalent, showed a relatively low mortality, but a testing time for these diseases will come in January and February.

At the recent conference of the Scottish National Poultry Council, Mr. J. M. Caie, of the Department of Agriculture, sketched what has been done in arranging egg-laying tests during the last five years in Scotland. It has been found, he said, that the average number of eggs per bird of all breeds, and for the whole five years, ranged from 182 to 193. In 1908 there were just over 4,000,000 fowls in Scotland, and the average production of eggs per hen in that year was estimated at 72. In 1913 the number of eggs per hen in Scotland was given as 84, and in 1925, when the last census of production was taken, the estimate had risen to just over 100 eggs per hen per annum. These figures are not, of course, absolutely accurate; but they probably represent pretty fairly an actual increase in production.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Treatment of Drug Addicts in New York City.

WHEN Commissioner Richard C. Patterson, Jr., took charge of the New York City Department of Corrections in 1928, he found no uniform plan in operation for handling the 1500 drug addicts that come under the supervision of the department. A committee under the chairmanship at first of Dr. William R. Williams, and later of Dr. Alexander Lambert was appointed, and has issued its report.[1] Two major problems are dealt with in this report: (1) The problem of withdrawal of the drug in the shortest possible time; and (2) the ultimate rehabilitation of the addict. In a special ward at Bellevue Hospital, a number of different methods of withdrawal were studied. In order to have a standard on which to base results, it was agreed to use 100 patients in each method, and the symptoms selected as giving the best index of the condition of these patients on withdrawal were (1) gastro-intestinal symptoms; (2) muscular symptoms; (3) restlessness, both physical and mental; and (4) prostration, subjective and objective. Each of these symptom groups was recorded as absent, moderate, marked or excessive. Narcosan was first studied, and it was found to be no specific for drug addiction, nor to diminish the craving for narcotics after withdrawal. Withdrawal symptoms were influenced unfavourably, the gastro-intestinal symptoms being more severe than in abrupt withdrawal without any drug. Among other drugs tested were atropine, scopolamine, a number of depressants of the central nervous system (chloral hydrate, phenobarbital, paraldehyde, bromides), magnesium sulphate and iso-amylethyl barbiturate. The results in every case were unsatisfactory. The research was then turned to gradual withdrawal without substitute drugs. They find that "the reduction treatment, especially if carried out over a period of 14 days or more, is the most humane, in that it involves the least suffering. It is also the safest, as regards danger to life, and can be used in any case of drug addiction." They recommend that all addicts undergoing treatment be under capable medical supervision, that those whose general condition warrants it, be subjected to abrupt withdrawal, and that those not included in this class be given the reduction treatment.

---

[1] Jour. Amer. Med. Assoc., 1929, xciii., 1297.

It is recognised that after their release addicts will suffer again from the craving for the drug. The committee feels that much may be learned from past and present attempts at rehabilitation in New York, but that a new plan must evidently be developed to meet local conditions. Certain basic principles are laid down. The addict must learn a trade or line of work by which he may be self-supporting. A position must be found for him when he is ready for it. His progress for a number of years must be supervised, and he must be brought to a state of mind whereby he becomes coöperative and honestly desires to be permanently free of his habit. They dwell also on the importance of making careful choice in the personnel and location of the centre, and in its equipment. Some arrangement must also be made whereby the addicts will not be free agents until finally discharged.

Consumption of Water.

The average daily consumption of water in 58 cities of Great Britain is said to vary from 17 to 84 U.S.A. gallons per capita. In most American cities the consumption exceeds 100 gallons per capita, though in some cities, such as San Francisco, where the water supply is metered, the consumption does not greatly exceed 70 gallons. Why do we use so much more water than Europeans? This question is discussed in a recent paper by Mr. Abel Wolman, the editor of the *Journal of the American Water Works Association.* He believes that only a part of our excess consumption is to be attributed to waste, and to the greater availability of sources. Much, he thinks, must be due to the greater demand in this country for sanitary conveniences. The sale of bath tubs here increased, it appears, from 415,400 in 1919, to 1,101,000 in 1927, in which period the population increased by only 15 per cent. Whether or not the use of so many bath tubs should be considered wasteful Mr. Wolman admits may be a matter of opinion. In Beverley Hills, California, the per capita consumption is over 400 gallons, although the water is metered. The residents are wealthy, and indulge in private swimming pools, as well as numerous bath-rooms in their luxurious homes. Does this spell "waste" or "a higher standard of living"?

Drug Stores and Venereal Disease.

The corner drug store, so-called because almost every street corner can boast of at least one of them, is a shop where you may buy ice-cream, "soft" drinks, newspapers, tobacco and many other things besides drugs. But like his English equivalent, the chemist, an American drug-store clerk is not unwilling to offer also medical advice for which he makes no charge, and the people seem ready enough to accept his recommendations. Thus an investigator for the American Social Hygiene Association who asked 100 young men, selected at random in public places, where he might get advice for venereal disease, was advised by no less than 42 to get it at a drug-store. Twenty-four directed him to a physician, 10 to a clinic, four offered home remedies, and 14 withheld advice. A questionaire was sent to all druggists in this same city, asking how many applicants they had for venereal disease advice. Replies were received from 237, who between them acknowledged 2355 applications from alleged venereal disease patients for advice, remedy without a physician's prescription, or treatment. One-third of the druggists admitted giving treatment to such patients without prescriptions. Forty-four per cent. had suggested that the patient go to a clinic or to a physician, while 23 per cent. did not state what their advice had been.

Blood Calcium.

The importance of maintaining blood calcium at the normal level is brought out in two recent reports. Drs. E. V. McCollum and Henry Klein, of the Johns Hopkins School of Hygiene, have conducted a series of experiments on pigs with diets of varying calcium content. These animals were selected on account of their omnivorous habits, because of the comparatively long suckling period, and because they have two sets of teeth. Three types of diet were offered to three groups of pigs, one of normal calcium content and one each of subnormal and high calcium content. Although the diet deficient in calcium was softer than the other diets, the teeth of pigs eating this diet were rapidly worn down to the gum margin. The teeth grew more slowly, and were less calcified (as shown by X rays) than those of the controls. Malpositions were about three times as common. Malocclusion was found to be characteristic of pigs that had an inadequate calcium allowance during the first year and adequate calcium thereafter. The experiments were carried out under a grant from the Research Committee of the American Dental Association. At the same time, Dr. Walter Timme, of the Neurological Institute, announces that parathyroid deficiency, leading to abnormally low blood calcium, has very definite influence on behaviour. Patients with hypoparathyroidism are prone to sudden anger on very slight provocation, and are unadaptable and uncompromising. They constitute problem cases in the home, at school and in every environment where they may be found. Their behaviour eccentricities may indeed become so extreme as to lead to certification.

Medical Service by Easy Payments.

A private corporation has offered one solution for the problem of the high cost of medical care. It has been chartered in California with the avowed object of applying the instalment system to the purchase of medical and dental service. If a patient needs operative treatment, the company will take care of the charges under contract for repayment over a specified period of time.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

The Yellow Peril.

AMONGST many tribulations India has much to be thankful for in the immunity she has so far enjoyed from certain tropical diseases which might have been expected to find easy entry. Jigger, for example, never seems to have obtained a real hold, though sufferers from the disease must continually be arriving from East Africa. The outstanding instance is, of course, the importation of yellow fever, a danger which has been much increased by the development of air travel. In a recent number of the *Indian Medical Gazette* the Surgeon-General of Madras commenting on the situation made good two points. One is that the Indian stegomyia, *Aëdes ægypti*, is capable of conveying the infection; the other that a person who has been infected in West Africa may cross the Indian frontier by air before the infective stage of the disease has been reached. It would be quite possible for an attack of yellow fever to escape recognition by being mistaken for influenza or febricula, and if such an unrecognised case were introduced to a place where suitable mosquito vectors exist no ordinary precautions could prevent the rapid extension of the disease. Dengue, says the Surgeon-General, is known to spread like wildfire when infection occurs amongst a susceptible population, and as yellow fever is carried in exactly the same manner it is reasonable to believe that an outbreak would speedily grow beyond control. Under these circumstances, he argues, we have to choose between the comparatively slight inconvenience which would be caused by interference with air traffic between West Africa and the eastern countries and the appalling results which might follow the spread of yellow fever to India and the Far East. It is satisfactory to know that the Public Health Commissioner, the Government of India, and the Secretary of State are alive to the danger, and that international regulations are likely to be framed to meet it.

Jail Reports.

One Indian jail report is very like another, and that which furnishes a text for these remarks is no exception to the rule. There is much in it to justify a feeling of pride in the department. It is common knowledge that the general arrangements in the jails are excellent, the housing is up to date and adequate, the food sound and plentiful, and even if there is technically some overcrowding, the normal scale is so ample that it is not likely to have an injurious effect. The general health of the inmates is good; the mortality of 8·6 per 1000 is far below that of the population outside the walls. A great majority of the discharged prisoners show an increase in weight, and no doubt many of them carry away something more on the credit side, having been taught a trade. What, then, it may be asked could be further desired? The answer is to be found in a chapter headed "Educative, Moral and Religious Influences in Prisons" of Sir Evelyn Ruggles Brise's "The English Prison System" (1921). In British prisons books of a moral and instructional character are issued freely to all who can make use of them, lectures are given, and discussions take place on subjects chosen by the prisoners themselves. A summary of current news is read out weekly. Daily religious services are made attractive by the aid of music. Music is also offered in the form of entertainments by choral societies, and in a large American prison musical training has long been given to convicts, with the result that many of the men were able to earn a livelihood after discharge, and the percentage of relapse to crime was definitely lowered. Surely the time has arrived when every Indian provincial prison return should have a heading for educative, moral, and religious influences, and show some substantial progress under it every year. Assistance to discharged prisoners is another direction to which philanthropic effort might be usefully directed.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg.-Lt. R. M. Buchanan to be Surg.-Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. J. W. C. Stubbs is secd. for serv. under the Colonial Office.

Capt. B. C. W. Pasco relinquishes his temp. commn. and retains the rank of Capt.

ARMY DENTAL CORPS.

Lt. A. F. D. Shapland, temp. Dental Surg., Gen. List, to be Lt. (on prob.).

TERRITORIAL ARMY.

Maj. H. E. McCready to be Lt.-Col. and to comd. the 143rd (S. Midland) Fd. Amb., vice Lt.-Col. (Bt. Col.) H. F. Humphreys, vacated.

Lt. F. W. Crook (late 5th Bn. K.R.R.C., Spec. Res.) to be Lt.

ROYAL AIR FORCE.

W. J. Cotter is granted a temporary commission as a Flying Officer.

Flying Officer B. A. Porritt is transferred to the Reserve, Class Di.

BRITISH HOSPITAL FOR MOTHERS AND BABIES.—Princess Mary recently opened a new administrative block and clinic department of this Woolwich Hospital, which has been built at a cost of £40,000.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1928 statistics of seven English administrative counties, the island of Guernsey, and of the "landward" or extraburghal areas of two Scottish counties:—

Name of district and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Durham (949,300)* ..	21·1	11·5	1·01	1·01	2·2	1·4	80	37	5·5
Staffordshire.. (712,080)*	19·2	10·5	0·73	1·19	1·6	1·3	62	—	3·6

* Adjusted for alteration of boundaries during the year.

† Standardised—Guernsey 9·9, Dumfries 12·0.

Relation of stillbirths to live births: Durham, 2·8 per cent.; Huntingdonshire, 3·0 per cent.; Rutland, 2·7 per cent. Guernsey, 3·6 per cent.

Durham County.

Dr. T. Eustace Hill says that the infant mortality-rate is the lowest ever recorded in the county. As an unsatisfactory feature of 1928, he notes the very marked reduction in the number of new dwellings available for a population over 30 per cent. of which is overcrowded. The much needed substitution of water-closets for privies has not made satisfactory progress, possibly owing to the prevalent trade depression. The prevalence of small-pox was less, 1124 notifications with 3 deaths, as compared with 5111 cases and 19 deaths in 1927. The notifications of encephalitis lethargica numbered 21, and the deaths 33. There were 180 notifications of puerperal fever and pyrexia with 9 deaths, whilst the deaths from other accidents and diseases of pregnancy and parturition numbered 103. This low proportion of maternal deaths due to sepsis was somewhat increased by the investigation of 88 maternal deaths. The principal causes of these investigated deaths were:—puerperal sepsis, 13; eclampsia, 16; embolism, 9; toxæmia, 7; postpartum hæmorrhage, 5; and antipartum hæmorrhage, 10. The notified cases of ophthalmia neonatorum numbered 140, and all cases of inflammation of the eyes of new-born children were followed up by the health visitors. The damage done to survivors from ophthalmia was one case of total blindness and another of impaired sight in one eye. Of the 563 stillbirths, 535 were legitimate and 28 illegitimate; 149 occurred in a first pregnancy; 1 in a twenty-third; 1 in a twentieth; 3 in a sixteenth; 1 in a fifteenth; and 3 in a fourteenth. The total pregnancies of these 563 mothers was 2453, of which 735 resulted in stillbirths. Among the stillbirths there were 30 sets of twins, including one of joined twins.

During the year a progressively increasing number of cases of skin tubercle (chiefly lupus, some scrofuloderma, and a few cases of tuberculosis cutis verrucosa) were sent to the skin department of the Newcastle Infirmary for ultra-violet therapy. Sir Robert Bolam says the most striking feature of the treatment is the disappearance of unsightly lesions attendant upon secondary pus infection, enabling the patient to go about with less physical and mental discomfort, but he finds that exposure to ultra-violet rays is not by itself sufficient to eradicate tuberculous lesions of the skin, but needs to be combined with other methods. Cases are also sent to Newcastle for radiographic examination by Dr. H. E. Gamlen, and considerable use was made of radiography in the oblique position of the thorax as an aid to the diagnosis of enlarged tuberculous glands in the mediastinum. The high death-rate from tuberculosis in Jarrow is the subject of a special investigation, the death-rate in 1928 from lung tuberculosis being 1·29 and from all forms 1·65. Young adults suffer in particular, and in many the disease tends to produce scattered foci with rapid caseation, and to terminate fatally after a short illness in spite of sanatorium or other treatment. This type of lung tubercle is met elsewhere on Tyneside and in other parts of the county, and resembles the acute type met with in races which have developed no immunity.

There is still much room for improvement in the effluents from collieries and by-product works. The department of scientific and industrial research held a conference of interested authorities and industries in October with regard to a proposed thorough biological survey of the river Tees, which was to be the first of its kind. The local representatives objected to being saddled with the cost of an investigation which was admitted to be one of national importance.

Staffordshire.

Dr. W. D. Carruthers includes in his report many details as to improvements and deficiencies in the water-supplies, sewage disposal works, and housing conditions of the 20 urban and 18 rural districts which make up the administrative county. The new houses built in 1928 were 2488, compared with 4210 in 1927. The local authorities built 1360, as compared with 2613 in 1927. However, at the end of the year there were 1480 houses in course of erection, compared with 210 in 1927. Much overcrowding still exists, and until it is possible to construct houses at lower rentals overcrowding, unhealthy areas, and slum dwellings cannot be dealt with in any drastic fashion. The systematic examination of milk samples for tubercle began in March, and during the first year 88, or about 6 per cent. of 1340 samples were found to be tuberculous. Eighty-two outside complaints of tuberculous milk produced in the county were received, and as a result 48 animals were slaughtered under the Tuberculosis Order. In addition, two cows had died and seven been disposed of by the owners for slaughter. Staffordshire made 18 complaints of tuberculous milk sent in to the county from outside, but the investigation by the outside authorities had a negative result in nine instances. The county began the year with one farm licensed for Certified milk, and three licensed for Grade A (T.T.), and ended the year with six licences for Grade A (T.T.), the Certified milk licence having been relinquished. Samples of all graded milks, including Grade A, were examined every month. Of 607 such samples, 526 were satisfactory, 72 not satisfactory, and 4 contained tubercle bacilli. It is not mentioned whether the tubercle bacilli were confined to Grade A milk or indicated a failure to maintain a tuberculin-tested herd tubercle free.

Both the death-rate from all causes and the infant mortality-rate were the lowest ever recorded in the county. There were 150 notifications of small-pox and one case in an old man proved fatal. There was an increase in diphtheria, chiefly in urban districts; the cases numbered 973 and the deaths 60. In some of the most affected southern districts immunisation work was arranged for in 1929. Of 23 cases of encephalitis lethargica, 21 ended fatally. There were 188 notifications of dysentery in the rural districts, 136 being at two mental hospitals. In one of the mental hospitals, which suffered simultaneously from an outbreak of typhoid fever (17 cases), there were 101 cases of dysentery, and the specimens examined showed that the causal organism was the Flexner bacillus. The new cases of venereal disease treated at the clinics were about the same as in the previous year, but the attendances were considerably better, and the defaulting was less. The confinements attended by midwives numbered 10,523, being 76·5 per cent. of the total births. The midwives notified 208 stillbirths (i.e., 2 per cent.) in their practices, and sent for medical help in 26 per cent. of their cases.

Cheshire.

Dr. Meredith Young reports among the features of *the county tuberculosis scheme:—a slight increase* in the number of notifications and deaths; a large increase in the attendances at orthopædic clinics, owing to the fact that the after-care scheme is now functioning throughout the country; the attendances at hospitals for special treatment were doubled, largely owing to the increase in artificial sunlight treatment; and a specially gratifying feature was the larger number of consultations between practitioners and tuberculosis officers. The bona fide midwives, who numbered 226 when the county took over inspection, are now only 37, and with the passing of the old-fashioned midwife many old superstitions associated with childbirth also pass, says Dr. Young. There are still nine midwives who cannot take the temperature or pulse. The new midwives do not receive adequate remuneration. The county council subsidise five midwives in districts where they cannot make a living. Four receive £60 and one £80 in addition to the fees they earn. A grant is made to two midwives annually towards attendance at a month's refresher course at Plaistow Maternity Hospital. In the 30 registered maternity homes there were 363 births, 18 of which were stillbirths. Of these births, 118 occurred in Bromborough Pool Home. There are still a number of unnotified births, knowledge of which is only obtained through the registrars. Investigation showed that at the end of the sixth month 65 per cent. of the mothers in rural districts were breast-feeding and 61 per cent. of those in urban districts. The illegitimate births numbered 368, of whom 39 died—an infant mortality-rate of 106. An inquiry into the circumstances of 114 illegitimate infants showed that the conditions were quite satisfactory in 103, fairly satisfactory in 9, and unsatisfactory in 2 cases. Towards the end of 1928 the first antenatal clinics were arranged for, under the care of obstetrical specialists, at Congleton, Runcorn, and Sale respectively, to begin work in 1929. Expectant mothers from the surrounding district have also been enabled to attend the antenatal clinic at Ashton-under-Lyne Infirmary.

Increased interest, Dr. Young states, is being manifested by the dairy industry in the purity of milk. The experience of Manchester and Salford, however, is that a larger percentage of tuberculous milks come from Cheshire than from other counties. Dr. Young mentions that as the result of outside complaints of tuberculous milk 152 tuberculous cows were slaughtered. There is a good deal of slackness shown by local authorities, both as to the removal of refuse and the management of tips. There is much variation in water-supplies—thus in Nantwich R.D. there are no fewer than 18 townships with no public water-supply, whereas Northwich R.D. is carrying out its water-supply duties "in a highly laudable fashion." The appointment of a new sanitary officer has led to an improvement in sewage disposal and the prevention of rivers pollution. Dr. Young hopes that all the authorities concerned will support the county council's scheme for a joint committee to deal with the pollution of the river Dee.

Hampshire.

Dr. W. J. Hart, acting county medical officer, describes the arrangements for maternity beds. An antenatal clinic is held bi-monthly at the Royal Hants Hospital, by means of which abnormal cases are booked for the hospital and normal cases for the maternity home managed by the Winchester Maternity Society, and subsidised by the county council. During 1928, 130 cases were admitted to the hospital and 157 to the home. In addition, 31 county cases were admitted to ten other hospitals and homes. The net cost to the county council for these 318 patients was £7 per case. The M. & C. W. centres now number 100, and are managed by a body of 550 voluntary workers. The county council's contribution to the expenses of these centres is £600 a year. Arrangements have been made for the establishment of 14 antenatal clinics. The clinic at Basingstoke will be under the charge of a practitioner with considerable obstetric experience, but the obstetric qualifications of the medical officers of the other 13 clinics are not mentioned. For the purpose of the puerperal fever, &c., regulations, 12 consultants have been appointed, and during the year this facility was utilised in 13 instances. Midwives attended 76 per cent. of the 7818 births, and more than half of their patients paid the insurance fee of 5s. per case to cover the expense of medical aid. For the 2087 insured women a doctor was called in in 48 per cent. and the net cost to the county council was £1100; for the 2724 uninsured women a doctor was summoned in 20 per cent. and the net cost to the council was £585.

The Hants County Council decided not to delegate their powers under the Nursing Homes Registration Act, and in response to applications registered 25 premises. There are still isolated districts without midwives, and the county council undertakes the refund of the expenditure up to £600 a year of the County Nursing Association in providing for these districts. The Nursing Association during last year only spent £118 in this extension of service. In Hampshire it is not found advantageous for district nurses to act as school nurses, tuberculosis nurses, or health visitors. Owing to the unreasonable delay in the notification of tuberculosis an arrangement was made in June for the registrars to report deaths from tuberculosis as they occurred. During the rest of the year the registrars reported 136 deaths, and of these 50 had not been notified! The 71 county council shelters are well used and appreciated. The sanatorium at Chandler's Ford has been fully occupied by 26 women and 20 children, and the sanatorium at The Mount, Bishopstoke, with 72 beds, gradually filled with suitable cases, and has been fully occupied since January, 1929.

Cumberland.

Dr. F. H. Morison reports that he has been instructed to draw up a complete antenatal scheme, and as a preliminary he gives statistical information to show that maternal mortality is higher in Cumberland than most counties, and has progressively increased both in the urban and rural districts during the last three quinquennia. Since the Housing (Rural Workers) Act, 1926, came into force, applications have been received for 94 dwellings, and sanctioned in 93. In the case of 14 the applications were withdrawn and, at the time of writing the report, £1403 had been paid in grants and £50 as a loan. Owing to the heavy incidence of diphtheria in the Brampton rural area immunisation was extensively carried out in 1926, and no cases of diphtheria were notified there in 1928. Notification of puerperal fever was not satisfactorily carried out. There were five notifications and six deaths, and five of the six fatal cases were unnotified. Dr. Morison also complains bitterly of the imperfect notification of tuberculosis. During the last three years 65 per cent., 61 per cent., and 65 per cent. of the deaths from tuberculosis were notified less than six months before deaths, or not notified at all. The accommodation for the two V.D. clinics at the Cumberland and Whitehaven hospitals is reported to be unsatisfactory in several respects.

Huntingdonshire.

Dr. C. B. Moss-Blundell reports that the towns have adequate supplies of good water, with the exception of Godmanchester, and that "the rest of the county derives its water from wells and ponds, all of which are 'shallow' and the water of which is grossly polluted." The water-supply of schools is similar to that of the area in which they are situated. No action has been taken to check pollution of rivers and streams, and very little action with regard to the adulteration of foods and drugs. There were ten cases of small-pox, all in the neighbourhood of Peterborough where this disease was prevalent. Isolation hospital accommodation is quite inadequate, and the whole situation requires revision. Of the 954 births registered 225 were notified by midwives, 3 by parents and handy women, 704 by doctors, and 22 by registrars only. There were 28 stillbirths, equivalent to 3·0 per cent. of the live births. The county health visitors and the district nurses visit expectant mothers but there are no antenatal clinics.

Rutland.

Dr. Christopher Rolleston reports that the village of Ketton, "the pride of Rutland," is to be invaded by large cement works, which, however, will employ 100 men and are not likely to pollute the atmosphere. Electrification and possibly industrialisation of the whole county is foreshadowed. Owing to the smallness of the figures the statistics fluctuate much from year to year. Rutland had the lowest still-birth-rate among the counties, Lancashire and Cheshire the highest. Over a period of years Rutland has a low maternal mortality, but during 1928 two deaths from sepsis in the Oakham R.D. gave a maternal mortality of 7·6, the highest among the English counties. Dr. Rolleston urges the establishment of antenatal centres. Of 11 illegitimate children three died, an infant mortality-rate of 272·7. The county council subsidises a considerable number of approved nursing associations. The schemes for dealing with tuberculosis and mental deficiency compare very favourably with those of other counties. The 30 new houses included 16 erected by local authorities and 9 subsidised houses by other enterprise. Dr. Rolleston thinks that the benefits of the Housing (Rural Workers) Act, 1926, are not sufficiently known. Nevertheless, during last year, grants were agreed to for nine houses and refused for four, so that as much progress has been made in Rutland as elsewhere. Three veterinary surgeons have inspected the dairy herds, and one cow was condemned for tuberculosis. In addition, the inspection of a herd, as the result of an outside complaint, resulted in the biological examination of the milk of seven individual cows, four of which contained tubercle bacilli.

Guernsey.

This isolated community has points of special interest to the epidemiologist. Thus, the cows are free from tubercle, and there ought to be no human tubercle from that source. The three deaths from non-pulmonary tubercle in 1928 were from meningitis (aged 2–5), from peritonitis (aged 5–15), and from tuberculosis of the kidney (aged 25–65), respectively. The two chief industries are the culture of fruit and vegetables and granite quarrying. If the ingestion of tuberculous milk in childhood (as some believe) prevents tuberculosis of the human type, Guernsey should be badly off but, on the other hand, it has to be considered that granite quarrying and cutting has a phthisigenic effect, that the fruit and vegetables are chiefly grown under glass (hardly a healthy form of gardening!), that Guernsey has its housing question, 23 "terribly insanitary houses" being demolished in 1928, and that persons stricken with consumption may take up their residence in Guernsey owing to its reputation as a health resort, and that all these causes may help to keep up the death-rate from pulmonary tuberculosis, rather than the lack of immunisation by tuberculous milk. Dr. H. Draper Bishop reports that the cases of diphtheria were of a severe type, with a case fatality of about 10 per cent., and that most of the 18 cases of scarlet fever were also of a severe character. For many years previously scarlet fever had been practically unknown, with the exception of 1926, when a small outbreak occurred as the result of a fatal but unrecognised case being landed from a ship. An elderly man and his wife were notified as suffering from encephalitis lethargica and both died. Guernsey has had a law for the prevention of smoke since 1858. Recently the smoke nuisance has been increasing. A successful prosecution was undertaken against one firm in 1928, and as a result all the firms are installing appliances to prevent smoke. Better methods for the collection and disposal of refuse are under consideration. Dr. Bishop suggests that a scheme should be devised to enable sufferers from cancer to be sent to England for radium treatment.

Fife.

Dr. G. Pratt Yule says the infant mortality-rates of the four county districts were: St. Andrews, 81; *Dunfermline, 80; Cupar, 88; and Kirkcaldy, 93.* Dunfermline and Kirkcaldy include coal-mining areas and were the most likely to be affected by the aftermath of the mining trade crisis of 1926. There was no death from typhoid fever in 1928 and only one in 1927, although this disease was formerly common in Fife. Dr. Yule attributes its decline to better water-supplies and improved conveniences. The tuberculosis scheme embraces 20 burghs and a population of over 200,000. The scheme is unusual in that there are no dispensaries, and the work is done by home visitation. During the year the notification of new cases has been satisfactory, and medical practitioners have coöperated cordially. Most of the new cases come from the smaller unhealthy dwellings. The accommodation at the V.D. centres at Kirkcaldy and Dundee has been improved, but the premises at the Dunfermline centre are "most unsuitable and inadequate." Centres have not hitherto been established for the M. & C.W. scheme. Dr. Yule points out that these will be necessary if progress is to be made in prenatal and postnatal work for mothers, and in the care of pre-school children. The 13 childbirth deaths gave a mortality of 6·1 per thousand births, and in the three previous quinquennia the annual deaths were 14, 18, and 18 respectively. Efficient antenatal supervision, maternity beds for cases from unsuitable homes, and the early removal to hospital of cases with puerperal morbidity are given by Dr. Yule as some of the remedies for this high death-rate. Housing efforts in the Dunfermline and Kirkcaldy districts have hitherto been chiefly concerned *with the mining areas, but Dr. Yule points out* that much might be done profitably under the Rural Workers Act of 1926 for the improvement of the stone-built rural cottages, which are structurally substantial, but in their present condition hopelessly insanitary. The dairy cattle undergo veterinary inspection twice a year, and 42 cows with tuberculosis of the udder were discovered. Certified milk is produced at two farms, and Grade A (T.T.) at one.

Dumfries County.

Dr. John Ritchie renews his *plea for hospital beds* for puerperal fever. Two dairy farms were licensed for Certified milk and 12 for Grade A (T.T.). One licence was revoked, owing to the farmer refusing to remove from his herd 10 cows which had reacted to the tuberculin test during the summer. A clean milk competition attracted 22 entrants. The competition lasted from Feb. 15th to May 10th, and three surprise visits were paid to each competitor. At the end of each round a competitor was notified of his marks and the standard, high to begin with, improved during the competition. The county veterinary *inspectors,* Messrs. F. A. Davidson and G. A. Sangster, submit a very interesting report on milk production in the county. The district committees adopted by-laws in 1926, and since then the veterinary surgeons have been laying the foundations for improved methods and premises. There are 881 dairy farms housing 14,024 *cows. Attention is drawn to a prevalent* type of mastitis associated with a diplococcus. This type of the disease is of a chronic and mild nature, and unlike ordinary streptococcal mastitis the acidity of the milk from the affected quarter is low. Infectious abortion is reported to be on the increase and "probably as big a scourge to the dairy farmer as tuberculosis." The veterinary inspectors further state that the supply of milk from tubercle-free herds has been in excess of the demand for some time. Their experience leads them to emphasise two important factors in the maintenance of tubercle-free herds. First, it is practically impossible to maintain such a herd unless it is isolated from untested stock, either by natural barriers or double fencing; secondly, the incubation period may last months, so that a newly purchased cow may pass the test, be added to the herd, and subsequently develop tuberculosis. They, however, affirm their strong belief in the reliability of the tuberculin test.

SCHOOL MEDICAL SERVICE.

—	No. on roll.	Aver. E.S. attendance.	Routine inspections.	Special exams. and reinspections.	Percentage of defects.
Blackburn ..	10,433	14,489	4,526*	8,961	20·3
Smethwick ..	11,683	11,538	4,521	9,087	23·2

E.S. = Elementary school.

* With 1114 of 11 to 12 year groups equals 5640.

Blackburn.

THE report of Dr. V. T. Thierens, in succession to Dr. Holden, has coördination and continuity as its keynotes. The school medical officer and assistant are also medical officer of health and assistant, while the tuberculosis officer and the woman assistant medical officer also help in the school work. Record cards are transferred from the child welfare centre to the school medical service. For young children nursery classes have just been opened, whose main aim is to cultivate good habits in the widest sense. An important feature is the afternoon siesta, when for 45 minutes the babies sleep on bed rests which they fix up themselves. Milk and cocoa are supplied at a charge of a halfpenny a day, or in exceptional cases gratuitously. The medical inspection is carried through by frequent visits from the nurse, with whose help it is hoped to eliminate many of those minor defects which retard educational and physical progress in later life. Those who fear nervous or mental strain from sending babies to school should study a typical time-table which includes handkerchief inspection, nature chat, preparation for lunch, play and music, with sleep time in the afternoon. In Blackburn there are 1300 children under five attending school, and Dr. Thierens submits the need for extension and special class-rooms built on the open-air principle, with slipper-baths and gardening facilities.

During ordinary school life the *children of Blackburn* receive close medical attention, with an extra age-group for medical inspection at 11–12, and special supervision is exercised over the rheumatic children. The establishment of a rheumatic supervisory centre is suggested to link up the work of the school medical service, the after-care committee, and the certifying factory surgeon. For many of the defects left over on leaving school treatment is ensured by coöperation between the service and the juvenile employment committee. Mr. Duckworth, who serves the educa*tion committee as juvenile employment officer,* gives 31 examples of untreated defects in about half of which his efforts secured attention. There is still the question of defects arising after school age, but the decision to raise the leaving age to 15 will halve the gap before the care of the Insurance Acts is reached.

Smethwick.

Dr. Hugh Paul gives a thorough consideration to the influence of Vita glass. His experiments point to a definite increase in the hæmoglobin content of the blood of the children who worked in class-rooms so glazed, but their heights and weights showed no superiority, *nor did educational tests detect any* influence. In his opinion the experiments would not justify the education committee in reglazing all the old schools. Of the great value of sunshine in the open-air he is keenly aware; an open-air school on the Fors Estate site, to be ready for pupils by May, 1929, will compare favourably, he writes, with the best in the country. He puts in a plea for more open spaces for children to play in; the street playgrounds of the past are now unsafe and other spaces should be provided within easy reach of the home. One new recreation ground has been provided through the generosity of Messrs. Guest, Keen, and Nettlefold. Dr. Paul suggests that future housing schemes should set apart small areas for recreation purposes.

The education committee have no orthopædic scheme, nor any special school of their own, but Smethwick Cripples Union, a voluntary body, works in close harmony with the school medical service, which refers to it cases of crippling defect. The union employs an orthopædic surgeon, Mr. Wilson Stuart, and a full-time masseuse and orthopædic nurse, and their clinic is equipped with an ultra-violet installation. Children requiring in-patient treatment are sent to Northfield or Bromsgrove, where the most modern methods are available. Pulmonary tuberculosis is dealt with at the chest clinic, where 108 cases were under observation, though only one child was found definitely suffering from phthisis. The only note of regret in the report concerns the large amount of uncleanliness (9·9 per cent.) in the borough; in the year 1928 no child, Dr. Paul writes, ought to come to school dirty. The number of cleanliness examinations was increased from 32,000 in 1927 to 43,000 in 1928; it is, he remarks, primarily the duty of parents to keep their children clean, and in a town like Smethwick where they take more than an average interest in the medical inspections it is astonishing to find so many dirty children; 18 of the cases reported were in the secondary school. The trouble should yield to the influence of the nursery school which is hoped for, and which should also prevent the large percentage (26·4) of medical defects among school entrants.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 14TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 265; scarlet fever, 3157; diphtheria, 1749; enteric fever, 31; pneumonia, 985; puerperal fever, 57; puerperal pyrexia, 100; cerebro-spinal fever, 11; acute polio-myelitis, 8; acute polio-encephalitis, 2; encephalitis lethargica, 13; dysentery, 8; ophthalmia neonatorum, 87. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Dec. 17th–18th was as follows: Small-pox, 379 under treatment, 8 under observation (last week 363 and 15 respectively); scarlet fever, 2715; diphtheria, 2680; enteric fever, 64; measles, 540; whooping-cough, 122; puerperal fever, 19 (plus 8 babies); encephalitis lethargica, 123; poliomyelitis, 3; "other diseases," 11. At St. Margaret's Hospital there were 13 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 27 (13) from measles, 8 (2) from scarlet fever, 19 (1) from whooping-cough, 57(16) from diphtheria, 54 (12) from diarrhœa and enteritis under two years, and 44(3) from influenza. The figures in parentheses are those for London itself.

The death from enteric fever outside London was reported from Chesterfield. Wigan reported 4 deaths from measles, Stoke-on-Trent 3. Three deaths from whooping-cough were reported each from Birmingham, Leeds, and Sheffield Diphtheria claimed 4 deaths in Hull; diarrhœa 6 deaths in Liverpool, and 3 each in Nottingham, Manchester, and Salford. Influenza claimed 5 deaths in Sheffield.

The number of stillbirths notified during the week was 227 (corresponding to a rate of 38 per 1000 births), including 32 in London.

"Audi alteram partem."

THE APPROACHING CHANGES IN THE HOSPITAL SYSTEM IN THIS COUNTRY.

To the Editor of THE LANCET.

SIR,—The inadequacy of the provision for institutional treatment of the injured and sick of the working classes has been a sad spectacle in this country ever since the means at the disposal of doctors for better treatment became appreciable. It has been reported that there are 5000 potential patients on the waiting-list for admission into the Royal Infirmary, Edinburgh, an institution that meets, and is expected to meet, the needs of only a small section of the population. The disparity between the capacity of such hospitals and the needs of the people has rapidly increased, is still on the increase, and, indeed, is likely to increase further, and at a greater speed. Treatment of fractures, for example, was, even 30 years ago, in the main domiciliary, and that for pneumonia and typhoid was also the same; to-day each of these conditions needs the facilities of an adequately equipped institution to provide the advantages to which it is now realised every patient is entitled. In former days the charity hospitals, as I will term them here, did all they could to meet the needs of the poor, and the medical profession responded by giving their services on conditions acceptable and honourable to all concerned. The chief hospitals, maintained on a charity basis, have medical schools which are the pride of the country. The subsidiary ones have served the community and the doctors in a way that is reflected in each locality. Of late years it has been thought desirable to re-christen all these hospitals—those with and without medical schools—"voluntary" in replacement of the time-honoured "charity." The motive for that change in name is not apparent; but it in no way disguises the real nature of the hospitals, but only gives a pretence where none is necessary. Unfortunately, it has been impressed upon the public that these hospitals, whether with and without medical schools, are incomparably superior to others in this country and outside it. The directions in which they once occupied that proud position were especially: in being spaciously constructed and staffed competently by nurses. But the world has caught us up in these and many other directions and our hospitals have been outstripped.

Our machinery for providing institutional treatment for the workman under the Insurance Act is dependent upon charity, with a recent addition on the pseudo-provident system worthily supported by many working men and women. Owing to a stationary state in medicine there was until recent years no greater need for institutional treatment than could be met by the large charity hospitals, because the technical means for the care of accidents and of disease were not then as fully appreciated as they are at present.

But to-day, under totally new circumstances and conditions, the technical treatment of accidents and diseases demands a great increase in the facilities for institutional treatment. Charity and pseudo-provident schemes in these times are totally inadequate for such a purpose. The hospitals, with medical schools attached, need to be greatly increased in numbers rather than in size if medical education is to be promoted as it should be and has been until recent years in this country. Book-learning is excellent, but without technical training it is next to useless and often dangerous. As a direct consequence of the policy, or rather lack of a policy, of the General Medical Council in regard to the education and training of the doctor a young man is qualified by an examining body registered by the State to practise medicine in all its branches when he has often had insufficient clinical experience.

Not only is the young doctor inadequately trained for the professional work in front of him but there is, in this country, no separate hospital provision for the training of physicians, of surgeons, of obstetricians, and other specialists to prepare the best graduates for the higher work they should undertake. Indeed, these exceptional men are now neglected, and their neglect will assuredly react to the detriment of the science and art of medicine.

The system for the poor-law hospitals or infirmaries, still in being, was originally planned to provide institutions for the treatment of the working people throughout the country, and an adequate machinery was created for the purpose. But in consequence of the rapid development of industrial prosperity during the nineteenth century the charity hospital was considered more in keeping with the sentiments of the age. Quickly hospitals, supported by the charitable, *made their appearance throughout the* country in growing centres of population. Recently these hospitals have been in great part brought under the support of a pseudo-provident system which the working men have evolved to a remarkable degree of perfection. Charity has, therefore, been assisted by a pseudo rather than a true provident system, with the approval of the working men. The hospitals in existence to-day, then, are the charity hospitals with and without medical schools attached, and these are regarded as the proper institutions for the working-classes. Unfortunately they are not large nor numerous enough to meet the needs of those classes in the community. Besides there are the hospitals under the poor-law, which have of recent years been greatly extended, to serve the dense populations of the big cities and towns. The last far outnumber the first group and all together fall far below the needs of the community since the progress that has been made in *medical science* during the last 50 years.

Especially more hospitals with medical schools for the technical training of young doctors are urgently needed; also more for the institutional treatment of the working men and their families; and, at the moment, more urgent still is the need for hospitals in which future physicians, surgeons, obstetricians, and other specialists can be adequately trained. Although no coherent scheme has been put forward for meeting the hospital needs of the present nor of the future, the situation fortunately is in a plastic state. The great hospitals with medical schools attached are appealing to charity so that medical education may be properly upheld in this great and wealthy country, and on the score that such hospitals will be at the service of the community as well as that of medical education. These great hospitals should, in my opinion, not be at the service of the ordinary patient but only at the service of the extra-ordinary, certified as such by the members of the medical profession. They indeed are worthy of being placed on a pedestal which will ensure the most careful investigation of the diseased states of a person and where every remedy shall be tested as to its merits. They should be enhanced in their position rather than be kept under or reduced to the level of those in which the recognised means of diagnosis and treatment of the day are duly and properly carried out. Indeed, they should be super hospitals if they are to attain the highest aim in front of medicine. Super hospitals properly and adequately run the country sorely needs—ordinary hospitals it must have and in adequate numbers here, there, and everywhere. Charity hospitals might continue to exist alongside public hospitals for all who care to avail themselves of them, but not under the guise that they might be sufficient to meet the needs of the people. Such is the selection that confronts us, and where is the organisation to consider it? None exists. The Royal Colleges of Physicians and Surgeons are absorbed in examining; the General Medical Council appears to me to fail to grasp the real qualifications needed by a young doctor, and it is compelled to spend much of its time in protecting the public against the doctor who will not abide by the ordinary rules of practice, and it was unfortunate that when a few years ago a Ministry of Health was constituted its amalgamation with the Local Government Board produced a mongrel of but little value either to local government or to public health. A change is imperative, and it may be that now the Ministry of Health will, in turn, split itself and give birth to disparate twins, a new local government service and a public health department in control solely of the medical services.

What is needed above all things is, I believe, a board of medical men, acquainted with the various aspects of medicine, to organise a new hospital service for the country, to regularise the existing institutions, to arrange for the provision of sufficient hospitals for adequate technical training of young doctors; to train young doctors of exceptional ability and promise to acquire further knowledge and extensive practice in medicine, in surgery, in midwifery, and in all special branches so that there may be a proper succession of well-trained doctors to fill the many offices that become vacant in the hospital services throughout the country. As changes are impending, now is the time to draw attention to the actual state of affairs. I am, Sir, yours faithfully,

Cambridge, Dec. 18th, 1929. JOSEPH GRIFFITHS.

MUTILATING OPERATIONS.

To the Editor of THE LANCET.

SIR,—On p. 1338 of your last issue an excellent report is given of the admirable speech made in the House of Commons by the Duchess of Atholl on the subject of mutilating operations performed, ritually, upon women and girls in certain of our Colonies or Dependencies. I do not propose to comment further upon this speech, but I am impelled to say something, with your permission, concerning mutilating operations performed, in this country, upon boys and young women. For some years past I have noticed, as many must do, the very obvious evidence of the gross mutilation that is inflicted upon young male children under the plea of circumcision as a necessary operation. (I firmly believe that the circumcision of male infants *is seldom, if ever, necessary, for the defect is not so* much in preputial redundance as in penile insignificance, a fault that is usually remedied in a few weeks or months by natural growth.) Nor is there any reason why the so-called adhesions which so often form the excuse for the operation should not be broken down by a little manipulation, or the judicious use of a lubricated director. This is not, however, my point. I refer rather to the effects of the operation in producing a state, literally, of gross mutilation, by the time the unfortunate boy, or youth, has reached puberty.

To what extent the gross mutilation that is the frequent result of the careless performance of circumcision in early infancy interferes directly with due performance of sexual function I cannot say. But no physician, who being interested in the of Pensions. For many years he had been keenly interested in politics, and after the war he twice stood as a Parliamentary candidate in the Liberal interest, but without success.

Sir William Milligan was fortunate in his home life, and his large family of brothers and sisters was a singularly united clan. He spent perhaps the happiest days of his life with a rod or a gun on his beautiful estate, Polmood, in Peeblesshire. Married, in 1890 to the daughter of Mr. James Anderson, of Liverpool, he leaves a son and a daughter.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Christmas Adjournment.

The House of Lords adjourned on Dec. 20th for the Christmas recess. They will reassemble on Jan. 21st. Among the Acts which received the Royal Assent before the adjournment was the Highlands and Islands (Medical Service) Additional Grant Act. The House of Commons adjourned on Christmas Eve.

The Mental Treatment Bill Considered on Report.

The Mental Treatment Bill was considered on Report in the House of Lords on Dec. 17th.

Power to Receive Voluntary Boarders.

On Clause 1 (which gives power to receive voluntary boarders) Earl Russell moved an amendment, which was agreed to, reducing the age at which persons could be received as voluntary boarders at the request of their parents or guardians from 18 to 16. Another amendment was agreed to omitting the word "unmarried," Earl Russell explaining that with the reduction of the age those words were unnecessary, because now by law young people could not be married under 16. These amendments would meet objections raised during the Committee stage.

Lord Danesfort moved a new subsection to ensure that a young person should not be sent to an institution on a doctor's recommendation which was old or out of date. It was, he said, founded on the analogy of Clause 5 (5) which made provision for putting a man into a place of mental treatment if he was incapable of volition. The recommendation of the doctor under Clause 1 of the Bill had to state that the person was likely to benefit from treatment for mental disorder. That might be true at or very shortly after the time when the person was examined, but if the recommendation were used a month or two after the examination the statement might be quite untrue, because the patient might have recovered, and possibly might no longer be likely to benefit by being put in a place for mental treatment. Therefore his proposal was that the medical recommendation should cease to have effect at the expiration of 14 days from the last date of examination.

Earl Russell said that the amendment was perfectly proper. The object was to avoid a stale recommendation. He would accept the amendment if it could be moved in the following form:—

> 4. "The medical recommendation shall cease to have effect for the purposes of this section on the expiration of fourteen days from the last date on which the person to whom the recommendation relates was examined by the medical practitioner for the purposes of making the recommendation."

Lord Danesfort agreed to the alteration and the amendment was carried.

A drafting amendment moved by Earl Russell, to omit the words "superintendent or other person in charge, or to the person with whom he is residing in single care," and to substitute "person in charge," was agreed to.

Persons Incapable of Volition.

Clause 2 deals with notice of reception, death, and departure of voluntary boarders, and makes provisions as to boarders who become incapable of volition.

On the motion of Earl Russell, a new Subsection (4) was agreed to, providing that if a voluntary boarder under 16 ceased to have any parent or guardian, or if his parents or guardians were incapable of performing, or refused or persistently neglected to perform their duty as such, the person in charge should report the circumstances of the case and the condition of the boarder to the Board of Control and the Board should consider the report and give such directions as they thought fit.

Clause 5 makes provision for treatment without certification of persons temporarily incapable of volition.

Earl Russell moved to amend Subsection 3 so as to provide that an application should be accompanied by a recommendation signed by two registered medical practitioners of whom one should be a medical practitioner (not being the usual medical attendant of the person to whom the application related) approved by the Board of Control for the purpose of making recommendations under this section, and the other should be, if practicable, the usual medical attendant of the person to whom the application related.

The Earl of Onslow said that as originally drafted the Bill said that it should be the family doctor, or if not then a person approved by the Board. In the event of there being no family doctor would two doctors be approved by the Board?

Earl Russell said that the clause would read that it should be a medical practitioner approved by the Board, and if practicable a family doctor. If there was no family doctor it would be any doctor that could be obtained.

Lord Merrivale said that Earl Russell was justified in what he was doing. He had been very much surprised on the previous day, among various communications from medical men, to receive one from a medical man with, he supposed, as large a private practice as there was in relation to matters of unsound mind and defective mentality, endorsing insistence that there should be some additional safeguard. He hoped that this additional safeguard would be agreed to.

The amendment was agreed to.

On the motion of Earl Russell another new Subsection (12) was agreed to as follows:—

> "A person received as a temporary patient shall not be detained as such for more than 28 days after the date at which he regains volition, unless in the meantime he again becomes incapable of volition."

He explained that this gave effect to Lord Cranbrook's proposal that a temporary patient should be discharged 28 days after recovering volition unless he relapsed in the meantime. The effect would be to give him more avenues of discharge than any other patient.

Power to Make Rules.

Considerable discussion took place on Clause 15, which gives power to make rules.

Earl Russell moved in a different form a new subsection which had been accepted in Committee, providing that rules made, under section 338 of the principal Act, after Jan. 1st, 1931, should be laid before both Houses of Parliament, and if within 21 days an address was presented to His Majesty by either House praying that a rule should be annulled it should be void.

On the suggestion of Viscount Brentford the date of Jan. 1st. 1931, was omitted, the noble Lord pointing out that power to make rules began long before the Act otherwise came into operation.

Viscount Brentford then moved a further amendment to the new subsection providing that the rules which not only the Ministry of Health but, under other clauses, the Board of Control were empowered to make, should not come into force where they modified or adapted this measure or any other enactment until the rule had been approved by each House of Parliament. He urged that if there was to be any change made in this legislation it should be done only by Parliament. In the subsection power was given to the department to make rules which would alter this Bill.

Earl Russell pointed out that the rule-making power which the subsection proposed would not enable them to alter the Bill. The rules, apart from the administrative rules, which would not come under Viscount Brentford's amendment, would not make new laws. They would be the most trifling adaptations of an old Act to new circumstances, and would in no sense alter anything that Parliament had agreed to. He hoped the House would not insist on the amendment.

After further discussion, Earl Russell suggested that the matter should stand over till the third reading for further consideration and consultation.

Viscount Brentford's amendment to the subsection was agreed to.

The report stage of the Bill was concluded.

The Third Reading.

On Dec. 19th the Bill was read the third time.

On Clause 2 (notice of reception, death and departure of voluntary boarders, and provisions as to boarders who become incapable of volition),

Earl Russell moved to omit from subsection (8) the words "in the opinion of the medical superintendent or such other person as aforesaid." These words, he said, were inserted at the instance of Lord Sandhurst on the committee stage, but they were found to be inappropriate to the Bill. The question of whether a patient was capable of volition or not was a question of fact, and it had to be ascertained, and was naturally founded on the opinions of the people who had observed it.

The amendment was agreed to and the Bill was passed.

SCOTTISH HEALTH VOTE.

On Dec. 16th the House of Commons went into Committee on a supplementary estimate of £10,050 for the *Scottish Department of Health, including grants in aid of* the Highlands and Islands Medical Service. The estimate was agreed to. The report stage of the same estimate was agreed to on the 17th.

HOSPITALS AND MOTOR ACCIDENTS.

On Dec. 18th the House of Commons went into Committee on the Road Traffic Bill, the Earl of DONOUGHMORE, Chairman of Committees, in the chair.

Third Party Insurance.

On Clause 34 (requirements in respect of policies for third party insurance),

Lord LUKE moved an amendment to provide that a third party risk insurance policy should ensure to any hospital treating any bodily injury caused by a motor accident payment of the cost of such treatment up to a maximum payment of £25. He said that in 1927 the hospitals of the provinces treated 20,000 in-patients and 89,000 out-patients in their wards as a result of motor accidents. The cost to those hospitals was approximately £230,000. The actual money received from insurance offices and patients was £26,000, so that to the extent of eight-ninths of the cases the hospitals bore the expense. If these cases were divided over all the hospitals of the kingdom evenly, probably it would not be so unfortunate for the few hospitals which now received these cases in excess—the hospitals near to the great trunk roads. All good motorists would pick up an injured person and take him to the nearest hospital, but the cure was usually at the expense of that hospital, and the hospitals were continually saying that these casualties from the roads were using the beds that had been provided for meeting local hospital needs. The maximum payment which he proposed was based on £4 per week for six weeks. That £4 was supposed to cover the out-of-pocket expenses of a hospital treating such a case, and the figures he had quoted would show that the average expense would not be greater than about £4. If such a risk were added to the present risk in anyone's policy the insurance offices said that the cost would only be about 1s. or 2s. additional. It seemed only *reasonable that hospitals should have this first charge on* the insurance, because if the hospitals were not handy to deal with these motor accidents motorists would be placed in a very difficult position.

Viscount KNUTSFORD said of course this amendment would not deal with all the accident cases brought to hospitals through motor accidents, but only with those where a person was insured against third-party risks, and where the accident was due to his negligence. It seemed really unfair that if a man was injured in an accident and was taken to a nursing home and treated by a doctor the insurer should pay the expenses as a liability in consequence of his negligence, but that if the same patient was taken to a hospital the insurer was not liable, because the hospital had no legal claim *to recover the costs incurred by it. In fact the* insurance company might refuse to pay, as it was not a legal liability, and they would be justified from the point of view of their shareholders. Although the treatment of these cases had increased enormously, and although this was a very serious burden on the hospitals, they made no complaint. They were only too glad to help injured people, but they did think that the present position was very unfair. He was sure that the amendment was a fair one.

Lord SOMERLEYTON, as one who had been connected for over thirty years with three central funds—the Saturday Fund, the Sunday Fund, and King Edward's Hospital Fund—said he desired to support the amendment.

Viscount BERTIE of THAME moved an amendment to the amendment to the effect that any surgeon or medical practitioner rendering first-aid in a motor accident should have a claim under the policy. He said that one often read in the press letters from doctors who lived nearby the scenes of frequent accidents stating that they were scandalously treated by persons who not only did not pay them but who went away with articles which had been lent to them and did not return them.

Lord STANLEY of ALDERLEY supported the amendment, but not the amendment to the amendment. He said that if the injured person were taken to a medical practitioner the claim of that medical practitioner would be part of the damages to be paid by the motorist and would be a proper claim against the insurance company. But that was not the case in regard to hospitals, he understood. Hospitals were voluntary associations, and as such could not institute an action or make any legal claim against the injured person, or against the person who caused the injury. If they were to deal voluntarily in future with motor casualties he thought that some of the small hospitals might find even greater difficulty in carrying on than at present.

Lord ATKIN said that it might be that there were insuperable difficulties in a hospital making a charge against a person who came for attention and who was treated by them, but he did not know what those difficulties were in law. He saw no reason why a hospital should not say that they would make a charge for any person who came to them who was injured in a motor accident, and that they would remit that charge if in fact it was not covered by insurance. If that were done the object of the amendment would be covered. If there were insuperable difficulties the real remedy was to make some such provision as that any person who had been injured by the negligence of a motorist should be entitled as part of his damages to recover a reasonable sum, not exceeding £25, which he might have paid, whether legally liable or not, to a hospital for treatment of his injuries. That would enable him to recover *from the insurance company. He doubted whether that* would mean any extra premium, because medical attention was always one of the elements in the damages which an insurance company laid themselves out to pay. The form of provision contained in the amendment would be very difficult to enforce.

Lord DANESFORT supported the amendment. The point raised by Lord Atkin was a good technical point, but was only technical. All that would be necessary would be to change the form of the amendment to meet it.

Lord EBBISHAM, in supporting the amendment, said that he had some experience in connexion with four small hospitals in Surrey. They found that in the last completed year an expenditure had been made for patients injured by motor-cars, but resident outside their locality, of at least £2000. A great injustice was being done to hospitals throughout the country.

The Government's Reply.

Earl RUSSELL, replying for the Government, said that he was aware of the grievance of the hospitals in this matter. It had become much more acute in the last two or three years. But this particular amendment in this particular part of the Bill was not the way to remedy the grievance. It would be inconsistent with the general scheme of insurance in Part II. of the Bill and it would not be by any means the best way to do it. It would not include all cases. There seemed to be in their lordships' House a practically unanimous feeling that something of this sort should be done. He suggested that the proper course would be to draft a separate clause which would provide in one way or other, not for the insurance only of some persons who were injured, but for the insurance of all persons who were injured—at any rate of all motorists. If Lord Luke and Lord Knutsford would confer with him and his advisers before the Report stage he would see if a separate clause could be drafted to meet the case. There was only one word of warning he would utter for the consideration of those interested in hospitals. If once a hospital began to receive contributions from any source in a manner which was not voluntary it seemed to him that it would be altering its character in a way which might be embarrassing and which might in the end, if the income from that source was considerable, expose it to some form of public management.

Viscount BRENTFORD, speaking on behalf of the British Hospitals Association, said he hoped that Earl Russell would approach this matter from the point of view of Lord Luke's amendment and not from the point of view of an imposition of a certain sum per head on motorists to raise a fund. What was needed was to enable the hospitals to do what the ordinary doctor or the ordinary nursing home could do.

Earl RUSSELL said that he proposed to consider the matter with a perfectly open mind and to consider any suggestions from those able to make them with a view to producing the best agreed clause, if one could be drawn.

Viscount CECIL of CHELWOOD said that the grievance would not be dealt with by approaching it in the manner proposed.

Viscount BRENTFORD: Why?

Viscount CECIL: Because the beds are actually filled. That was the real point. Country doctors would tell them pitiful stories of how the poor were utterly unable to get hospital treatment because the hospitals were absolutely filled with motorists at a certain period of the year.

Replying to Viscount BERTIE, Earl RUSSELL said that he thought that doctors who rendered assistance to these cases were protected, if they were entitled to sue.

The amendment and the amendment to it were both withdrawn.

The Bill passed through Committee.

The National Radium Fund.

On Dec. 10th, on the motion for the Second Reading of the Consolidated Fund (No. 1) Bill,

Sir Kingsley Wood said he wished to deal with a matter which had aroused a considerable amount of interest not only in the House, but outside, in relation to a considerable sum of money raised for the National Radium Fund. A large number of people had looked with the greatest hope and many of them with a good deal of anxiety to the use to which that fund would be put. He (Sir Kingsley Wood) was not questioning the belief that a great deal of good might be accomplished by the use of this large sum of money. He supposed that cancer was one of the most terrible diseases that afflicted mankind. The use of radium in the treatment of cancer, at any rate in its early stages, was one of the most hopeful methods. This considerable sum of money had been vested in the hands of specially constituted trustees who had been very carefully chosen. He had not seen a word of criticism in relation to the men who were serving as trustees of the fund. He admitted at once in putting the question as to what had been done and what purchases of radium had been made that there was very great difficulty in relation to the purchase of radium in this country at the present time. He understood that the only place to which the trustees could go to purchase radium was the Belgian Congo. That raised a very important point of view as to the outlook of the trustees. He agreed that unless they were very careful they might very well be held up and have to pay a very high price for radium.

Mr. Kelly: Why not go to Canada?

Sir Kingsley Wood said that that was one of the difficulties of the position. It was stated in the report upon which this question was largely founded that attempts were being made to find radium in other countries in the world and hopes were held out that radium might be found in the British Dominions. He thought there could be nothing finer for mankind, especially mankind suffering from a terrible disease like cancer, if it was possible to find radium in any other country than the one he had mentioned. He would like to know how much money had been expended in the purchase of radium in this country and whether it had been possible to obtain radium in any of the Dominions or any foreign country other than the Belgian Congo.

Miss Susan Lawrence (Parliamentary Secretary to the Ministry of Health) said that she could not reply at any length on this question. The Radium Trustees were not appointed by the Ministry of Health but by Royal Charter. Therefore, the Ministry of Health was not responsible for the work of the Radium Commission in so direct a way. It was an independent body set up by Parliament and would present an annual statement and accounts in a short time. In reply to the specific questions put by Sir Kingsley Wood she might say that they had agreed to purchase 10 grammes of radium at $50 per milligramme from the Union Minerale of Belgium, and they had another 4 grammes already in their possession with option to purchase. All the radium had been purchased from the Belgian company.

The Bill was read a second time.

HOUSE OF COMMONS.

Wednesday, Dec. 18th.

Overcrowding in Greater London.

Mr. Mills asked the Minister of Health if his attention had been called to the decreasing sleeping accommodation to the acre in London by the destruction of dwelling-houses and their conversion into shops and factories; whether he was aware that in many areas of London the sleeping accommodation had reached the density of 90 to the acre; and what steps he proposed to take to stop this danger to the inhabitants of inner London.—Miss Lawrence (Parliamentary Secretary to the Ministry of Health) replied: The difficulties of housing the population of Greater London were considered by the Royal Commission on the Local Government of Greater London. The proper control of development in Greater London is a matter which is being considered by the Greater London Regional Committee. I may add that my right hon. friend hopes to introduce legislation extending town-planning powers to build up areas.

After-care of Mental and Physical Defectives in Scotland.

Dr. Forgan asked the Secretary for Scotland the total amount of Government grants made last year to committees in Scotland concerned with the after-care of mental and physical defectives; the number of the committees among which this amount was divided; and the average sum received by each.—Mr. Adamson replied: The total amount of Government grants made last year to societies in Scotland assisting and supervising uncertified mental defectives was £750. Of this sum £600 was paid to a central association, with headquarters at Paisley, which operates through local care committees in various parts of Scotland, and £150 to a society in Edinburgh. Of the £600 grant to the central association a sum of £200 was allocated last year to 11 local care committees—an average of approximately £18 each.

Thursday, Dec. 19th.

Health Insurance Administration.

Mr. Llewellyn-Jones asked the Minister of Health whether he would furnish a list of advisory or other committees set up by the Ministry of Health in connexion with the administration of national health insurance or of public health generally since the commencement of 1925; and whether he would indicate on which of these committees provision had been made for the inclusion of members from Wales, including Monmouthshire, and the number of such members on each committee.—Mr. Greenwood replied: I am not in a position to reply specifically to the second part of the question, since I am advised that in many instances it has not been considered relevant to the object for which the committee was set up to inquire whether all or any of the members could be considered to belong to particular parts of Great Britain. The following is the list of committees set up by the Ministry of Health in connexion with the administration of national health insurance or public health generally since the commencement of the year 1925:—

Committee on Post-Graduate Medical Education; Committee on Vaccination; Dental Benefit Joint Committee—which has now been replaced by the Dental Benefit Council; Advisory Committee under Therapeutic Substances Act, 1925; Medical Advisory Committee on Decennial Revision of International List of Causes of Death; Committee on the Optical Practitioners (Registration) Bill; Advisory Committee under Article 41 of Medical Benefit Regulations, 1928; Committee on Ethyl Petrol; Committee on Training and Employment of Midwives; Committee on Maternal Mortality; Pharmaceutical Distribution Committee under Article 25 of Medical Benefit Regulations, 1928; Joint Advisory Committee on Pollution of Rivers and Streams; Advisory Committee on the Definition of Drugs for the Purposes of Medical Benefit under the National Health Insurance Acts.

Nursery Schools.

Mr. Day asked the President of the Board of Education how many new nursery schools had been approved by the Board during the previous 12 months.—Sir Charles Trevelyan replied: Fourteen new nursery schools have been approved by the Board since Nov. 1st, 1928.

Overcrowding of Public Mental Hospitals.

Mr. Sorensen asked the Minister of Health what action he was taking to prevent the present overcrowding of public mental hospitals.—Mr. Greenwood replied: Though there is a shortage of accommodation in public mental hospitals, there are relatively few cases of serious overcrowding. The position has already received my attention. Approval has been given to certain proposals for extending mental hospital accommodation, and others are under consideration. It is anticipated that these extensions will largely meet the present shortage; and further alleviation of the position may result from the survey of institutional accommodation which may become available under the Local Government Act.

Care of Mentally Deficient Children.

Mr. Sorensen asked the Minister of Health what action he was taking to provide suitable accommodation and care for the many cases of mentally deficient children who had been recommended for institutional treatment by mental deficiency committees but who were not receiving it.—Mr. Greenwood replied: I am aware of the existing inadequacy of institutional accommodation for mental defectives, both adults and juveniles, and local authorities are being urged to carry out their statutory duty to provide institutional accommodation.

Hours of Industrial Employment.

Lady Cynthia Mosley asked the Minister of Labour when she would introduce a Bill for the regulation of hours in industry.—Miss Bondfield replied: The Hours of Industrial Employment Bill is in course of preparation.

Replying to a further question by Mr. Louis Smith, Mr. Greenwood said he hoped to introduce the Bill on an early day after the Christmas recess.

Inspection of Vivisection Experiments.

The Duchess of Atholl asked the Home Secretary the number of visits of inspection per annum paid on an average by the inspectors of experiments on living animals; and whether the dates of these visits were known beforehand to the persons conducting these experiments.—Mr. Short replied: During the five years 1924–28 inclusive, 3315 visits were made or an average of 663 per year. Of the total, 140 (or an average of approximately 20 a year) visits were made by appointment for the special inspection of premises; for interviews with applicants for a licence; or for discussing with licensees questions arising out of their work under the Act. In all other instances (8160) the visits were made without previous notice.

Unsplintable Glass in Public Vehicles.

Commander SOUTHBY asked the Home Secretary whether he would consider taking steps to make it compulsory for all hackney carriages and other vehicles plying for hire to be fitted with unsplinterable glass.—Mr. SHORT replied: The jurisdiction of my right hon. friend in this matter is limited to London. He has considered it in consultation with the Commissioner of Police and he is afraid that it is not practicable at present to enforce the use of unsplinterable glass in public service vehicles generally on account of *the cost, but the matter will not be lost sight of.*

Medical News.

UNIVERSITY OF OXFORD.—At recent examinations the following candidates satisfied the examiners in the undermentioned subjects:—

Medicine, Surgery, and Obstetrics.—J. A. Brown, L. J. Clapham, C. M. Duncan, W. B. Fiddian-Green, J. K. Marshall, *G. St. L. Myles, R. S. B. Pearson, C. R. Salkeld, G. Secker* Walker, W. B. Williams, Annie D. M. Adams, and Ruth Sandeman.

Pathology.—R. E. Adam, I. M. Bell, W. D. W. Brooks, G. H. Buck, J. M. Cribb, F. R. Crookes, Shelton Durham, N. A. Gillespie, Newton Heath, G. W. Hinchliff, J. E. Jenkins, H. de B. Kempthorne, G. B. Malone-Lee, J. H. Peel, W. S. Tegner, H. A. Treble, F. M. Trefusis, O. S. M. Williams, and Elspeth W. Smellie.

Forensic Medicine and Public Health.—H. H. Aitchison, Fairfax Bell, W. D. T. Brunyate, G. H. Buck, J. L. Clapham, C. M. Duncan, W. B. Fiddian-Green, C. R. Greene, Arthur Guirdham, Francis Hawking, W. H. McMenemey, J. K. Marshall, W. E. S. Merrett, R. D. Newton, J. N. *O'Reilly, N. C. Parfit, R. S. B. Pearson, F. M. Trefusis,* Amy C. E. Clarke, and Victoria M. Robinson.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were successful:—

M.CHIR.

F. J. Milward.

THIRD EXAMINATION FOR M.B. AND B.CHIR.

Part I., Surgery, Midwifery, and Gynæcology.—G. G. Allan, G. N. Bailey, G. O. Barber,* R. E. Barnsley, J. H. Bentley, R. M. Bolam, W. V. Bowman, A. D. D. Broughton, A. C. Crooke, A. M. Cunningham, H. Curtis, M. Ellis, R. B. Floyd, M. S. M. Fordham, I. J. Franklen-Evans, A. W. Franklin, *A. S. Hall, P. E. T. Hancock, A. G. J. Harris, J. E. M.* Harrison, F. T. J. Hobday, W. V. Howells, E. H. Hudson, C. G. Jobbins, M. M. StG. Johnstone, J. G. Jones, H. V. Knight, E. Landau, R. S. C. McDade, S. McDonald, A. P. McEldowney, R. W. Malim, C. E. P. Markby, R. A. Maynard, B. C. Nicholson, G. L. Ormerod, R. G. Orr, V. P. Paxon, J. O. Poynton, C. H. Prowse, T. G. Reah, G. H. Sanderson, J. E. Semple, R. H. B. Snow, G. H. G. Southwell-Sander, R. S. Stacey, R. T. W. Starkie, B. C. Thompson, C. P. K. Toland, F. S. Winton, C. H. England, and D. P. Firmin.

*Passed in Surgery only.

Part II., Physic, Pathology and Pharmacology.—R. Anderson, A. R. Banham, C. M. Barker, D. W. Bawtree, J. V. Broad, A. T. Curnow, C. J. M. Dawkins, Digges la Touche, R. H. *Dyer, J. H. L. Easton,* P. H. Fox, *S. E. F. Gooding,* G. J. Gross, A. H. Gurney, W. Heath, A. C. de B. Helme, J. S. Hensman, G. Herbert, H. P. Hutchinson, T. C. Jameson Evans, C. G. Jobbins, E. R. Keeble, R. W. Knowlton, C. L. Lander, R. W. McConnel, S. R. Matthews, R. B. Mayfield, E. J. Neill, T. N. Parish, J. A. Pocock, C. D. Politeyan, R. B. Pringle, A. W. Williams, J. K. Wilson-Pepper, G. N. Wood, F. G. Wood-Smith, B. Wright, and M. A. Willcox.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial on Dec. 20th the following degrees were conferred:—

M.D.—Flora H. M. Calder, **T. C. Mitchell, **R. M. Murray-Lyon, †Eustace Russell, G. S. Scott, *Ta-Ming Tso.

Ch.M.—**Alice Bloomfield.

M.B., Ch.B.—W. S. Anderson, Reginald Austin, Ismay Bannerman, T. M. Beveridge, G. F. Bradbury, R. M. Bremner, J. F. C. du Toit, F. G. M. Fraser, E. E. Goldman, James Gorman, D. H. Hooper, E. G. Hurd-Wood, Isidor Kaplan, H. I. Labouri, L. E. Lucas, K. C. Mackenzie, A. G. M'Laren, D. J. A. MacLean, Daniel Macleod, H. J. Melville, G. R. Parker, J. L. Parker, R. A. P. Paul, G. A. G. Peterkin, J. C. Robertson, †Nirodbaran Talukder, Anne Tillema, and S. C. H. Watters.

Diploma in Psychiatry.—†T. A. H. Munro.

Diploma in Public Health.—†K. V. R. Choudari.

AWARD OF FELLOWSHIP.

The Syme Surgical Fellowship was awarded to Dr. Thomas Carlyle Mitchell.

* Commended for Thesis. ** Highly commended for Thesis.
† In absentia.

UNIVERSITY OF SHEFFIELD.—At recent examinations the following were successful:—

FINAL EXAMINATION FOR M.B., CH.B.

Part I.—K. G. A. Barlow, Clem England, N. B. Hallam, Firth Hudson, Constance N. Jenkinson, S. K. Panniker, and Allan Spencer.

Part II.—Abraham Cohen, R. B. Gould, Bessy Hatherley, and J. H. Wilbourn.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following were successful:—

M.CH. ORTH.

W. J. Eastwood, W. L. MacDonald, and J. F. Shepherd.

M.D.*

K. M. Cobban, L. Earlam, R. R. Evans, J. F. Galloway, and Mary S. Share-Jones.

FINAL EXAMINATION FOR M.B. AND CH.B.

Part II. (1923 Regulations).—M. L. Kaufman.

Part III. (1923 Regulations).—J. P. Flanagan, R. N. Johnson, I. Lipschitz, and J. L. Walker.

Part A. (1924 Regulations).—W. Dodd, J. J. M. Erskine-Young, M. Glynn-Morris, C. K. Holland, H. D. Owen, J. Polonsky, and H. E. C. Sutton.

Public Health.—D. I. A. Williams.

* To graduate July, 1930.

DIPLOMA IN TROPICAL MEDICINE.

S. D. Ahuja, R. E. Anderson, C. G. Booker, W. A. Bullen, *E. N. Callum, P. P. D. Connolly,* J. A. Cowan, G. Graham-Cumming, A. V. Greaves, G. S. Hale, A. T. Howell, C. N. Latham, J. E. McMahon, A. A. Miller, A. Rosenbloom, C. K. Row, R. N. Sewal, H. Singh, G. A. Talwrn-Jones, and H. N. Turner.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College on Dec. 18th, with Dr. J. Haig Ferguson, the President, in the chair, the following 23 candidates (out of 70 entered) who passed the requisite examinations between Sept. 26th and Oct. 4th, were admitted Fellows:—

Frans Bekker, Philip William Hulme Bleasdale, John Boyd Colquhoun, John Comrie, Cedric Duncombe, Andrew May Duthie, Duncan Hugh Fraser, Cecil Alexander Gardiner, Wallace John Gill, Alastair Livingston Gunn, Hukam Chand Gupta, James Haslam, Elinor Drinkwater Jackson, Laurence Henry Leggett, Arthur Cecil Liesching, Vivian Mercer Metivier, David Ritchie Paterson, John Edward Piercy, Manindra Nath Sarkar, Sher Singh, George Ferguson Skinner, Oscar John Stahl, and Ryno Stockenstrom Verster.

PRINCESSES AT HOSPITALS. — Princess Louise, Duchess of Argyll, recently opened a new wing of the Plaistow, E., Maternity Hospital and District Nurses' Home. The hospital now has 66 beds and is the fifth largest of its kind in London. The addition contains two wards of eight beds each, two single-bed wards, a labour ward, and infants' nursery. There has hitherto been such heavy pressure upon the accommodation that temporary beds have had to be in use continuously. The institution trains 200 midwives annually and 6000 mothers are attended every year. During the last decade the hospital's maternal mortality has been approximately 1 in 2000. The working expenditure exceeds £22,000.—Extensive additions to the South-Eastern Hospital for Children at Lower Sydenham were opened last week by Princess Marie Louise. The *out-patients' department and the nurses' home have been* enlarged, rooms have been provided for the medical and surgical staffs, for sunlight and massage treatment, and for children being treated for tonsils and adenoids.

Appointments.

Bristol General Hospital: WOOD, D., F.R.C.S. Eng., Honorary Surgeon; GRIFFITHS, S. J. H., M.B., Ch.B. Bristol, F.R.C.S. Eng., Honorary Assistant Surgeon; BURGESS, N., M.D., B.Chir. Camb., M.R.C.P. Lond., Honorary Assistant Physician in the Skin Department; TAYLOR, A. L., M.D., Ch.B., Leeds, Honorary Pathologist; KETTLEWELL, N. H., L.D.S. R.C.S. Eng., L.M.S.S.A. Lond., Honorary Dental Surgeon.

City of London Maternity Hospital: PRICE, J. A., M.B., B.Ch., Belf., Resident Medical Officer; SIMMONS, R. W. A., B.M., B.Ch. Oxf., Assistant Resident Medical Officer.

Queen Charlotte's Maternity Hospital: HUGHES, TOM. L., L.R.C.P. Lond., M.R.C.S., Senior Resident Medical Officer; JENNINGS, H. T., M.B., Ch.B. N.Z., F.R.C.S. Edin., Assistant Resident Medical Officer.

Certifying Surgeons under the Factory and Workshop Acts: FARMER, M. L., M.B., Ch.B. Liverp. (Shefford, Bedford); MEAD, G. H., L.R.C.P. Lond., M.R.C.S. (Eckington, Derby); SMITH, E. F., M.B., B.S. Lond. (Wokingham); and CREIGHTON, J. A., M.B., C.M. Glasg. (Calvert, Buckingham).

Vacancies.

For further information refer to the advertisement columns.

Acton Hospital, W.—Res. M.O. £150.
Belfast, Joint Nursing and Midwives Council, Northern Ireland.—Examiner of Midwives.
Birmingham, Dudley-road Hospital.—Gynæcologist and Obstetrician. £700.
Birmingham, Monyhull Colony, King's Heath.—Res. Asst. M.O. £250–£350.
Birmingham, Selly Oak Hospital.—Two Cas. O.'s. Each at rate of £200.
Blackburn and East Lancashire Royal Infirmary.—Res. H.P. £150.
Bolton, Townley's Hospital, Farnworth.—Second Asst. M.O. £225.
Bootle Borough Hospital.—Hon. Laryngologist and Aurist.
Bradford Children's Hospital.—H.S. and H.P. Each £120.
Bradford Royal Infirmary.—Res. Surg. O. £250.
Burnley, Victoria Hospital.—H.S. At rate of £125.
Canterbury, Kent and Canterbury Hospital.—H.S. and H.P. Each at rate of £125.
Cardiff, Prince of Wales' Hospital.—H.S. for Crossways Country Branch Orthopædic Hospital. £120.
Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. At rate of £120 and £100 respectively.
Charing Cross Hospital, Strand, W.C.—Non-resident House Anæsthetist.
Durham County Mental Hospital.—Jun. Asst. M.O. £350.
Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.
Great Yarmouth County Borough.—Asst. M.O.H. and Asst. Tub. O. £600.
Hospital for Sick Children, Great Ormond-street, W.C.—Part-time Jun. Cas. O. At rate of £150. Also Clin. Asst. M.O. for Venereal Dept. £1 1s. per session.
Hull Royal Infirmary.—Third H.S. Also Asst. H.P. At rate of £150 and £130 respectively.
Leeds University.—Tutor in Obstetrics and Gynæcology. £475.
London Female Lock Hospital, 283, Harrow-road, W.—H.S. At rate of £150. Also Hon. Obstet. Surg.
London Hospital Medical College, Mile End, E.—Liddle Triennial Prize. £120.
Manchester, Ancoats Hospital.—Asst. Pathologist. £350.
Manchester, Babies' Hospital, Burnage-lane, Levenshulme.—Sen. Res. M.O. At rate of £125.
Manchester, Salford Royal Hospital.—H.S. for Orthopædic Dept. At rate of £125.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Northampton Education Committee.—Asst. School Dentist. £150.
Queen Mary's Hospital for the East End, Stratford, E.—Cas. O. £150. Also Hon. Asst. S.
Redruth, Cornwall, West Cornwall Miners, and Women's Hospital. Res. M.O. £200.
Rochdale Infirmary and Dispensary.—Jun. H.S. £175.
St. John's Hospital, Lewisham, S.E.—Radiologist.
St. Mary's Hospital, W.—Asst. Pathological Chemist. £300.
Sheffield, Jessop Hospital for Women.—Two Asst. H.S.'s. Each at rate of £100.
Southampton County Borough.—School Dentist. £150.
Swansea County Borough.—Asst. M.O. £600.
Walsall General Hospital.—Cas. H.S. At rate of £120.
West London Hospital, Hammersmith-road, W.—Asst. Dental. S.
Westminster Hospital, Broad Sanctuary, S.W.—House Anæsthetist. At rate of £100.
Wigan Infirmary.—Third H.S. £150.

Births, Marriages, and Deaths.

BIRTHS.

FINLAY.—On Dec. 14th, at The Gables, Honiton, Devon, the wife of Dr. J. E. Finlay, of a son.

MARRIAGES.

JONAS—PETLEY.—On Dec. 19th, at All Saints', Ennismore-gardens, William Howard Powning Jonas, B.A., M.R.C.S., L.R.C.P., of "Brooklands," Hemel Hempstead, Herts, to Kathleen Isabel, only daughter of Mr. and Mrs. C. Ralph Petley, of Vert Lac, Lausanne, Switzerland.

DEATHS.

CANDY.—On Dec. 16th, George Spence Candy, M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., aged 44.

DWYER.—On Dec 16th, at "The Mount," Lapworth, Warwickshire, after a short illness, Henry Hamilton Dwyer, L.R.C.P. & S.I., L.M.

EGAN.—On Dec. 11th, at Kingston, Jamaica, Major William Egan, R.A.M.C., D.S.O., O.B.E.

MILLIGAN.—On Dec. 19th, at a nursing home, Sir William Milligan, M.D., LL.D., of Westbourne, Rusholme, Manchester, and Polmood, Broughton, Peeblesshire.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.

Prince of Wales's General Hospital, Tottenham, N.

The same arrangements will be made as were announced in THE LANCET of Dec. 14th.

Notes, Comments, and Abstracts.

THE USES OF X RAYS.

THE exhibition of radiography just concluded by the Royal Photographic Society of Great Britain is to be the first in a series illustrating the "uses of photography in the service of man"; it attempted especially to illustrate the history and development of the scientific and industrial value of X rays. Various forms of early X ray tubes, as well as recent apparatus, were lent by the Davy Faraday Laboratory, by Mr. Cuthbert Andrews, and Mr. Geoffrey Pearce. Dr. W. H. George lent an exhibit demonstrating the use of photographic grids in X ray crystallography.

The medical section showed a number of radiograms of those surgical and medical conditions in which diagnosis is materially helped by use of X rays. Advances in dental work included simultaneous photography of the profile and the jaw, so that artificial teeth may be made to conform to the normal shape of the face as much as possible. Excellent photographs demonstrating the use of tetraiodophenolphthalein in cholecystography and collargol in pyelography were shown, while the uses of barium in defining œsophageal obstruction, carcinoma of the stomach, and intestinal conditions of various kinds, were illustrated. The number and variety of photographs shown was somewhat limited from a medical point of view, but as the intention was to demonstrate the photography rather than the innumerable occasions of its utility, this was not surprising. The radiograms in this section were lent by Kodak, Ltd., by Mr. H. T. Ferrier, and by the Ilford X ray Department.

In the section devoted to transparencies various recent improvements in apparatus were demonstrated, including a portable X ray apparatus made by the "Solus" Electrical Company. Mr. Herbert Flower lent an interesting series of negatives showing X ray exposures versus screen exposures on various bone subjects. The X ray exposures showed a marked gain in contrast without loss of detail. Photographs of old forms of apparatus, including early patterns of couches in which the tube was unprotected, were sent by Messrs. Schall and Son, Ltd., and could be compared with the latest types which were shown with the transparencies.

The use of X rays in detecting flaws in metal castings was demonstrated in the industrial section, and the value of this one function in the service of man is hard to estimate. It was unfortunate that the absence of a photographic aspect excluded deep ray therapy from representation in an exhibition designed to demonstrate the value of the Röntgen ray.

TWO DIARIES FOR 1930.

THE Anglo-French Drug Company (238A, Gray's Inn-road, London, W.C. 1) have sent us a copy of their block diary for 1930, measuring 6 by 4½ inches, and showing a page to a day. It serves as a useful accessory to the writing table, and attached to the inside of the front cover is a concise list of the pharmaceutical products manufactured and distributed by the firm.—We have also received the medical diary issued by Messrs. Burroughs Wellcome and Company. It comprises 404 pages, measuring 6¼ by 3¾ inches, bound in a case, and gives therapeutic notes, an index of diseases and treatments, symptoms and treatment of poisoning, notes on diet, and other useful information, including a list of the firm's well-known "Tabloid" products. Either of these diaries may be obtained on application.

Radium Needles.—Prof. F. L. Hopwood writes that in the paper presented by Miss Smallman and himself at the Radiological Congress (THE LANCET, Dec. 14th, p. 1270) it was stated that with half a gramme of radium distributed in needles and containers 800 cases were treated in *two* years (not one year) at St. Bartholomew's Hospital.

THE address of the National Association for the Prevention of Tuberculosis is now Tavistock House North, Tavistock-square, London, W.C. 1.

A HOSPITAL'S CLAIMS FOR PAYMENT.—Some time ago the statutes of the Royal Salop Infirmary at Shrewsbury were altered to enable the governors to charge motor accident patients with the cost of their treatment and maintenance. It is now officially reported that the result has been disappointing. Sixty-four such patients have since been discharged, and were presented with accounts amounting to £808. Eight patients only have paid, the entire refund amounting to £94 11s.
